"I have not yet received the Report from the Commissioners appointed to inquire into the state of Municipal Corporations, but I have reason to believe that it will be made, and that I shall be enabled to communicate it to you at an early period.

"I have appointed a Commission for considering the state of the several Dioceses in England and Wales, with reference to the amount of their revenues, and to the more equal distribution of episcopal duties; the state of the several Cathedrals and Collegiate Churches with a view to the suggestion of such measures as may render them most conducive to the efficiency of the Established Church; and for devising the best mode of providing for the cure of souls, with reference to the residence of the Clergy on their respective benefices.

"The especial object which I have in view in the appointment of this Commission is to extend more widely the means of religious worship according to the doctrines of the Established Church and to confirm its hold upon the veneration and affections of my people.

"I feel it also incumbent upon me to call your earnest attention to the condition of the Church of Scotland, and to the means by which it may be enabled to increase the opportunities of religious worship for the poorer classes of society in that part of the United Kingdom.

"It has been my duty on this occasion to direct your consideration to various important matters connected with our domestic policy.

"I rely with entire confidence on your willing

co-operation in perfecting all such measures as may be calculated to remove just causes of complaint, and to promote the concord and happiness of my subjects.

"I rely also with equal confidence on the caution and circumspection with which you will apply yourselves to the alteration of law which effect very extensive and complicated interests, and are interwoven with ancient usages to which the habits and feelings of my people have conformed.

"I feel assured that it will be our common object, in supplying that which may be defective or in renovating that which may be impaired, to strengthen the foundations of those institutions in Church and State which are the inheritance and birthright of my people; and which amidst all the vicissitudes of public affairs, have proved, under the blessings of Almighty God, the truest guarantees of their liberties, their rights, and their religion."

His Majesty then retired; a royal salute was fired, and on his return to the palace the same mixed demonstrations of popular sentiment were observable.

The House adjourned till five o'clock, when the Lord Chancellor took his seat on the Woolsack, and his Majesty's speech was read.

TOULON, Feb. 24.—We are assured that instructions have been sent to the Commander of the Bellona frigate, which has just left our port for Mahon, to remain there, in order to keep in observation the American squadron which is to rendezvous in that port. On the same account, orders have been issued for several maritime armaments to be held in readiness to act until the issue shall be known of the pending discussions between France and the United States.

#### PORTUGAL.

LISBON, Feb. 23.—The change of Ministry which has been in contemplation for some time has at length taken place. The Duke of Palmella has accepted the office of Minister for Foreign Affairs; the Bishop of Coimbra has been raised to the peerage, and, in consequence, has resigned the Home Department, which has been given to Freire—the latter has been, as you know, Minister of Marine; and Count Villa Real has been appointed to the office thus left vacant.

We are here perfectly quiet. The Cortes and the Government appear, at present to go in present in perfect union.

#### GREECE.

ATHENS, Jan. 21, 1835.—The latest intelligence received from the Morea represents that peninsula to be in a very disturbed state; and it appears that in the districts of Messenia, which were last year the scene of civil discord, discontent is most openly manifested.

The basis of a treaty have been entered into between our government and Mr. George Cochrane, for the establishment of a line of steam-packets between Marseilles, Malta, Athens, Lyta, and Turkey.

#### TURKEY.

Tremendous Conflagration.—Two thirds of the city of Adrianople, the quarter inhabited by the Greeks, was on the 24th Feb. destroyed by fire. The value of English manufactures destroyed is said to have amounted to 2,000,000 piastres.

Advices from Constantinople to 28th January state that the insurrection in Albania was at an end. The troops were returning.

LONDON, MARCH 5th.—The following intelligence from Levant has been brought by a vessel which left Alexandria on the 23d of January, and has just arrived in France, after touching at Malta—"As soon as the departure of the English squadron was known at Constantinople, three Russian ships of war passed the Dardanelles, and have, it is said, cast anchor at Mytilene. A fourth ship, which left the straits at the same time, is gone to take up her station at Tenedos. The Admiral at Malta has sent notice of these movements to London. On the 28th of January, the squadron of Josias Rowley, had been several days at Malta. The retreat of the English squadron is attributed to a promise made by Russia to the Porte, to relieve it from the importunate presence of the English—a promise, the fulfilment of which is due to the good will of the Wellington Ministry."

PARIS, March 5.—The new Ambassador from the Ottoman Court to that of London, Nouri Effendi, arrived at Paris yesterday, and alighted at the hotel of the Turkish Embassy.

On the 21st ult. Don Miguel was at Rome, leading a retired life.

Sir Charles Manners Sutton, the discomfited candidate for the Speaker's Chair, had been called to the peerage by the title of Lord Canterbury.

SIR FRANCIS BURDETT, the long tried friend of the people, has given great umbrage to his constituents, by voting for the re-appointment of Sir C. M. Sutton, as Speaker of the House of Commons.

Mr. Cobbett, after stating that he could not vote for Mr. Abercromby, left the House.

A debate had taken place in the house on Canada affairs, in which the ministers had expressed their intention to send out a commissioner to Canada, with full powers to act on the questions which agitated that part of the British dominions.

The *Morning Herald*, which originated the gossip about the Queen, stated, on Friday,—"We have authority to say that there is no truth in the statement which has lately been circulated as to the interesting situation of her Majesty the Queen."

The price of gold is raised; it is now 3l. 17s. 10 1/2d. per ounce.

Raise of the Cotton Trade.—In the beginning of the reign of George the Third (1760) this trade gave employment to 40,000 persons, and the value of the goods produced was 600,000l.—It now employs not less than 1,500,000 persons, and the value of the goods produced exceeds thirty-one millions. The cotton yarn annually spun in England would, in a single thread, girdle the globe 203,775 times; it would reach fifty-one times from the earth to the sun, and it would encircle the earth's orbit eight times and a half. —[Athenæum]

HENRY HUNT.—Well known as one of the greatest demagogues that ever lived, died recently in England. The London Standard says, he "was seized, about three weeks ago, with a violent attack of paralysis, when in the act of stepping from his phaeton, which deprived him of the power of speech, and threatened immediate dissolution; but, by the prompt administration of active remedies, the immediately alarming symptoms were subdued, and his friends, who were best acquainted with his vigorous constitution and powerful frame, indulged hopes that years might be added to his life, although his medical attendants gave no expectations of his ever recovering the use of his left side. During his illness Mr. Hunt enjoyed the perfect use of his faculties, and maintained a composed and even cheerful demeanour throughout. On Tuesday last, a return or unfavorable symptom rendered it necessary to call in the aid of Dr. Lightfoot, from Winchester, who abandoned all hopes of his recovery, and since that day he gradually sunk till Friday, when upon his busy and active life the scene closed forever. He had recently left London, on a journey of business into the west of England. Mr. Hunt was lord of the manor of Glastonbury, in Somerset, and possessed some property in the city of Bath, as well as in the vicinity of Bristol. He had been bred a farmer in Somerset, and was afterwards a brewer in Bristol; and during the last twenty-five years had been a Radical Reformer. He died possessed of but a small property. He was an exceedingly good farmer, and a man much devoted to field sports. He was considered a first-rate shot, and a skilful angler; and as a fly-fisher, was equal to the celebrated Isaac Walton.

The name of Henry Hunt will long be remembered, in association with the "Manchester Massacre"—he was chairman of the meeting on that occasion. He was the session before last M. P. for Preston—and latterly extensively engaged in manufacturing blacking.

LONDON, March 3.—From the following extract which is taken from the *Great Journal* of the 24th ult., it will be seen that public opinion is not very favorable to the idea of a speedy settlement of the American claims:

"Several applications for letters of marque

have been sent from our department to the ministry. The Minister of Marine has replied to one of these applications, that in the uncertainty which prevails respecting the issue of the difference with America, he could not at present positively accede to this application, but that he would take due notice of it, promising to pay attention to it if occasion should arise."

PARIS, March 3.—There are terrible accounts in the *Moniteur* of the consequence of the gale on the African coast.

The Duke of Gordon had been robbed of jewelry to the amount of £10,000.

A letter from Florence, of the 9th of February, says that on the 7th, at 50 minutes past 7 in the evening, several shocks of an earthquake had been felt there. No damage had been done, except some trifling injury to the Castles of Lucio and Vecchio, nor had any persons been hurt.

COPENHAGEN, Feb. 28th.—I hasten to inform you that the address I spoke of, signed by near 600 individuals, most of them persons of high standing in the esteem of their fellow citizens, has been—not carried up by a deputation, but—smuggled by a back door into the palace of the King. His Majesty has been pleased, through his medium, to reply to the petition of his subjects in the terms following:—

"We have seen with surprise that a body of our dear and faithful subjects have petitioned us to make an alteration in the existing law of the press; for, as it constantly has been the object of our paternal solicitude to do all that lay in our royal power, tending to promote the welfare of the State, and the People, so, likewise, none but ourself alone can be in condition to judge of what is to the true good and benefit of both—an object which it will be our care to promote, in the time to come, with the same zeal and unabated love for our people as heretofore. We pray God to take you into his holy keeping.

IMPORTANT FROM FRANCE.—The packet ship *Francis I.*, Capt. Castoff, from Havre, came up yesterday. She sailed from Havre on the 13th ult. The packet *Silvie de Grasse*, from this port, arrived on the 10th. The market for Cotton continued lively.

A letter from Paris of the 10th March, says—"We remain still without any Ministry being formed, and it appears that the difficulties rather increase than diminish. This is particularly to be regretted, as the report of the Committees on the American question is ready to be made, and is waiting only for a Ministry to present it. Let the Ministers be who they may, it will pass by a large majority.

[From the *Canton Register*.]  
Population of China.

The Roman empire, including the provincials and conquered nations, is said to have comprehended, under the Antonines, about 120 millions of inhabitants. The extent of its territory was fully equal to China proper; and although some of the provinces were only lately reclaimed from barbarian, and therefore by no means well cultivated, its ancient possessions in Europe, Asia, and Africa, were, if not superior, at least equal in populousness to China. From whence does then arise the disparity between 120 and 361 millions? Luxury, as well as the frequent wars may have thinned the population, but they cannot have reduced it to such odds.

In our humble opinion, we can cherish no doubts about the correctness of the imperial statement, that the numbers are according to a well authenticated census, as near to the truth as possible, but we state freely some difficulties, which wiser men than ourselves will be able to remove.

In Shing-king or Leao-tung, the imperial statistics, estimate the census to 949,003; now we have visited some districts of this territory ourselves, and with all allowances for mistakes, we suppose that the number of inhabitants must at least be four-fold. In Kirin, it is said that there are only 307,761 inhabitants. We know that this country is extremely thinly inhabited, but this census would only give 11 inhabitants to a square mile, which is incredible, on account of the continued influx of Chinese. In Taitshan

there are only 2398 families, which considering the numerous tribes living scattered throughout this extensive country, must be far below the truth. Perhaps those only who pay tribute, and serve in the militia, are included in the number. We will not now discuss the census of Kokonr and of Ele (the same remarks apply to this country) but merely intimate, that the numerous Mongul tribe is not comprised under the 361 millions!

So far as we have seen, the census is below the actual number, but in some provinces it is the reverse. But we are rather cautious to advance opinions, which might militate against facts, that give here the list of the extent and population of each province.

Pe-chih-le; extent, 58,949 square miles; inhabitants 27,990,874; upon each square mile 473. Shon-tung; extent, 65,104 s. m. inhabitants 28,958,764 upon each s. m. 515.

Keang-nan (the two provinces Keang soe Ganhwuy) extent, 92,961 s. m. inhabitants 72,011,560 upon each s. m. 774.

Shan-se; extent, 55,268 s. m. inhabitants 14,004,210; upon each s. m. 253.

Honan; extent, 65,104 square miles, inhabitants 23,037,171; upon each s. m. 354.

Keangsoe extent, 721,176 square miles, inhabitants 30,426,999; upon each s. m. 421.

Fokien; extent, square miles 53,480, inhabitants, 14,777,410; upon each s. m. 276.

Che-keang; extent, square miles 39,150 inhabitants 36,256,784; upon each s. m. 671.

Hoo-pih and Hoonan; extent, square miles 144,770, inhabitants 46,022,605; upon each s. m. 317.

Shense and Kan-suh; extent, square miles 154,008, inhabitants 25,420,381; upon each s. m. 164.

Sze-chuen; extent, 166,800, square miles, inhabitants 21,435, 678; upon each s. m. 128.

Kwang-tung; extent, 79,456 square miles, inhabitants 19,174,030; upon each s. m. 241.

Kwang-se; extent, 78,250 square miles, inhabitants 7,317,895; upon each s. m. 93.

Yun-nan; extent, 107,869 square miles, inhabitants, 5,561,320; upon each s. m. 51.

Kwei-chow; extent, 64,554 square miles, inhabitants 5,288,219; upon each s. m. 82.

We ask the political economist, whether 774 human beings can live upon one square mile, which is thrice the population of England, where only 225 live upon the same spot. If, however, the census of Ganhwuy and Keang-soo is correct, we are persuaded, that there is no spot upon the whole globe which is so thickly populated; nor can a larger number possibly live upon the same extent of territory. Keang-soo, moreover, is full of lakes, and has also considerable marshes, which are of course not arable. The utmost industry can subvert the cultivator, yet he has nothing to spare from his hard earned produce; and nevertheless both Gan-hwuy and Keang-soo have very largely to contribute towards the maintenance of the imperial court. Shan-fung and Che-keang are mountainous provinces, with many barren tracks and unproductive plains, yet according to the imperial census the former has 515 and the latter 671 inhabitants upon each square mile.—We allow the Chinese to be a most frugal people, who do not require half the extent of territory to maintain themselves as an European would need, to live in a state of comfort, but can 617 human beings find subsistence in so small a space? Surely if the imperial statistics are correct, the populousness of Keang-so, Gan-hwuy and Che-keang overthrows the theory of Malthus. Pihchile is apparently barren, but has nevertheless 473 inhabitants upon the square mile.

We are also at a loss to find out why Yan-nan should have fewer inhabitants than Kwei-chow, the most unproductive of all the provinces, nor can we make out why Kwan-tung and Honan, both possessing a dense population, should not have an equal number with Che-keang upon each square mile, whilst the former is only one third, the latter one half as populous.

It is not with a view to impeach the statements given in the Repository, that we write this, but we are anxious that our doubts should be solved for our own satisfaction. Upon the whole, we think that the total amount of 361 millions is not too much for the Chinese empire. It is very evident, that the Chinese are the most prolific

nation on the globe. Instead of conquering other nations like the Romans, they took possession by the numerical force of their population, colonized and spread until mountains and deserts prevent their farther progress. A nation like the Chinese, so numerous, guided by the same laws, attached to the system of the ancients, were more likely to abide the subjects of one prince, than the heterogeneous tribes who acknowledge the sway of the Romans. The striking characteristics, which doubtless constitute the Chinese nation a people distinct from all human kindred, contributed much to that unity of design, which caused them to abhor foreigners and to crowd under the protection of their native leaders.

Has China ever been so populous as it is now? Can a nation continue to increase in proportion, without absorbing finally all resources? These are the questions which we should fairly ask, to come to a satisfactory conclusion. The rising generation is at the present moment so great, as to frighten the mandarins, who tremble at the prospects before them. Fully persuaded, however, that in the providence of God, the population keeps pace with the means of subsistence, and if increasing to excess, finds an outlet in emigration, we fondly hope that the threatening evil may be averted from this empire. Manchuria presents a still larger field for Chinese colonists, they may also find uncultivated lands on the western frontiers, and may even send colonies to the west coast of America. It is very obvious, that this great mass of mankind is near a grand crisis. The world has changed, without their partaking in those changes, and it will be finally their turn to yield to the common impulse given from the west. If a handful of barbarians from the desert, could change the face of the country, should the enlightened spirit of enterprise, which now pervades Europe, remain dormant on its approach to the Chinese frontiers? We should regret if so many millions got into a state of fermentation, for the consequences would be awful; but if they do not advance with the world, they will sooner or later fall a sacrifice to their stubbornness.

Intelligent Chinese in reading this paper might perhaps quote a passage of their sages, and leave matters to proceed in their natural course, whilst they with all their countrymen persevered in the beaten track. Such is also the maxim of the government; nothing influences it but rare necessity. Time is on the wing with its revolutions, but they do not heed this flighty companion, until it is too late to keep pace with him.

SUMMARY.

NEW YORK CITY has a greater population than either of the States of Rhode Island, Delaware, Mississippi, Louisiana, Illinois, or Missouri.

Defence of New Orleans.—The steamboat *Henry Clay* passed down the river, opposite Natchez, on the 5th ult., with fifty tons of cannon balls, bound to New Orleans. A hundred tons of cannon have been ordered from the Pittsburg foundry for the same port—at least so says the Natchez Courier.

NEW CATHOLIC CONVERT.—The Church of Rome has appropriated \$60,000 for the establishment of a Catholic Convent, at Bertrand, Michigan.

Meeting of Wool Growers.—A meeting of a number of the wool growers of the County of Franklin was held at Shelburne Falls, on the 27 ult. A corresponding committee of eleven members was appointed, who were requested to ascertain the number of fleeces raised for the market in their respective towns, and to report at an adjourned meeting on the 20th of May. The Franklin Mercury states, that the proceedings of the meeting are preparatory to the establishment of a general wool market, to be held in some central place in the wool growing district.—[Boston Daily Advertiser.]

Another Steamboat sunk.—The Steamboat *Sheldon Thompson* was discovered about daylight this morning, sunk at her moorings near the south bank of Buffalo Creek, opposite the Storehouse of J. Mayhew & Co. She lies with the principal part of her main deck under water. No satisfactory cause has been assigned for this fresh disaster.—[Buffalo Com. Adv.]

[From *Tait's Magazine*.]  
**Private History of the London Newspaper Press.**

"If I live to return to London, I will tear the mask off these men, and show the public what sort of persons they are who thus govern the world under the mysterious appellation of 'We.'"  
 —[Speech of D. O'Connell, Esq., at Dublin, November.]

Mr. O'Connell, you are right. It is due to justice, to honor, to liberty, and to the magnanimous character of this nation, that these men should be unmasked. When so vast an influence is exercised by the Press, it is merciless that the mask should be worn: the most distinguished of our public men, themselves unprotected by the vizor, have thus fallen by mysterious hands—stabbed in the back by men who fight upon the 'vantage ground.' As circumstances have given us an extensive knowledge of the *personell* of the Press, we are willing to lend a passing hand in this good cause—thus doing for you and for the world, what neither you nor the world, without such assistance, can have the means of doing for yourselves.

The order to be observed, in our account of the Newspaper Press, is evidently to examine its divisions as they principally appear before the public eye. These are, *first*, the Morning Daily Newspapers; *second*, the Evening Papers; and *third*, the interminable varieties of the Weekly Press.

Accordingly, we proceed to raise the curtain upon the operators at the morning newspapers, commencing with that monarch of periodical literature—the all powerful *Times*.

The *Times* is a joint-stock company. It is held in twenty-four shares, which, in the time of the late Mr. Walter—the father of the present honorable member for Berkshire—were sold at the low rate of £100 per share. Through the exertions of that talented, high minded, and much-persecuted man, and the continued exertions and talent displayed by his son, this once insignificant concern has risen to its present extraordinary height of prosperity and power in the political world. It is now valued at the rate of £20,000 per share. Of the number of shares, six, or two-thirds of the whole, are the property of Mr. Walter himself—he deriving from his interest in the *Times* an income of more than £20,000 per annum—and this continually on the increase. For many years he was the managing proprietor—receiving an additional allowance of £2,000 per annum; but since the acquisition of his very enormous fortune, he has retired from Printing-House Square, and set up in the capacity of a country gentleman. He now, in no way whatever, interferes in the management of the *Times*.

The great gun of the establishment is now a Mr. Sterling. This gentleman was a captain in the army, and served in the Peninsular War. He is well known to the Duke of Wellington; and though no longer connected with the service, he yet continues to reside at Knightsbridge, opposite the horse barracks, and in the constant society of military men. He is the writer of the principal leading matter in the *Times*—all the "thunder" of that journal having, for now a number of years, proceeded from his pen. He first introduced himself to the concern by sending in a series of letters under the signature of "Vetus," the brilliancy of thought of which procured him an engagement upon terms which have been continually increasing to his present great salary of £1500 per year. Mr. Sterling has, however, no connection with the general business of the establishment, receiving that large income only for sending in from his own side the principal leader of the day. He is possessed of the most rapid and extraordinary powers of composition—sometimes producing in a single hour a full column of matter—compared to which nothing certainly has been seen in the political literature of England since the days of Swift. It is mere style however, for which this gentleman is distinguished; for, in the impetuosity and fire of his mind, political principles are deserted, returned to, and deserted again, with all that rapidity which gives so strong a character for inconsistency to the politics of the *Times*. This has often been felt by the proprietors; but so military are his de-

portment, habits, and political views, and so proud and unmanageable the temper of the man, that they are compelled to bear much upon this head, for the influence derived from the power and splendor of his style. Thus does Mr. Sterling carry over the *Times* to which camp he will. The present support of the government of the Duke of Wellington is entirely attributed to him. It is not asserted, however, that there is any thing corrupt in his motives—for Mr. Sterling is a man who would neither brook the control nor touch the mercenary gold of the mightiest monarch on the globe. The public may rest assured that he never will be enslaved to any party whatsoever, nor part with the power to dash into ten thousand pieces all who dare to prove disobedient to his will. Thus, in his rage at being baffled in his efforts to prevent the passing of the Poor-Law Bill, he has mercilessly malleted out the brains of the fallen tumbler of Vauxhall. The somewhat brutal attacks upon Mr. O'Connell respecting his rent—an affair altogether of a private nature between himself and those who choose to retain him in the service of his country; the scorn heaped upon that invaluable public servant, whom he designates as a "Mr. Joseph Hume;" the abuse of that accomplished politician, "his apprentice Roebuck," who presumed, contrary to the will of Mr. Sterling, to prevent a contemptible little Tory from becoming the representative for Bath; all the abuse of the "dirty Radicals," the "Kensington butcher," and the "Brummenham Hampden," proceeds from the pen of this Man in the Iron Mask. So great his power for evil or for good, and so savage is the use which he latterly has made of its abilities, that it really is high time that the people of England should know something of the profession and temper of a man, who thus, from his house at Knightsbridge, can fling down, as he would make-believe, Ministers of State, and make and mar whom he will. Let us hope that he will become more moderate now that he is known, and that these lines will be felt as a salutary hook in the nose of this leviathan of all the waters of the political world.

Next in importance as manager, or what is termed "the responsible editor" of the *Times*, is a gentleman named Barnes. The thunder has long been wrongfully attributed to him. He seldom, indeed, produces original matter of any kind—and then principally upon subjects of literature and the fine arts. He is an excellent linguist, and a very learned and accomplished man. He is also an indefatigable man of business, and, by night and by day, none can labor harder at the wheel. His salary is 1000*l.* a year, and he is now the possessor of one-half of a twenty-fourth share in the concern. Possessed of a well-ordered and very comprehensive mind, this gentleman carries on, with infinite ability, the whole machinery of the vast establishment of Printing-House Square. Whether in the appointment of correspondents abroad, or in the selection of the corps of reporters and others, who in numbers are supported from the profuse and well directed expenditure of the establishment, the discernment of Mr. Barnes is seen in every number of the *Times*. He exacts the most implicit obedience to his will; and, excepting the mighty Mr. Sterling, all bow down to Mr. Barnes. In politics his views are favorable to liberty—he feels the dignity of his post, despises all attempts to draw him from his own course—has no disposition abuse his power, and is, in every respect, a fair and honorable man. Therefore we advise him to live further from Printing-House Square than his present house in the borough; and thus, taking more pedestrian exercise, endanger not himself, from huge overgrowth of body and from over exertion of the mind—to that kind of dissolution—which comes "as butcher sells an ox."

The division of the *Times* called "the city article," is written by Mr. Alsager, a gentleman in Birch Lane. He has the large salary of £800 per annum, which he, indeed, very amply deserves. Mr. Alsager is possessed of the most comprehensive knowledge of the principles of commerce & finance, through which he has rendered important services to his country through the columns of the *Times*, and also, by well directed speculations, procured a considerable fortune for himself. His opinions are of great weight

amongst the monetary bodies in the city, and many a tremendous blunder his warnings have prevented amongst the men who, seated in a parlor in Threadneedle street, have the keeping of the welfare of the millions of the greatest empire on the earth. Were things well ordered in this commercial community, such men as Mr. Alsager would become Chancellors of the Exchequer and the like. Sheep-feeding Lords make sad slaughter in finance.

Mr. Bacon is the sub-editor of the *Times*; he and Mr. Murray write well and in a smooth style. Mr. Walters himself has not force enough for the *Times*; and, knowing that Mr. Barnes has a decided objection to his matter, he has long had too much judgment to attempt any thing of the kind. The productions of Mr. Sterling have been frequently attributed to Lord Brougham. Every possible precaution is taken to conceal this Mr. Sterling; and a reporter who wishes to remain upon the *Times*, must be at a considerable distance from any third person, and look very carefully round all points of the compass, before he will venture even to mention his very name. It is death without benefit of clergy. Altogether, there is no newspaper establishment in the world which can bear the shadow of a comparison with this; and notwithstanding the armies of enemies raised up by the occasional indiscretions of Mr. Sterling, there cannot be a doubt that the *Times*\* will very long continue to maintain a considerable share of power in the political world.

Next in antiquity, and till recently, in political consequence, comes the memorable *Morning Chronicle*. All remember this newspaper in the high and palmy days of the illustrious Mr. Perry. Upon the death of that gentleman, the *Morning Chronicle* was sold to Mr. Clements of the Strand, for the sum of £30,000, a price not certainly too large to a person of the capital and ability of mind to grapple with such a speculation. The new purchaser was, unfortunately, not possessed of either of these requisites to success in this very perilous attempt, and his paper maker very soon obtained an extensive mortgage upon the copy right of the paper. Thus crippled in his resources, the great expenditure required for foreign correspondence, and for first-rate talent in reporting from the Houses of Parliament, and the Police Offices, and the Courts of Law, was nowhere to be found. Then did the *Chronicle* fall fast into the rear. Not only was the foreign correspondence invariably copied from the *Times* and the *Herald* of the preceding day, but the expenses of the establishment were curtailed by the use of types of double the ordinary size, with straggling intervals called "windows," and other expedients for saving a few daily shillings of expense. Thus dwindled away the circulation of this once celebrated paper; and, latterly, its sale did not amount to more than about two thousand copies per day. Under these circumstances, Mr. Clements, in January last, disposed of his interest in the *Morning Chronicle* for the sum of £17,000, to Messrs. Grote the banker, Easthope the stock-jobber, and Joshua Parkes, the great Birmingham Whig. But even these gentlemen cannot be much flattered upon their present knowledge of the very difficult mysteries of the newspaper trade. The foreign correspondence is certainly improved, and, from the important points of Paris and Madrid, the *Chronicle* is amongst the earliest in the field; but still the windows remain open in the type, and there is not more than two-thirds of the quantity of matter which appears in the *Times*. But more injurious by far is the interpolation of the writing of some of the proprietors themselves in the columns of the *Chronicle*. This is a most fatal mistake. How many fortunes have been melted into thin air through this most expensive of all the follies of the vain! Though Mr. Parkes should write himself up into the Cabinet of the Whigs, yet not then will he find himself repaid for all the thousands he will squander on the way. Men follow not, in these days, the leaders whose battle is not for the liberties of mankind, but for the high places for themselves. The philosophic and invaluable Mr. Black should here be allowed, without let or molestation, to expound to the world his own

\* The errors of the *Times* have, of late, got far beyond indiscretions.

most masterly views upon politics and life. He is the Securus of the age, and ought not to be superseded by babblers. Upon public grounds we take the liberty of saying these things, because it is the absence of all power of competition which enables the giant of the Times to drive back, and to scorn and defy the advancing spirit of the age. There never was such an opportunity as the apogee of the Times presents to the advance of the Chronicle.

The *Morning News* has been built upon the ruins of the *Guardian* and *Public Ledger*, which it is fast following to the tomb.

The *Morning Post* is well known upon the Conservative side. It was the property of the Messrs. Byrnes, one of whom, dying of the cholera in the course of a few hours in the year 1833, bequeathed the Post to be sold, for the sum of £34,000, to the same elephant, and others of his party. The circulation is small, but, going much into the aristocratic circles, the advertisements are charged at a high price, and form a profitable return. Mr. Watson is the writer of the political articles, which are rabid, and therefore lose their effect.

Morning is now over, and we pass to the doings of the Evening.

Of the evening papers, the *Globe* has been the most conspicuous since the advent of the Whig administration. It is edited by Mr. Gorton, the compiler of a Biographical Dictionary, and other very fair works. This gentleman has, however, been a mere cipher for the last four years, the political articles having come regularly and daily from the offices of Lord Palmerston and Melbourne. It is called "Cupid's Album," because it is written by Lord Palmerston, and Lord Palmerston is called Cupid, because he kills ladies with his gold chain. Should the course of Cupid not again run smooth, the *Globe* will—but we will not prophesy its fate till we have further proved its new character.

The *Courier* is a joint-stock company, the shares twenty-four, and held by a diversity of persons. Political principle it has absolutely none, and of all the papers that ever walked the streets, this has probably been the worst. Amongst others who write editorial articles for its columns, is no less a personage than Louis Philippe, the King of the Barricades. Thus, if the reader will turn to the file of the *Courier* of the date of Thursday, March 29, 1833, he will there see, in the shape of an editorial article, the defence, by himself, of the King of the French—and certainly a very satisfactory defence—upon the charge of ingratitude towards his Minister Ladite, in suffering his property to be sold. For the last twelve months the *Courier* has been under the editorship of Mr. James Stuart, a Scotch gentleman of talent, and the author of a popular work of travels in the United States of America. This gentleman was before the public some years since, in consequence of his duel with Sir Alexander Boscwell. Why we mention the private affairs of Mr. Stuart, which is done with the greatest respect, is to undeceive the public as to the present standing, property, and influence of the new *Courier*; for it is given out, and out of Scotland, very extensively believed, that Mr. Stuart has merely become editor of the *Courier*, for the purpose of mental occupation, and to drive away his cares consequent upon the affair alluded to above. So honorable, wealthy, and dignified a person, it is said, would never have accepted an appointment as the editor of a newspaper, without the most perfect liberty of action, upon principles of his own; and, therefore, the independence of the *Courier* is now undoubted and complete. These assertions may be true, and the public may probably possess the guarantee for the independence of the *Courier*, but that is no reason why we do not inform our readers that Mr. Stuart no longer is possessed of any property whatever, his estate in Scotland, and everything possessed by him in the world, having been swept away by reason of indiscreet speculations at the period of the panic. The public has an undoubted right to be informed that the person who states "that Mr. O'Connell wheedles and cheats the peasantry of Ireland out of two-pence and pence," is quite as likely to be commanded by his employers to say those things, as any other person whose subsistence depends upon his pen. The *Courier*

lately perpetrated itself in the dirt at the feet of the Duke of Wellington. His Grace did not deign to pick it up. It is trying to recover from the false alarm—but the mud sticks.

The *Sun* is an evening paper of moderate notoriety. Mr. Marde Young is the proprietor of this luminary. He also found favor with the Whigs, and he still fights well in their behalf.

The *Standard* is owned by Mr. Baldwin and edited by Mr. Gifford and the well known Maginn. This paper is another instance of the power of mere style; for it has fought its way to a large circulation under all the disadvantages of a long name.

Finally, we shall glance at that very important division of the metropolitan press, the Sunday newspapers.

First, then, is the colossus of weekly literature, the *Dispatch*. It is the property of Mr. Harmer of Heston-garden, who has made many thousands of money by its success—previous to which he possessed not much. Its principal writer is a Mr. Williams, who produces the first or principal leading article, and the letter under the signature of Publicola. This gentleman was formerly a Lieutenant in the Navy, in which capacity he acquired his view of the former tyrannical horrors of our vessels of war, the remembrance of which has given such a tremendous power to his pen. His father was an American loyalist, and related to General Hayne, the late very distinguished Governor of South Carolina. Mr. Williams has also been the editor of an edition of Thompson's Seasons, and of Milton's Paradise Lost, and the author of an original and powerful work, called "The Tales of Old Mr. Jefferson," books which the public ought to buy, in honor of one of the noblest warriors that ever yet appeared in the cause of the liberties of man.

Superior in brilliancy of style, and little inferior to the *Dispatch* in fixedness of purpose, comes that bright gem of political literature, the *Spectator* newspaper. Great sums of money have been lost, and certainly very honorably lost. Mr. Day, formerly the blacking-maker of Holborn, has had much connection with this paper, expending much liberally—because with little prospect of remuneration—a portion of his fortune in the support of this bright and liberal publication. The price of the *Spectator* is the only stumbling block to its triumphant success. We, therefore, suggest that, by a diminution of the size of the paper, and the partial discontinuance of its refined productions in literature, theatricals, and the fine arts, the *Spectator* might be conveniently sold at the ordinary price. With this change it would rise to a circulation of ten thousand in a single month. Its editor is a Scottish gentleman—Kintont by name.

There is also the *Sunday Times*, a pleasant and inoffensive print. It goes chiefly into "families," and, therefore, pretends not to any particular political decision. This paper was founded by Mr. D. W. Harvey; whose energetic writings advanced it to the large circulation of ten thousand copies per week. That gentleman then sold it for the sum of £7000 in money, and an annuity of £400 per annum, which he enjoys at the present time. Its circulation is good, but has much gone down. Mr. Gaspary is the editor and partly the proprietor of the *Sunday Times*.

The *John Bull* is still edited by Mr. Theodore Hook. This paper was established by the Government—the expenses having been paid by the Treasury for the first six weeks. Owing to the assistance of Mr. Croker, and style of Mr. Hook, further assistance was not required—the paper having been brought to be a valuable property in that unexampled short period of time. Owing to the change in the health of Mr. Hook, the *John Bull* is now much less prosperous than in the early part of its career. This gentleman was seized with apoplexy at his house at Putney, and lay for a considerable time in a very debilitated state. Since that period, both in his political writings and in his literary productions, there has been a corresponding diminution in the vigor of his mind. Mr. Hook has recently sold one of his remaining quarter shares in the *John Bull* for the sum of £4000.

Into the lower region of the press—the slaves wherein dwell the Aps, and the other children of

John Bull—at present at least we will not go to. The *True Sun*, the *Morning Advertiser*, and the *Examiner*—all honest men laboring in the good cause—we also reserve for the present.

#### RAILWAY IRON.

25 tons of 1 inch by 1 inch, Flat Bars in lengths of 300 do. 3 1/2 do. do. 14 to 16 feet, counter sunk holes, ends cut at an angle of 45 degrees, with sliding plates and nails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins. Wrought Iron Rims of 20, 22, and 26 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels. Axles of 2 1/2, 3, 3 1/2, 4, and 4 1/2 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & O. BALSTON, 8 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d77maw

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscribers' Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as in England, where the subscriber obtained a Patent), are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersunk heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are furnished with Spikes made at the above named factory—for which purpose they are found invaluable, as their introduction in more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by J. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy, J. J. Brewer, 222 Water street, New York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; DeGrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing as to keep pace with the daily increasing demand for his Spikes. H. BURDEN.

#### MILL DAM FOUNDRY FOR SALE.

The Proprietors of the Mill Dam Foundry offer for sale or lease their well known establishment, situated one mile from Boston. The improvements consist of:

No. 1. Boiler House, 30 feet by 20 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. Blacksmith's Shop, 30 feet by 20, fitted with cranes for heavy work.

No. 3. Locomotive House, 54 feet by 25, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with shingles, 100 feet by 60, containing two water-wheels, equal to 60 horse power; Machine Shop, fitted with lathes, &c.; Pattern Shop.

The above establishment being on tide water, presents greater advantages for some kinds of business than any other in the United States. Coal and iron can be conveyed from vessels in the harbor of Boston, to the wharf in front of the Foundry, at 15 to 20 cents per ton. Some of the largest jobs of iron work have been completed at this establishment; among others, the great chain and lift pumps for freeing the Dry Dock at the Navy Yard and Charlestown.

The situation for Railroad work is excellent, being in the angle formed by the crossing of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at their works. With the Pattern and Machinery now in the premises, 12 Locomotives and as many tenders, besides a great quantity of cars and waggon, could be made per annum.

For terms, apply to THOMAS J. BOULEY, Treasurer, &c., Boston, or to ROBERT BALSTON, Jr., Philadelphia.

Boston, Dec. 20, 1831.

**RAILROAD JOURNAL AND ADVOCATE OF  
INTERNAL IMPROVEMENTS.**

This work is published once a week, in quarto form, of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, IN ADVANCE. Previous volumes same price; full set of four volumes, \$12.

**RAILROAD AND CANAL MAP,**

on, on  
two,  
a con-  
of, or  
of let-  
out up  
cover,  
entry.

R O P  
J.

This work has completed 4 volumes, or two years. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, IN ADVANCE. Previous volumes \$1.50 each.

**THE APPRENTICE'S COMPANION—**

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—was published at the office of the Mechanics' Magazine, No. 25 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY-TWO for \$10. D. K. M.

**NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.**

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Volumes 6 and 7, or 1 and 2, new series, \$3 per volume.

**QUARTERLY JOURNAL OF AGRICULTURE, MECHANICS, AND MANUFACTURES.**

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$5, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 220 pages.

These works may all, or either of them, be had of S. Hydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,  
25 Wall street, New-York.

**GOLD REGION OF THE UNITED STATES.**

Now in press and will be published in a few days the first of a series of numbers, giving a minute and particular description of the entire Gold Region of the United States.

Each number will be accompanied by a Map, on which will be laid down, and numbered, with owner's name, in the order of discovery, of every Gold Mine within the district of which the number treats, so that any person can ascertain the location, owner's name, and condition, as late as January 1, 1835, of every Gold Mine, or place where gold has been discovered in the United States.

The first number, which will be issued by the 20th of April, will give the Gold region of North Carolina; together with a very interesting Essay, upon the Gold region of the United States, from the transactions of the Geological Society of Pennsylvania, by James Dickson, Esq., F. G. S. of London, C. M. G. S. of Pennsylvania, &c. &c.—With other interesting and important information in relation to the supply and consumption of Gold.

The information and maps are by a scientific gentleman, who has visited personally what he describes.

No. 2, including the States of Virginia and Maryland, will be published by the first, or during the month of June.

No. 3, giving Pennsylvania, New Jersey and New York, by the first of August. And the succeeding numbers, 4 and 5, which will probably complete the series, by the first of January next.

The terms will be \$1 per number, or \$5 for the Series.—Subscriptions addressed to D. K. MINOR, or to the publishers, T. & C. WOOD.

No. 7 Wall street.

Gentlemen who may have particulars, or details, of present condition of mines in North Carolina, will oblige me by communicating the same, that the work may be as complete as possible. D. K. MINOR.

**NOTICE.**

The Board of Directors of the NEW YORK AND ELIZABETH RAILROAD COMPANY, believing that the interests of this City demand that the construction of their Railway should be immediately commenced, and having resolved, with undiminished confidence in the merits and early productiveness of the undertaking, to proceed to their operations without delay, hereby give Notice, that in order to provide means adequate to the completion of a single track of the Railway over an extended and most important portion of the route, subscriptions for Two Millions of the capital stock will be received at their Office, No. 29 Wall street, on the 15th day of April next, and the two succeeding days. Five Dollars on each share is required to be paid at the time of subscription.

It is to be understood that no further issue of Stock will be made within two years, and that it is the object of the Company, before the expiration of that period, with this and the former subscription, to put such portions of their Road in operation, as will, they confidently believe, yield a profitable return on the outlay thereof.

New York, 30th March, 1835.

By order of the Board.

JAMES G. KING,  
JOHN G. COSTER,  
PETER G. STUYVESANT,  
MICHAEL BURNHAM,  
KLEAZAR LORD,  
GOULD HOYT,  
STEPHEN WHITNEY,

Committees to receive Subscriptions.

**LAFAYETTE.**

The Eulogy by JOHN GUNTER ADAMS, on the Life and Services of this Benefactor of Mankind; on a beautiful paper and type; with a spirited medallion portrait in lithography. Is just published and for sale by D. K. MINOR, 35 Wall st.

**RAILROAD CASTINGS.**

MINTY & WARD, Proprietors of the Albany Eagle & Furnace and Machine Shop, will make to order car wheels, chairs and keases, and every other description of castings required for railroads. R-ly 1014

**PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.**

Railroad Spikes of every description required, made at the Albany Spike Factory. Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. Sep. 18-1y

**STEPHENSON,**

Builder of a superior style of Passenger Cars for Railroads.

No. 264 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J25 1f

**RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.**

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to. Also, CAR SPRINGS. Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR.

**NOTICE TO MANUFACTURERS.**

SIMON FAIRMAN, of the village of Landingburgh, in the county of Kennebec, and state of New-York, has invented and put in operation a Machine for making Wrought Nails with square points. This machine will make about sixty 6d nails, and about forty 10d nails in a minute, and in the same proportion larger sizes, even to spikes for shingles. The nails are hammered and come from the machine completely heated to redness, that its capacity for being clenched is good and sure. One horse power is sufficient to drive one machine, and may easily be applied where such power for driving machinery is in operation. Said Fairman will make, vend and warrant machines as above, to any persons who may apply for them as soon as they may be made, and on the most reasonable terms. He also desires to sell one half of his patent right for the use of said machines throughout the United States. Any person desiring further information, or to purchase, will please to call at the machine shop of Mr. John Hamphrey, in the village of Landingburgh. August 18, 1833. AD 17 R M A P

**SURVEYORS' INSTRUMENTS.**

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by E. & G. W. BLUNT, 154 Water street, corner of Maiden lane. J21 1f

**SURVEYING AND ENGINEERING INSTRUMENTS.**

The subscriber manufactures all kinds of instruments in his profession, warranted equal, if not superior in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes. W. M. J. Y. UNG.

Mathematical Instrument Maker, No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1835.

In reply to the inquiries respecting the instruments manufactured by me, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of the make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that the patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sight, leaves the engineer scarcely anything to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLEY, Sup't of Construction of Baltimore and Ohio Railroad. Philadelphia, February, 1835.

Having for the last two years made constant use of Mr. Young's Patent Improved Compass, I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

K. H. GILL, Civil Engineer.

German town, February, 1835.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for the purpose.

HENRY R. CAMPBELL, Eng. Philad. Colonel and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, APRIL 18, 1835.

We lay before our readers a very inter-  
esting letter from an American gentleman  
in London, upon the subject of rapid travel-  
ing on canals, and of steam carriages on  
common roads. The writer will please ac-  
cept our thanks for this, and other favors  
past; and permit our readers to thank him  
also, *in advance*, for other letters which  
they anticipate from him through the me-  
dium of the Journal.

A continuation of Mr. Mills' Report of  
his survey of the Rochester and Olean Ca-  
nal will be found in this—it will be conclu-  
ded in the next number.

☞ The books of the Company for a  
further subscription to the stock of the  
New-York and Erie Railroad, were opened  
on Wednesday. On the first day over  
\$600,000 were subscribed, and on closing  
them it was found that the amount of sub-  
scription was over a million; which, with  
the \$1,000,000 before subscribed, will en-  
able them to commence operations at once,  
and to complete about 200 miles of the  
road. This will beyond question secure  
the construction of the road, notwithstand-  
ing the opposition of gentlemen in the more  
favored section of the State.

**Charleston Railroad.**—The southern Patriot  
says, the increasing travel and transportation on  
the Charleston Railroad, since the commence-  
ment of the present year, have exceeded the ex-  
pectations of every one. The actual receipts, as  
is well observed, furnish the best evidence of the  
prosperity, and by comparison, of the increasing  
business of the road. These receipts are given  
for the first three months of the current year, and  
the corresponding period of last year, as follows :

1834.	1835.
January, \$4,239	January, \$13,290
February, 8,174	February, 14,875
March, 11,988	March, 17,458
<b>\$24,391</b>	<b>\$45,624</b>

This shows a great increase, indeed; the re-  
ceipts nearly doubling, in the course of a single  
year. The number of passengers who travelled  
the road, during the year ending on the 1st of  
April, is stated 29,240.

Thus it is on the Charleston Road, and thus it  
will be on the New-York and Erie Road. The  
increase of business from improved facilities is  
not generally appreciated.

[From the Baltimore American.]

**WASHINGTON RAILROAD.**—We learn that a de-  
finite and entirely satisfactory arrangement has  
been agreed upon between the Corporation of  
Washington and the Baltimore & Ohio Railroad  
Company in relation to the location of the rail-  
way within that city. A most liberal and accom-  
modating spirit, we are informed, has been mani-  
fested by the city authorities there towards the  
Company, and under the provisions of the ordi-  
nance just passed, the Railroad Company are au-  
thorized to use steam as a moving power to the  
point desired by them, near the western foot  
of Capitol Hill, from which place the road will  
be continued across Pennsylvania avenue to the  
Canal.

The satisfactory adjustment of this matter  
leaves the Co. from free any obstacle in the way  
of their immediate completion of the work, and  
the entire line both for graduation and masonry  
is already under contract, under a confident ex-  
pectation that within three months the road will  
be open for travel.

The accomplishment of this work will bring  
the two cities into a very intimate intercourse, re-  
ciprocally beneficial. The trip will no doubt be  
regularly performed within two hours, and will  
afford a most delightful excursion—hundreds will  
daily avail of it, and we doubt but that the  
commercial as well as social relations of both  
cities will be greatly promoted. Indeed the  
whole Union has a deep interest in the work;  
and we venture to predict that the day is not dis-  
tant when travellers leaving Washington in the  
morning will dine in Philadelphia, and arrive the  
same evening in New York.

## Swift Passage-Boats on Canals, and Steam Carriages on Common Roads.

London, February 6, 1835.

To the Editor of the Railroad Journal.

SIR,—I observe you have published in  
your Journal of the 12th. December last  
my letter to you relative to the locomo-  
tives plying on the common turnpike—the  
“City road”—from the neighborhood  
of the Bank of England to Paddington.  
Since I addressed you, I have been on a  
tour to the north, as far as Dundee, in  
Scotland, and visited most of the rail-  
ways and manufactories of locomotive  
engines of the island.

When at Glasgow I visited the “Pais-  
ley” and the “Forth and Clyde” canals;  
and as our country is very much interest-  
ed in canal navigation, some memoranda  
relative to the *swift passage boats* on those  
two canals may not be uninteresting to  
your readers.

First, of the “Paisley Canal,” which  
has been the longest known, and is still  
most successful as regards quick travel-  
ling. This canal commences at Glas-  
gow, and goes through Paisley (8 miles  
distant) to Johnston, where it terminates;  
12 miles long; no lock in the whole dis-  
tance. The boats are of iron, of one  
sixteenth of an inch thick, 70 feet long,  
5 ft. 9 in. broad, and weigh 16 cwt. 14 lbs.  
This is the weight of the iron part alone.  
The total weight of the boat, including  
the wood work, (the cabins are of this  
material,) fixtures, &c. is 33 cwt.; and  
with 100 passengers, draws 19 inches aft  
and 18 inches forward. Two horses  
draw the boat in stages of four miles each;  
the pair of horses go only 12 miles per  
diem. There are four boats, which make  
six journeys each, or twenty-four jour-  
neys for the whole, each day. These  
boats have been running four years.  
They are generally full. They meet the  
greatest encouragement, and are very  
profitable to the proprietors, notwithstand-  
ing the fare is so very moderate. The  
charge is 6 pence, in the after cab-  
in, and 9 pence in the forward, to Pais-  
ley, 8 miles; to Johnston, 12 miles, the

charge is 9 pence in the after cabin, and 12 pence in the forward cabin. The time usually employed between Glasgow and Paisley is 50 minutes, or  $9\frac{1}{4}$  miles per hour. This is the narrowest canal I ever saw, generally 30 feet wide and 5 feet deep. The captains of the boats on board of which I travelled, told me that on a narrow canal, such as this, the horses can pull a boat easier, *when travelling rapidly*, than on one of greater section. This, paradoxical as it may appear, is verified by the fact, that on the "Forth and Clyde" canal, which is of 9 feet depth, and 68 feet breadth, the boats, which are of nearly the same dimensions (68 feet long, and  $5\frac{1}{2}$  feet broad,) as those on the Paisley canal, are drawn by *three* horses, with 70 passengers on board, and yet travel at about the same velocity as on the narrower and shallower canal. I asked these captains, and also a civil engineer of some eminence, whom I met on board, returning from Johnston, how they could account for this circumstance. Their reply was as follows: On a narrow canal, say 30 or 40 feet wide, the boat passing swiftly through the water, throws the wave against the shore, which being thrown back again against the boat, raises it up, and thus propels it. The wave strikes the boat about two thirds of its length from the bow. But if the canal were much wider, the boat would pass by before the *reflected* wave could reach the boat, and thus give it aid. I give this explanation nearly in the words of these captains, and am responsible only for the correctness of the report of what they told me. I hope this will meet the eye of our distinguished countryman, Gen. C. F. Mercer, Chairman of the Committee of Internal Improvements in the H. of R., who advocates with so much ability *broad and deep* canals for transportation, as far more economical than narrow canals. I will now finish what I have to say respecting the fast travelling on the "Forth and Clyde" canal.

This canal, as I have said above, is 68 feet broad by 9 feet deep, and the iron boats are 68 feet long and  $5\frac{1}{2}$  feet broad, and when light draw 8 inches water, but with 70 passengers draw 20 inches; this is when in a state of rest,—when in rapid motion they draw less. There are 3 horses employed to each boat, and the passengers who get into the boats at Port Dundas (Glasgow) are set down at Port Hopetown (Edinburgh) in  $6\frac{1}{4}$  hours, a distance of 56 miles, or nearly 9 miles per hour. It is necessary to explain to you that the passengers go only a part of the distance on the "Forth and Clyde" canal. They start from Port Dundas and go to Port Downie, (the commencement of the "Union Canal,") a distance of  $24\frac{1}{2}$  miles, which includes 4 locks. In the next half mile are *eleven* locks, which are avoided by the passengers being conveyed in omnibuses to boats in the "Union Canal," which carry them on a level of 31 miles to Port Hopetown (Edinburgh). I regret that I did not take a memorandum of the cost of these iron

boats, which are light and beautiful vessels, and being fearful of making a mistake I do not quote from memory. On the Lancaster, Carlisle, and Kendal canals, there are rapid boats, but not having travelled by them I do not give you any details. But if any of your readers feel an interest in the above remarks, and wish further information, I can with facility procure it, and will with pleasure communicate it to you.

Since my return from the north I have called on Mr. Hancock, in company with Mr. T., one of the engineers of the Boston and Providence Railway. We found that for the last two months the "Era" and the "Autopsy" have discontinued running, owing to the absence of Mr. Hancock in Ireland, whither he went with the "Era," for the purpose of ascertaining if he could profitably introduce locomotives on the roads of that country. He is now returned to London, and will, I am informed, recommence running these two engines on the metropolitan roads in a few days. Mr. T. and I also went to see Mr. Russell's steam carriage, recently arrived from Glasgow, which will in a few days ply regularly, in conjunction with others of this gentleman's make, between Hyde Park Corner, and Hammersmith (the commencement of the great western road out of London.) This carriage is by far the most tasteful of all the steam carriages I have seen. It is built exactly like the stage coaches of this country, except the dimensions are larger. The whole of the machinery is in the hind boot. The water and the coke are in a *tender*, or separate carriage on two wheels, behind the locomotive. This steam coach will carry six inside passengers sitting *vis-a-vis*, 14 outside on the roof, and six on the tender; total, 26 passengers. From the favorable terms in which I have heard Mr. Russell's engine spoken of, both here and in Glasgow, I feel a great curiosity to ride on it, and I will take advantage of the first opportunity to do so, and will report to you respecting it, as well as others which will no doubt be introduced as the spring advances. You may inquire, why did not Mr. R. remain in Glasgow? I will reply in nearly the words of the gentleman who shewed us this carriage. He said the prejudice against it was great, in consequence of the unfortunate accident by which 12 or 13 passengers were killed or wounded; that it was expedient to come to a distant part of the country. He told us, that for several months this engine plied between Glasgow and Paisley, and performed in a manner to give entire satisfaction; and in consequence, the stage coach proprietors and trustees of the road were alarmed lest this and others would gain so much in public estimation as to become regular coaches. They therefore resolved to drive it off, if possible. This they accomplished by *picking up* the turnpike, and putting fresh metal down in unusual and extraordinary quantities. Notwithstanding the road was made almost impassable, the engine was still continued, and plied regularly several

times each day for a whole month, and excited the admiration of all intelligent persons, that it *could* overcome such difficulties. It however was finally injured by being driven for so long a time over a *road so much worse than it was constructed for*, and one of the hind wheels getting into a hole (made by order of the turnpike proprietors), it broke, and the carriage tumbled to the ground; 4 or 5 persons were killed, and 8 or 9 others seriously maimed and wounded. But none of them were hurt from the explosion of the engine, or the escape of steam, but from being thrown with great violence against the rough, new mettled road—the same kind of injury as would be received from a common stage coach breaking one of its wheels when travelling rapidly. I am informed that an action is brought by the owners of the steam carriage, as well as by several of the survivors and the friends of the deceased, killed by this melancholy event, against the road company, for obstructing the King's highway, and causing the injury and death of a number of persons, besides loss of property. Sanguine hopes are entertained that the guilty will be severely punished.

I forgot to tell you above, that the swell on the two canals, caused by the quick passage of the boats, is very inconsiderable.

I am, very respectfully, your obedient servant,  
GERARD RALSTON.

P. S.—The demand for railway locomotives is very great. I am sending nine to different parts of the United States, and both Mr. Robert Stephenson and Mr. Bury have orders to give them full employment for several months to come.

*Report of Frederick C. Mills, Engineer, to the Honorable the Canal Commissioners of the State of New-York.*

(Continued from number 14.)

For the purpose of ascertaining the quality of stone, and the facility of procuring them, I examined the quarries within a reasonable distance of the canal. For the line from Genesee to Rochester, limestone will be used, and is found of a very superior quality near Avon Springs and at Caledonia. There is stone at Rochester which may be used in some parts of the work adjacent; but of an inferior character.

All the quarries from Mount Morris south, either on the Dansville side cut or in the vicinity of the main canal, are sand or grit stone varying in hue from pale blue to ash color. They are fine building stone, (of the kind) quarry easily, and in good shape for the construction of the mechanical work; they are abundant and generally convenient to the line, especially on that part of the route from Portageville to Olean.

It will be seen by referring to the detailed estimate of the different proposed kinds of locks, that the average cost of a composite lock of 10 feet lift will be \$3,700.79, and of a hammered stone lock \$5,193.98, making a difference in favor of the first description of lock of \$1,493.19.

The difference between these two modes of construction is small when it is borne in mind, that the former will require a thorough repair of all the wood work connected with the chamber, once in 8 or 9

## ADVOCATE OF INTERNAL IMPROVEMENTS.

years, which is rendered still more expensive on account of the season of the year at which it would be necessary to perform the work, in order to obstruct the navigation as little as possible. The estimates throughout the line are made upon the latter mode of construction, which I think it would be well to adopt, at least between Mount Morris and Rochester, where the stone is particularly suitable, and where the suspension of the navigation would be sensibly felt. On the other parts of the line it may be found advantageous to substitute the composite lock, as with the exception of a few quarries on Canadea creek and in that vicinity, the stone is not of so good a quality as that below for making permanent hammered work, coping or quoins.

### FEEDERS.

The question of supplying the summit of this canal, and the lower levels dependent upon it with water, is one of the most interesting and important, which now presents itself for consideration.

On referring to gauges taken by Judge Geddes in 1825, on the same summit, I was led to doubt, whether a quantity adequate to the demand could be obtained, and consequently devoted much time to a careful investigation of the subject.

From the best information I could obtain, a more favorable opportunity has not occurred for several years, of ascertaining the quantity of water which may at all times be relied upon, for the supply of the summit level, on account of the very low state of the water in all the streams at the time of gauging. For this purpose dams were thrown across the several streams, with apertures and sluices, in a form best calculated to concentrate and shape the volume of water for measurement.

The following statement shows the minimum flow of running water, that may be commanded for the summit, viz:

	Cubic feet in a minute.
Ischua creek, - - - - -	1,122.00
Lime lake, - - - - -	258.00
Fish lake, - - - - -	311.64
Beaver and Mud lakes, - - -	244.80
Black creek, - - - - -	33.56
Oil creek, - - - - -	36.00
Little Oil and Swamp creek, -	38.00
<b>Total, - - - - -</b>	<b>2,044.00</b>

To conduct this water to the summit 9 $\frac{1}{2}$  miles of artificial feeders will be required, viz:

For Ischua creek, - - -	2 miles 52 chains.
" Lime lake, - - -	1 " 39 "
" Beaver and Mud lakes, - - -	2 " 66 "
" Fish lake, - - -	2 " 27 "

Which, together with the requisite dams and bulkheads, are estimated to cost \$29,000.

The water from these lakes must be turned into Ischua creek, and occupy its channel to Ischua feeder, a distance of about 14 miles, through which it will be received into the summit level.

Lime, Beaver, Mud and Fish lakes, lie in the towns of Machias, Freedom and Farmersville, all within the compass of 7 miles.

Lime lake is 18 $\frac{1}{2}$  miles from the canal, and 156 feet above the summit level. Beaver lake is 209, Mud lake 218, and Fish lake 267 $\frac{1}{2}$  feet above the same point. The south end of Lime lake is separated from the Ischua, by a Tamerack swamp 1 $\frac{1}{2}$  miles in length, and rises on an average, 2 $\frac{1}{2}$  feet above the surface of the water in said lake. At the time of making the survey, I was informed that the water in this lake had

been raised from 2 to 3 feet above its ordinary level, by a dam at the outlet, and that it was the intention of the proprietors to raise it 4 feet more. This may be done at small expense, and by excavating a channel to the Ischua, not exceeding 8 feet in depth, the lake may be drawn down 7 feet.

On the outlet, near the above mentioned dam, a grist-mill is being built, estimated to cost \$5,000, and should the water of Lime lake be turned to the south, this mill will sustain an injury, and be a subject of claim for damages. The reservoir would average an area of 135 acres by 7 feet deep.

Fish lake is divided into two parts of unequal size and of different elevations; the upper and largest division is 6 feet above the other, and in the dry season has no discharge into the lower division, unless it be through a subterraneous passage.

Willard Law has a saw-mill at the outlet of the lower pond, and is building a dam 180 feet long, by which he designs raising the water so as to flow back into the upper pool 2 $\frac{1}{2}$  feet.

In order to use this lake as a reservoir, it is proposed to raise Mr. Law's dam 7 feet higher, which will give an area of 120 acres, from which 10 feet in depth may be drawn.

The outlet flows into Clear creek, a branch of Cattaraugus creek. Between Fish lake and Cattaraugus creek, there are 3 grist-mills, 3 saw-mills, and 2 card and clothing works, which in part receive their supply of water from this source, and should the water be used for a feeder or reservoir, claims for damages will ensue.

Mud lake west of Fish posed, the w drained 10 f plated surface nel not exce 27 miles in map, it will these lakes a natural channel, and unite with those of Beaver lake near its outlet, whence they will be conducted into one of the branches of the Ischua, by an artificial feeder of 2 miles and 66 chains in length. Mud and Beaver lakes cover 50 acres each, and may be conveniently raised 6 feet higher, which will add about 70 acres to their area = 170 acres. On the outlets of these lakes, there are a few saw-mills and other works of small note, which will sustain some injury. The surface of country drained by them, is estimated at 20 $\frac{1}{2}$  square miles. Their principal and most permanent sources of supply, especially in the dry seasons, is from springs.

It is difficult to determine with much precision, the extent of damage that may be sustained by diverting the waters of these lakes from their natural channels. They flow north into Cattaraugus creek, and should there be any want of water at the mills on that stream, it may not be improper to suppose, that claims for damages will be presented; the most depressed of these lakes, is about 1,072 feet above Lake Erie.

The following statement shows the capacity of the lakes, and other streams available on the summit level; and the quantity that may be held in reserve by damming the lakes to be used during the dry season, which from my investigations on that subject, I have reason to believe, rarely if ever exceeds 140 days, showing also how much may be drawn per minute

for the above time, and for the filtration and to the increased surface with the cost will perhaps, be as you in determining the feasibility of this plan of supplying the canal with water, as any thing I may say further on the subject.

Names of Feeders.	Area in acres.	Cubic ft. of water after deducting loss by evaporation, &c.
Lime lake,	130	208.00
Beaver and Mud,	100	151.80
Fish lake,	89	236.64
Ischua feeder,		652.00
Black creek,		33.56
Oil creek,		36.00
Little Oil and Swamp creeks,		38.00

**Total cubic feet per minute, 1,556.00**

Names of Lakes.	Cubic feet of water after deducting loss by evaporation & filtration.	Cubic ft. per minute to discharge the reserve water in 140 days.
Lime lake,	41,004,117	298.30
Beaver lake,	22,241,734	110.30
Mud "	19,348,302	98.00
Fish "	51,691,668	256.10

**Amount per feeders as above, 1,556.00**

**Total, 2,223.70**  
**Cost of feeders and reservoirs, \$4,825.38**

The summit level, pally dependent upon water, are together and (with the except where lining must be which this portion constructed, is of it making tight banks, the line extending through the deep cutting in the summit swamp very little, if any, waste of water will occur, except what is occasioned by evaporation.

It now remains to determine what quantity of water will be adequate to the demand in this portion of the canal.

John B. Jarvis, Esq., gives 487 cubic feet per minute per mile, as the probable quantity of water that will be required to supply the Chenango canal, from the summit level. This estimate is predicated upon a quantity sufficient to pass 20 boats each way every 24 hours, allowing 20 per cent. for waste from the locks, and 100 cubic feet per minute per mile for filtration and evaporation.

In referring to this subject in your annual report, to the Legislature in 1834, I find the Commissioners were apprehensive that the amount allowed for filtration and evaporation on the Chenango canal, would be found insufficient; but that they were "inclined to the opinion that with proper care in guarding against the waste of water, 100 cubic feet per mile per minute for leakage, filtration and evaporation would be a safe estimate for the western and middle sections of the Erie canal." If necessary I might go into detail on this subject, and state the results of a variety of experiments made in this and in other countries. Those, however, upon which much reliance may be placed with regard to our canals, have been principally made in the States of New-York, Pennsylvania and Ohio, and as those together with my own estimates and experience in this matter, only go to corroborate and confirm the opinion advanced by the Commissioners, I deem it sufficient to

mention, that from the knowledge I have of the materials composing the banks of the Erie canal, the soil through which this 30½ miles of the Rochester and Olean canal passes, will not suffer by comparison, and should the work be performed with proper care, I am fully of opinion that no more water will be required for leakage, drainage and evaporation per minute per mile, than was found necessary for the same purpose on the twenty miles of canal west of Rochester aqueduct, as gauged by Mr. Bates in 1824.

It results then, that by a careful construction of the work contemplated, the estimated 100 cubic feet per minute per mile, will be a safe allowance for filtration and evaporation.

Now assuming an average of 28 boats\* to pass each way from the summit every 24 hours, provision must be made for a maximum of 60 lockages of water per day, and as the locks which govern this question are 7 feet lift each, the quantity required will be 367½ c. feet; to this add 25 per cent. for waste from the locks, and we have 459 c. feet for lockage water per minute.

Hence it appears that the quantity of water requisite to supply the summit and south to Olean, and then north to Ketchum's, (where it is proposed to take in the Genesee river as a feeder,) is,

For filtration and evaporation  
30½ miles, . . . . . 3,025 c. ft.  
For lockage water per minute, . . . 459 "

Total, . . . . . 3,484 "  
The sources of running  
water as heretofore con-  
templated, . . . . . 2,044  
Deduct loss by filtration  
and evaporation in con-  
ducting said water on  
to summit, . . . . . 488

Deficiency, . . . . . 1,928 "

To make up this quantity it be-  
comes necessary to resort  
to reservoirs, three of which  
are artificial and four natu-  
ral ponds or lakes. The  
lakes will furnish per min-  
ute, (as seen in the preced-  
ing table,) . . . . . 667.70

1,260.30  
1,260.30 cubic feet per minute still re-  
main to be made up entirely from artificial  
reservoirs.

The subject of supplying canals from these sources has been treated on at large in relation to the Chenango canal, and presuming that I can present nothing new, or that would aid the Commissioners in determining the practicability of the plan, I will briefly state the result of my survey, the capacity of the reservoirs, and the plan upon which the estimate is made.

The Ischua creek reservoir is located 3 miles from the summit level, near the head of the feeder at Farewell's mill dam. The present dam is 4 feet high and 9 feet above the bottom of the canal. It now overflows about 15 acres, the principal part of which is covered with timber. The creek has an average fall of about 12 feet to the mile. The hills on either side are high and precipitous. The width of the valley at the dam is 14 chains, and for the length of the reservoir average 15 chains. By raising the

\* This is quadruple the number necessary to do the present business of the canal; but it has been thought proper to make provision for a large increase of trade.

mill dam 12 feet higher, the water will set back 1½ miles, covering an area of 180 acres. The soil is clayey, of an impervious character.

The road up the valley will be overflowed by the pond, making it necessary to build a new one along the side of the hill, for 20 chains in length.

An allowance must be made for damages to Farewell's saw-mill, which is supplied with water from this source.

This reservoir has a drainage into it of 65 square miles of country, and taking one-fifth of the down fall water, (36 inches,) as the quantity which will drain off, we have 1,098,825,760 cubic feet, a quantity more than sufficient to fill the reservoir eleven times.

I proposed building two reservoirs on Oil creek, which crosses the canal about 2 miles north of Cuba. At Cady's mill the valley bordering on the creek is contracted to 5 chains in width, by the near approach of the high grounds, at which point it is contemplated to raise an embankment and dam 12 feet in height above the mill pond. Cady's dam overflows about 12 acres, which will be increased by adding to the height of the dam to 120 acres, affording a spacious reservoir at comparatively small expense. Immediately above is the site for upper Oil creek reservoir: this artificial pond will cover an area of 260 acres, the principal part of which is a swamp of little value. The plan contemplates a dam and embankment 12 feet high and 25 chains in length, with the requisite gates and fixtures for drawing water and passing surplus.

Baldwin's saw-mill near the head of the lower reservoir will be destroyed, for which allowance must be made, and also for damages that will occur to Cady's mills at the lower dam. The drainage of 9,817 acres will descend into these reservoirs, and (as will be seen in the subjoined statement showing the capacity and cost of the artificial reservoirs,) is equal to 256,577,112 cubic feet.

Reservoir.	Am't of cubic feet contained in reservoir after deducting 8 per cent.	Cubic feet per minute to discharge the reservoir in 140 days.	Cost.
Ischua cr'k,	86,543,432	492.20	\$6,767.65
Lower Oil,	57,708,298	284.20	9,215.00
Upper "	125,034,624	620.20	9,080.00

Total, . . . . . 1,396.60 \$25,062.65  
Area of drainage in acres of  
Ischua creek reservoir, . . . . . 41,660  
That of Upper creek " . . . . . 9,817

It appears, then, that from the above sources, we may have a surplus over and above the quantity required of 136 cubic feet per minute, which is more than sufficient to make up any deficiency that may arise from the location of the ponds or reservoirs on the streams proposed for feeders.

The Ischua creek valley, on account of the extent of drainage, its peculiar formation, and the impervious character of the soil, is extremely well adapted to the multiplication of reservoirs. I would therefore remark, that in case any contingency should render it necessary to resort to other sources than those specified as adequate to the supply wanted, additional reservoirs may be constructed immediately above the one in contemplation at Farewell's mill-pond.

The natural flow of water from Lime, Beaver, Mud, and Fish lakes, as before stated, is 814.44 cubic feet per minute. Their capacity will be increased by raising

dams and embankments 667.70 cubic feet per minute for 140 days, (in the dry season,) equal in all to 1,482.14 cubic feet in a minute. Three artificial reservoirs, each of the same capacity of the one in contemplation at Farewell's pond, would afford 1,476.60 cubic feet per minute, and should the commissioners think it best to resort to this plan instead of using the waters of the lakes, such reservoirs can be constructed above the one proposed on Ischua creek, at an expense not very much exceeding the estimated cost of bringing the same amount of water from the lakes above mentioned.

For estimates in detail of all the reservoirs and feeders connected with the summit level, see statement 1.

From the point where the Genesee river is received into the canal to Mount Morris, is a distance of 37 miles and 35 chains. Caneadea and West Koy creeks are also taken in by means of dams and short feeders, the creeks being previously crossed by the canal in aqueducts.

Coff creek, yielding 174 cubic feet per minute, could be introduced if absolutely necessary; but as the supply of water will be abundant, I have not thought it proper to incur the expense that would be necessary for that object. The whole amount of water obtained from these several sources is 9,123 cubic feet per minute. Locks of larger lift occur from the above point to Rochester than on that portion of the route supplied from the summit, and will consequently require a proportional increase of lockage water; to provide for this, and for combinations at Round Flat and Mount Morris, I have allowed 1,147½ cubic feet per minute. The quantity required as far as Mount Morris, will be 4,891½ cubic feet per minute, leaving an amount of water over and above the demand, of 4,231½ cubic feet per minute.

Although the quantity of water necessarily wasted is very great, where so many locks occur together, as in the vicinity of Mount Morris, yet it cannot be questioned that so large a surplus as that above mentioned will be fully adequate to the supply of any contingencies arising from that cause.

Some damage will be sustained by the saw-mills upon the Caneadea and West Koy creeks in consequence of the water being taken from them in the dry season, and its passage through the race being partially obstructed at all times. No injury will be sustained by the mills at Mixville, situated at the West Koy Falls, the water being taken in below them and not setting back far enough to flood their wheels. At the point where the Genesee river is taken in, I propose to construct a guard-lock, for the purpose of receiving the lumber, produce, &c. &c., of the country around its head waters. This lock will be about two miles north of the village of Buttstown, where are several saw-mills and a sash factory, and from which, as also from many other places on the river, considerable quantities of lumber may be expected to pass annually through the canal. No other guard-locks, except those at Mount Morris, will be necessary, unless the Genesee river should be taken in as a feeder at some other point, which the following statements of the quantity of water furnished and required on both sides of the river, between Mount Morris and Rochester, will show to be unnecessary. Upon the east side, the streams which will be received into the canal are outlets of the Conesus, Hemlock, and other lakes, mentioned in a previous part of this report, which afford, together with that al-

ready in possession, 12,434 cubic feet per minute; the distance supplied from these sources being in all a fraction less than 76 miles, showing a surplus beyond the required amount of 3,732½ cubic feet per minute.

The stream on the west side, proposed as a feeder, is Allen's creek, 12½ miles south of Rochester. The total length of canal to be supplied on this route is 74,888 miles. The quantity of water at command is 12,509 cubic feet per minute; the quantity required is 10,531, showing an excess of the amount furnished over that required, of 1,978 cubic feet per minute. Allen's creek is crossed by an aqueduct with a lock of 7 feet lift connected with it, and the water is taken from the creek upon the lower lock. Notwithstanding the precaution of bringing in the water upon a level, which is depressed as much as is consistent with the safety of the work, it will be impossible to avoid injuring the hydraulic privileges at Scottsville. The water in the proposed feeder dam will rise about 4 feet above the present level of their tail races, reducing the head and fall to 14½ feet, which will give rise to a claim for damages, if the canal should be constructed upon this side of the river. The hydraulic works consist of 2 flouring mills with 7 run of stones, 1 saw-mill, 1 turning lathe, and 1 stove-mill.

Many circumstances combine to render it advantageous to take out a feeder from the Genesee river at Mount Morris, especially if the canal should be located upon the west side; among which, the necessity of drawing the whole supply of water for the canal, below Mount Morris, through the locks in that vicinity, is not the least important. Should the route upon the east side of the river be adopted, the same difficulty in relation to supplying the lower section of the canal would exist, and though there would be no absolute necessity of taking in a feeder, yet it would place the work out of danger of any disagreeable consequences which might result from neglect in passing through the necessary supply of water.

I have mentioned in a preceding part of this report, that in case of taking in the Genesee river at Mount Morris, it will be necessary for the State to take the control of the water now used there for hydraulic purposes. Upon the east side of the river damages would ensue in taking in the outlet of the Honeyoye lake, to the mills built thereon; for on account of the great height which it is necessary to build the canal to keep out of reach of the floods, the water to supply it will seriously curtail the head and fall of these mills by being dammed up against the wheels.\*

In the foregoing observations nothing has been said, nor have any calculations been made, upon the supply of water which will be furnished from the Canaseraga creek by means of the Dansville side cut. Upon this head I deem it sufficient to remark, that the 15 miles from Dansville to Mount Morris will require 2,057 cubic feet per minute, to supply which, the Canaseraga furnishes, below the confluence of mill creek, 2,458 cubic feet, leaving a surplus of 401 cubic feet per minute. The estimates for the necessary structures to supply the canal with water, are estimated on the summit, with the exception of those to be found in the sections upon which they

RECAPITULATION.

Add for contingencies and superintendence, 10 per cent., . . .	180,325 99
Total, . . .	\$1,982,485 92

Second Statement.

Aggregate cost from Olean to Mount Morris, including feeders and reservoirs, . . .	\$1,257,048 01
Mount Morris to Rochester, via west side of river, . . .	305,087 85
Dansville side cut, . . .	156,604 25
	\$1,718,740 11
Add for contingencies, &c. 10 per cent., . . .	171,874 01
Total with hammered stone locks, . . .	\$1,890,614 12

Third Statement.

Should composite locks be substituted in all cases except where combinations occur, deduct \$150 per foot lift on the amount of lockage, (704½ ft.) plus 10 per cent., . . .	116,242 00
Total with part composite locks, . . .	\$1,774,372 12

[For the Statement relative to the "Routes of Communication to the Ohio Valley," proposed and in use, from the Atlantic Cities, see No. 12 of the Railroad Journal, where it was erroneously stated as being extracted from Mr. Johnson's Report, instead of Mr. Mills'.]

From the best information I could obtain on the subject, boats of light burthen can ascend and descend the Allegheny river for about three months in the year; and from calculations made whilst at Olean, predicated upon statements made by respectable gentlemen entitled to credit, and well acquainted with the matter, property may be transported down the river to Pittsburgh for 25 cents per 100 lbs., and up to Olean \$1.20 per 100 lbs. The average time which would probably be required to make a trip from Olean to New-York, would be about 9½ days, and to return, about 10 days.

I am informed that when the Ohio river is in navigable order, the price of descending freight from Pittsburgh to Portsmouth, which, a late consequence of the opening of the trade, instead of passing the Ohio and Erie canal to New-York, passes to and from Philadelphia by means of the Pennsylvania canal road. Light goods can then be transported for 69 cents less.

can exist of the superior advantages of this route for goods going west, so long as the City of New-York is preferred by those making purchases for the western market.

To exhibit the opinion entertained of this improvement by persons interested in other avenues to the Ohio river, I subjoin an extract from the Appendix to report No. 414, of Congressional Documents, collected by the Hon. Chas. Fenton Mercer, M. C.:

"The excess in length of the present northern (Erie canal,) over the proposed southern (Chesapeake and Ohio,) route from New-York to Pittsburgh, cannot be reduced to less than 175 miles; a distance which exceeds any possible reduction of the former that can be hereafter effected, by connecting the Genesee and Alleghany rivers, a work in itself of great public utility, since it would not only cut off more than 100 miles of the distance between New-York and the head of the Ohio river, by the northern route, but save two transshipments, and the hazard of the lake navigation, as well in peace as in war; and so far greatly contribute to the value of the Erie canal, in a national as well as local view."

To be continued.]

**Saratoga and Washington Railroad.**—A charter for this Railroad, extending from Saratoga Springs to Whitehall, was procured at the last session of the Legislature, with a capital stock of six hundred thousand dollars. The books of subscription were opened in this city a few days since for the stock of this road, and the whole amount of the capital was promptly subscribed. We are informed that it is the intention of the Company to commence the construction of the road without delay. When this contemplated railroad shall be completed, it will form—in connection with the steamboat lines on the St. Lawrence river and Lake Champlain, and with the railroad now nearly finished between St. Johns and Laprarie—an uninterrupted communication by steam between New-York and this city and the great commercial emporiums of Canada, Quebec and Montreal. The advantages which this road will possess over every avenue to the South from Canada, must unquestionably secure to it almost entirely the increasing travel of the north, and must make the investment a very profitable one to the stockholders.—[Troy Whig.]

**Aurora and Buffalo Railroad.**—We learn from the Whig of yesterday, that at a meeting of the Board of Directors of this Company held on the 30th ult. Mr. William B. Gilbert, was appointed Engineer of the Road, who immediately enters upon his duties. A portion of the Road has been already located, on which operations are to commence forthwith.

The preceding paragraph is taken from the Buffalo Daily Commercial Advertiser. It indicates prosperity and enterprise amongst the inhabitants of that flourishing inland city; and it shows also the immense importance of internal improvements, to the State,—as it may, without fear of contradiction, be asserted, that, but for the construction of the Canal, there would not, in years yet to come, have been a city as Buffalo. *Daily Commercial*

the line of the canal have derived beyond our ability to estimate, works already made by the ask, are the residents giving others equal advantages receive the same every day that general

[From the forthcoming number of the Mechanics' Magazine and Register of Inventions and Improvements.]

**SURFACE OF PARABOLAS.**—This is the name for that branch of mechanical philosophy which treats of the motion of bodies projected from the surface of this earth, and influenced by the action of terrestrial gravity.

Any body projected from the mouth of a cannon must describe a conic section, having the centre of the earth in one focus, and it will describe round that focus areas proportional to the times. And it might easily be demonstrated, that if a velocity of projection were to exceed 36,700 feet in a second, the body, (if not resisted by the air,) would describe a hyperbola; if it were just 36,700, it would describe a parabola; and if less than this, it would describe an ellipsis. If projected directly upwards, in the first case, it would never return, but proceed forever, its velocity continually diminishing, but never becoming less than an assignable portion of the excess of the initial velocity above 36,700 feet in a second; in the second case, it would never return, its velocity would diminish without being extinguished; in the third case, it would proceed till its velocity was reduced to an assignable portion of the difference between 36,700 and its initial velocity, and would then return, regaining its velocity by the same degrees, and in the same places, as it lost it. These are necessary consequences of a gravitating force directed to the centre of the earth, and inversely proportional to the square of the distance. But, in the greatest projections that we are able to make, the gravitations are so nearly equal, and in directions so nearly parallel, that it would be ridiculous affectation to pay any regard to the deviations from equality and parallelism. A bullet rising a mile above the surface of the earth loses only  $\frac{1}{100}$  of its weight, and a horizontal range of four miles makes only four minutes of deviation from parallelism.

Let us therefore assume gravitation as equal and parallel. The errors arising from this assumption are quite insensible in all the uses which can be made of this theory.

The theory itself will ever be regarded with some veneration and affection by the learned. It formed the first fruits of mathematical philosophy. Galileo was the first who applied mathematical knowledge to the motions of free bodies, and this was the subject on which he exercised his fine genius.

Gravity must be considered by us as a constant or uniform accelerating or retarding force, according as it produces the descent, or retards the ascent, of a body. A constant or invariable accelerating force is one which produces a uniform acceleration; that is, which in equal times produces equal increments of velocity, and therefore produces increments of velocity proportional to the times in which they are produced. Forces are of themselves imperceptible, and are seen only in their effects, and they have no

the effect; and every thing which we can discover with regard to those measures, we must affirm with regard to the things of which we assume them as the measures. Therefore, the motion of a falling body, or of a body projected directly downwards, is uniformly accelerated, and that of a body projected directly upwards is uniformly retarded: that is, the acquired velocities are as the times in which they are acquired by falling, and the extinguished velocities are as the times in which they are extinguished.

Cor. 1. If bodies simply fall, not being projected downwards by any external force, the times of the falls are proportional to the final velocities; and the times of ascents, which terminate by the action of gravity alone, are proportional to the initial velocities.

2. The spaces described by a heavy body falling from rest, are as the squares of the acquired velocities; and the differences of these spaces are as the differences of the squares of the acquired velocities; and, on the other hand, the heights to which bodies projected upwards will rise, before their motions will be extinguished, are as the squares of the initial velocities.

3. The spaces described by falling bodies are proportional to the squares of the times from the beginning of the fall; and the spaces described by bodies projected directly upwards, are as the squares of the times of the ascents.

4. The space described by a body falling from rest is one half of the space which the body would have uniformly described in the same time with the velocity acquired by the fall; and the height to which a body will rise, in opposition to the action of gravity, is one half of the space which it would uniformly describe in the same time with the initial velocity.

In like manner the difference of the spaces which a falling or rising body describes in any equal successive parts of its fall or rise is one half of the space which it would uniformly describe in the same time with the difference of the initial and final velocities.

This proposition will be more conveniently expressed for our purpose thus:

A body moving uniformly during the time of any fall with the velocity acquired thereby will in that time describe a space double of that fall; and a body projected directly upwards will rise to a height which is one half of the space which it would, uniformly continued, describe in the time of its ascent with the initial velocity of projection.

5. It is a matter of observation and experience, that a heavy body falls rather more than sixteen feet in a second of time, and therefore acquires the velocity of thirty-two feet per second. This cannot be ascertained directly with the precision that is necessary. A second is too small a portion of time to be exactly measured without some mechanical contrivance; but it is done with the greatest accuracy by comparing the motion of a falling body with that of a pendulum.

falling through half the length of the pendulum as the circumference of a circle is to its diameter. The length of a pendulum can be ascertained with great precision, and it can be lengthened or shortened till it makes a given number of vibrations in a day.

*Airwood's machine*, which has already been described under that article, furnishes us with a very beautiful mode of illustrating the velocity which a falling body acquires in a given time. And here we may digress for an instant to point out the advantages which our modern schools of science and public lecture rooms possess over those in the "olden time." Newton is said to have had his attention directed to the subject of gravitation by the fall of an apple, and if he had desired to illustrate the subject familiarly, he must still have pursued the same course with his pupils. Instead, however, of an apple or stone descending from the roof of the lecture room, with the velocity of the wind, we now see a large brass weight, that the eye can easily follow, passing over a graduated scale, and exactly measuring the velocity it has acquired in every part of its path.

As all other forces are ascertained by the accelerations which they produce, they are conveniently measured by comparing their accelerations with the acceleration of gravity. This, therefore, has been assumed by all the later writers on mechanical philosophy, as the unit by which every other force is measured.

This has made philosophers so anxious to determine with precision the fall of heavy bodies, in order to have an exact value of the accelerating power of terrestrial gravity. Now, we must here observe, that this measure may be taken in two ways: we may take the space through which the heavy body falls in a second; or, we may take the velocity which it acquires in consequence of gravity having acted on it during a second. The last is the proper measure. The action of gravity has changed the state of the body—and this is effected by giving it a determination to motion downward; this both points out the kind and the degree or intensity of the force of gravity. The space described in a second by falling is not an invariable measure; for in the successive seconds, the body falls through 16, 48, 80, 112, &c. feet, but the changes of the body's state in each second is the same. At the beginning it had no determination to move with any appreciable velocity; at the end of the first second it had a determination by which it would have gone on for ever (had no subsequent force acted on it) at the rate of thirty-two feet per second. At the end of the second second it had a determination by which it would have moved for ever at the rate of sixty-four feet per second. At the end of the third second it had a determination by which it would have moved for ever at the rate of ninety-six feet per second, &c. &c. Thus, the difference is a determination to the rate of thirty-two feet per second. This is therefore constant, and the indication and proper mea-

be the time of  
the pen ||  
the pen ||

sure of the constant or invariable force of gravity.

It would be foreign to our present purpose to enter into any very elaborate illustration of the path of a projectile as applied to the science of gunnery, and it may be enough to furnish our readers with a familiar view of the general effects of gravitation as applied to the subject.

In the above diagram *a d b* represent the horizontal path of a ball supposed to be projected from the point *a*. Now, in this case we suppose the existence of no gravitating force; but, as there is a continual tendency in all bodies to approach towards the earth's surface, we must place the cannon at *c* if we wish the ball to arrive at *b*. This is a necessary result of the law which draws all bodies towards the earth's centre. Instead of placing the piece at the elevation shown in the diagram, the gunner elevates the point of his piece, and by giving it an ascending range ensures his object with equal certainty. Thus he would direct his piece from *a* in the direction of *c*, and although it would not take precisely the path *a c*, yet it would go for a certain distance nearly in a straight line, and then change its path till it arrived at *b*, a little beyond which it would strike the ship. The British sailors, from long experience and much practice, rather than from a high degree of science, have obtained considerable precision in the range of their guns.

In the practice of cannonading it is necessary to come as near as possible to the object aimed at, as the hurry of service allows no time for geometrical methods of pointing the piece after each discharge. The gunner either points the cannon directly to the object, when within 200 or 300 yards of it, in which case he is said to shoot point blank; or, if at a greater distance, he estimates to the best of his judgment the deflection corresponding to his distance, and points the cannon accordingly. Or lastly, when the intention is not to batter, but to rake along a line occupied by the enemy, the cannon is elevated at a considerable angle, and the shot discharged with a small force, so that it drops into the enemy's post, and bounds along the line. In all these services the gunner is directed by his practice.

The principal use of the parabolic theory is to direct the bombardier in throwing shells. With these it is proposed to break down or set fire to buildings, to break through the vaulted roofs of magazines, or to intimidate and kill troops by hurting among them. These objects are always under cover of the enemy's works,

and cannot be touched by a direct shot. The bombs are therefore thrown upwards, so as to pass over the defences and produce their effect.

These shells are frequently many hundred pounds in weight. The mortars from which they are discharged must, therefore, be very strong, that they may resist the explosion of gunpowder which is necessary for throwing such a mass of matter to a distance. Very little change can be made in their elevation, and therefore their ranges are regulated by the velocities given to the shell. These again are produced by the quantities of powder in the charge; and experience (confirming the best theoretical opinions that we can form of the subject) has taught us that the ranges are nearly proportional to the quantities of powder employed, only not increasing quite so fast. This method is much easier than by differences of elevation; for we can select the elevation which gives the greatest range on the given plane, and then we are certain that we are employing the smallest quantity of powder with which the service can be performed: and we have another advantage, that the deviations which unavoidable causes produce in the real directions of the bomb will then produce the smallest possible deviation from the intended range.

The only other circumstance in which we are interested is the time of the flight. A knowledge of this is necessary for the bombardier, that he may cut the fuses of his shells to such length as that they may burst at the very instant of their hitting the mark.

In making experimental observations on the path of a projectile, a jet of water or mercury gives us the finest example, because we have been prohibited to view the descent of the water even in these cases, as it can be observed on a horizontal surface fully traced and held close by the distance between the curve and the distance between it and the spout, and that the descending branch of the curve takes a more perpendicular direction than the ascending branch. And this difference is more remarkable as the jet is made with greater velocity, and reaches to a greater distance. This is evidently produced by the resistance of the air, which diminishes the velocity, without affecting the gravity of the projectile. It is still more sensible in the motion of bombs. These can be traced through the air by the light of their fuses; and we see that their highest point is always much nearer to the mark than to the mortar on a horizontal plane.

The greatest horizontal range on this plane should be when the elevation is 45 degrees. It is always found to be much lower.

The ranges on this plane should be as the sines of twice the elevation. A ball discharged at the elevation of  $19^{\circ}5'$ ,

ranged 448 yards; at the elevation of  $9^{\circ}45'$ , 330 yards. It should have ranged by theory 241 yards.

The range at an elevation of  $45^{\circ}$  should be twice the impetus. And it has been found by experiment that a musket ball, discharged with the usual allotment of powder, has the velocity of 1700 feet in a second. This requires a fall of 45,156 feet, and the range should be 90,312, or  $17\frac{1}{2}$  miles; whereas it does not much exceed half a mile. A twenty-four pound ball, discharged with sixteen pounds of powder, should range about 16 miles; whereas it is generally short of three miles. As the motion of projectiles is performed in the atmosphere, it follows that the air is displaced or put in motion. Whatever motion it acquires must be taken from the bullet. The motion communicated to the air must be in the proportion of the quantity of air put in motion, and of the velocity communicated to it. If, therefore, the displaced air be always similarly displaced, whatever be the velocity of the bullet, the motion communicated to it, and lost by the bullet, must be proportional to the square of the velocity of the bullet and to the density of the air jointly. Therefore, the diminution of its motion must be greater when the motion itself is greater, and in the very great velocity of shot and shells it must be prodigious. It appears from repeated experiments, that a globe of four inches and a half in diameter, moving with the velocity of twenty-five feet in a second, sustained a resistance of 315 grains, nearly three-quarters of an ounce. Suppose this ball to move 800 feet in a second, that is, thirty-two times faster, its resistance would be  $32 \times 32$  times three-quarters of an ounce, or 768 oz., or 48 lbs. This is four times the weight of a ball of cast iron of this diameter; and if the initial velocity had been 1600 feet per second, the resistance would have been at least sixteen times the weight of the ball. It is indeed much greater than this.

This resistance, operating constantly and uniformly on the ball, must take away four times as much from its velocity as its gravity would do in the same time. We know that in one second gravity would reduce the velocity 800 to 768, if the ball were projected straight upwards. This resistance of the air would therefore reduce it in one second to 672, if it operated uniformly; but as the velocity diminishes continually by the resistance, and the resistance diminishes along with the velocity, the real diminution will be somewhat less than 128 feet. We shall, however, see afterwards, that in one second its velocity will be reduced from 800 to 687. From this simple instance, we see that the resistance of the air must occasion great deviation from parabolic motion. In order to judge accurately of its effect, we must consider it as a retarding force, in the same way as we consider gravity.

If we consider this resistance as a retarding force, we can compare it with any other such force by means of the retardation which it produces in similar

circumstances. We may compare it with gravity by comparing the diminution of velocity which its uniform action produces in a given time with the diminution produced in the same time by gravity. But we have no opportunity of doing this directly; for when the resistance of the air diminishes the velocity of a body, it diminishes it gradually, which occasions a gradual diminution of its own intensity. This is not the case with gravity, which has the same action on a body in motion or at rest, so that we cannot observe the uniform action of the air's resistance as a retarding force. We must therefore substitute some other way of making the comparison. We can state them both as dead pressures. A ball may be fitted to the rod of a spring steelyard, and exposed to the impulse of the wind. This will compress the steelyard to the mark 3, for instance. Perhaps the weight of the ball will compress it to the mark 6. We know that half this weight would compress it to 3. We account this equal to the pressure of the air, because they balance the same elasticity of the spring. And in this way we can estimate the resistance by weights whose pressures are equal to its pressure, and we can thus compare it with other resistances, weights, or any other pressures. In fact, we are measuring them all by the elasticity of the spring. This elasticity in its different positions is supposed to have the proportions of the weights which keep it in these positions. Thus we reason from the nature of gravity, no longer considered as a dead pressure, but as a retarding force; and we apply our conclusions to resistances which exhibit the same pressures, but which we cannot make to act uniformly.

The most elaborate mathematical calculations lead us to the following important results.

1. Balls of equal density, projected with the same elevation, and with velocities which are as the square roots of their diameters, will describe similar curves. This is evident, because in this case the resistance will be in the ratio of their quantities of motion. Therefore, all the homologous lines of the motion will be in the proportion of the diameters.

2. If the initial velocities of balls projected with the same elevation are in the inverse sub-duplicate ratio of the whole resistances, the ranges, and all the homologous lines of their track, will be inversely as those resistances.

These theorems are of considerable use, for by means of a proper series of experiments on one ball projected with different elevations and velocities, tables may be constructed which will ascertain the motion of an infinity of others.

We shall conclude this article by giving two or three tables, computed from the principles established above, and which serve to bring into one point of view the principal circumstances of the motion in a resisting medium. In a series of experiments made at Woolwich, which were continued for several days, not only do the experiments of one day

differ among themselves, but the mean of all the experiments of one day differs from the mean of all the experiments of another no less than one fourth of the whole. The experiments in which the greatest regularity may be expected, are those made with great elevations. When the elevation is small, the range is more affected by a change of velocity, and still more by any deviation from the supposed or intended direction of the shot.

2	92	420
4	121	428
9	159	456
18	200	470
32	272	479

The first table shows the distance in yards to which a ball projected with the velocity of 1600 will go, while its velocity is reduced one tenth, and the distance at which it drops sixteen feet from the line of its direction. This table is calculated by the resistance observed in Mr. Robins' experiments. The first column is the weight of the ball in pounds. The second column remains the same whatever be the initial velocity, but the third column depends on the velocity. It is here given for the velocity which is very usual in military service, and its use is to assist us in directing the gun to the mark. If the mark at which a ball of twenty-four pounds is directed is 474 yards distant, the axis of the piece must be pointed sixteen feet higher than the mark. These deflections from the line of direction are nearly as the squares of the distances.

2800		5293	2762	5430
3000		5455	2862	5596
3200				5732

The next table contains the ranges in yards of a twenty-four pound shot, projected at an elevation of 45°, with the different velocities in feet per second expressed in the first column. The second column contains the distances to which the ball would go in vacuo in a horizontal plane; and the third contains the distances to which it will go through the air. The fourth column is added to show the height at which it rises in the air; and the fifth shows the ranges corrected for the diminution of the air's density as the bullet ascends, and may therefore be called the *corrected range*.—[Partington.]

[From the London Mechanics' Magazine.]

**LIVERPOOL AND MANCHESTER RAILWAY.**—We have great pleasure in laying before our readers a complete copy of the Report made by the Directors of this Railway to their constituents at their last half-yearly meeting (the sixth), on the 22d of January last, when, as stated in our last, a dividend of £4 10s. per share (for the half year) was declared. It furnishes another most complete answer to the calumnies of Mr. Cort and his patrons; showing that, after paying all expenses ("interest" on loans included) during the past half-year, there remained a nett balance of profit of £40,346 6s. 7d. The Directors, it will be observed, have resolved to discontinue the practice which they have hitherto followed, "of publishing minute particulars of the traffic, with detailed subdivisions and classifications of the disbursements." The practice was a good one, and we are sorry that it has been departed from. The hit at the "Navigation Companies," for not furnishing "their quota to the general stock" of statistical information on the subject of inland transports, is very fair; but the more these bodies are to blame in this respect, the more it would have been to the honor of the Liverpool and Manchester Railway Directors to persevere in the patriotic and enlightened course they at first adopted, of laying the fullest possible information on every branch of their proceedings before the public.—[Ed. L. M. M.]

#### Liverpool and Manchester Railway—Sixth Half-Yearly Meeting.

##### REPORT.

Liverpool, January 21, 1835.

The Directors are happy to inform the Proprietors that the business of the Company in the last half-year appears to have been gradually on the increase compared with that of the corresponding six months in former years. The following is a statement of the receipts in the different departments, and of the disbursements, exhibited under the usual heads for the same period:—

##### HALF YEAR ENDING 31ST DECEMBER, 1834.

##### Receipts.

Coaching Department, . . . . .	£60,892 7 4
Merchandise do. . . . .	41,197 18 6
Coal do. . . . .	3,406 16 4
	£104,899 2 2

##### Expenses.

Bad Debt Account, . . . . .	£292 2 6
Coach Disbursement Account, viz.: guards and porters' wages, £1,205 3s. 3d.; parcel carts, horse-keep and drivers' wages, £365 10s. 2d.; materials for repairing, £1,131 16s. 11d.; men's wages repairing, £1,505 7s. 5d.; gas, oil, tallow, cordage, &c., £155 11s. 3d.; duty on passengers, £3,284 12s.; stationery and petty expenses, £308 19s. 1d.; taxes, insurance, &c., on offices and stations, £171 16s. 1d., . . . . .	8,128 16 2
Carrying Disbursement Account, viz.: agents' and clerks' salaries, 1,804l. 12s. 9d.; porters' and brakesmen's wages, 5,023l. 14s. 8d.; gas, oil, tallow, cordage, &c., 208l. 3s. 5d.; repairs to jiggers, trucks, stations, &c., 581l. 4s. 9d.; stationery and petty expenses, £487 15s. 9d.; taxes, insurance, &c., on offices and stations, 451l. 8s. 8d., . . . . .	8,562 0 0
Coal Disbursement Account, . . . . .	220 1 8
Cartage (Liverpool) do. . . . .	59 16 8
Do. (Manchester) do. . . . .	3,247 2 3
Charge for Direction do. . . . .	301 7 0
Compensation (Coaching) do. . . . .	43 1 11
Compensation (Carrying) do. . . . .	222 19 8
Coach-office Establishment do., viz.: agents' and clerks' salaries, 601l. 15s.; rent and taxes, 74l. 10s., . . . . .	676 5 0
Engineering Department Account, . . . . .	352 10 0
Interest do. . . . .	6,725 14 5
Locomotive Power do., viz.: . . . . .	

coke and carting, 3,654l. 7s. 5d.; wages to coke fillers and watering engines, 349l. 15s. 10d.; gas, oil, tallow, hemp, &c., 932l. 8s. 10d.; copper, brass, iron, timber, &c., for repairs, 3,995l. 19s. 9d.; men's wages repairing, 4,892l. 3s. 2d.; enginemen and firemen's wages, 815l. 12s. 7d.; out-door repairs to engines, 1,290l. 3s. 1d.; three new engines, 2,890l. 13s.; new boiler and shed at water station, 233l. 8s. 11d.	18,364	12	7
Law Disbursement Account, . . . . .	100	0	0
Maintenance of Way do, viz.: wages and small materials, 4,163l. 0s. 10d.; stone blocks, sleepers, &c., 1,082l. 10s. 4d.; new rails, chairs, points, crossings, &c., 2,500l. 11s. 3d.; ballast and leveling, 217l. 6s. 5d.	7,963	8	10
Office Establishment Account, viz.: salaries, 767l.; rent and taxes, 70l. 10s.; stationery, &c., 49l. 11s. 1d.	887	1	1
Police Account, . . . . .	1,033	4	4
Petty Disbursement Account, . . . . .	40	0	0
Rent do, . . . . .	233	15	0
Repairs to Walls and Fences do, . . . . .	712	9	9
Stationary Engine Disbursement Account, viz.: coal, 303l. 16s. 3d.; engineman and firemen's wages, 102l. 6s.; materials and repairing, 63l. 9s. 9d.; gas, oil, tallow, &c., 53l. 15s. 5d.; deepening engine wells, 44l. 2s. 6d.	567	9	11
Tunnel Disbursement Account, viz.: brakemen's wages, 226l. 3s.; gas and repairs, 91l. 19s. 8d.; new sheaves, oil, cordage, &c., 90l. 14s. 4d.	408	17	0
Tax and Rate Account, . . . . .	2,729	17	6
Wagon Disbursement do, smiths' and joiners' wages, 1,307l. 11s. 10d.; steel, iron, timber, &c., 1,322l. 10s. 10d.; cordage, grease, paint, oil, &c., 149l. 19s. 8d.	2,680	2	4
	64,552	15	7
Nett profit for six months, . . . . .	40,346	6	7

Statement of Receipts and Expenditure on Capital Account, from the commencement of the undertaking to 31st December, 1834.

TREASURER, Dr.	£	s.	d.
To amount of Joint Capital in Shares and Loans, . . . . .	1,151,185	0	0
Ditto of Dividends not paid, . . . . .	1,426	17	5
Ditto of Reserved Fund and Interest, . . . . .	3,930	13	6
Surplus in hand after payment of the 5th Dividend in August, 1834, . . . . .	164	11	0
Nett Profits of the Concern for the half year ending 31st December, 1834, . . . . .	40,346	6	7
	£1,197,053	8	6

TREASURER, Cr.	£	s.	d.
By amount of Expenditure on the Construction of the Way and the Works, including the Tunnel Excavations, &c., now in progress, . . . . .	1,156,563	18	3
Ditto in the hands of Moss & Co., Bankers, . . . . .	23,790	14	6
Ditto in the hands of the Treasurer, . . . . .	117	4	8
Ditto Arrears of Calls, . . . . .	18	8	6
Ditto Balance of Book Debts due to the Company, . . . . .	16,563	2	7
	£1,197,053	8	6

On the subject of the accustomed half-yearly reports, the Directors beg leave to recommend to the proprietors a departure from the plan hitherto pursued, of publishing minute particulars of the traffic, with detailed subdivisions and classifications of the disbursements; and in doing so, they will state briefly some of the reasons which have led them to this recommendation.

The Liverpool and Manchester Railway being the first great undertaking of the kind, the Directors, on the opening of the line, were aware that according to the measure of its success would be the probability of similar enterprises, founded on this first experiment; every step, therefore, in their proceedings, whether with reference to extent of traffic, mechanical improvements, or financial results, was interesting, as

well to the public as to the proprietors; and under that conviction the Directors published, half yearly, those minute details of the concern, which have found their way into every portion of the globe. It was obvious, also, that had their example in this respect been followed by the conductors of the great Water Conveyances, so far at least as regards the extent and gradual increase of their aggregate traffic, whether comprising raw materials, moving from the seaport into the interior, or manufactured commodities brought from the country to the port for shipment, valuable statistical information might have been obtained.

During four years the Directors have pursued the plan of unreserved publicity; their difficulties and their mistakes; but notwithstanding these—their success in the great features of their undertaking, have been made familiar to the public. The subject is now understood in all its parts, and so well satisfied are the public and the legislature with the general result, that the construction of railways in great lines from north to south of the kingdom, has become a distinguishing mark of the present age. The object of publicity has thus been gained. It has been determined by the country and the government that railways shall proceed; and the extent to which they will hereafter be carried will depend on the success, not of the Liverpool and Manchester line, but of those great works which are now in progress. The Directors are of opinion, therefore, that the time has come when they may fairly be allowed to consult the interest and convenience of the Railway Company, regarded as a great mercantile concern, whose proceedings may henceforward be considered as matters of business, in which the proprietors alone are concerned. It is obvious that no statistical information can be expected from the publication of their accounts, as none of the Navigation Companies, the great rivals and competitors of the Railway, will furnish their quota to the general stock. Such existing railways also as have up to the present period been completed, have forborne to furnish any detailed statements of account; and the Directors are not aware that the conductors of the great north and south lines, now in course of execution, intend to deviate from the general rule; neither, perhaps, should it be considered matter of surprise, that the managers of other concerns, regarding the conduct of their several undertakings, exclusively in the way of business, and with a view to the commercial interests of their respective proprietors, should decline exposing gratuitously the extent and character of their operations, and the exact increase or decrease of their traffic, with its corresponding profit or loss, to the examination of rival or opposing establishments.

On the subject of locomotive power, the Directors have again to observe, that they consider the travelling engines to be in a state of gradual but marked improvement. The superintending mechanics of the Company, by lengthened experience, unremitting attention, and constant examination of the working of the various engines, have endeavored to add some improvement to each machine as it has passed successively through their hands. And the Directors feel no hesitation in stating, that the trips of the locomotive engines, for the last six months, have been performed with a speed and regularity superior to what has been accomplished in any former period. The disbursements in this department for the last six months are heavy, but they include

the cost of three new and powerful engines, and the entire re-construction with new materials of a fourth, with the exception only of the cylindrical boiler. Whilst alterations were continually making, and improvements suggested, the Directors were unwilling to have on hand a large stock of imperfect machines: they are now of opinion, however, and they have begun to act on that opinion, that with their present experience it will be advantageous to increase their supply of locomotive engines, and so provide for all needful repairs being effected with less of night work; and with that completeness which is impossible when engines are, of necessity, hurried out of the repairing shops, in order that the ordinary traffic of the line may not be stopped. Engineers and scientific men from different parts of the world are not unfrequent visitors at the Company's workshops, which are at all times accessible for the benefit of the public—whether for the purpose of scientific research, or of practical information.

The excavation of the new tunnel from Wavertree-lane to Lime-street is opened throughout its whole length, and will soon be ready for laying down the blocks and rails.

The Directors, in former reports, have alluded to the course which they had considered it expedient to adopt of substituting heavier and stronger rails in place of those which from time to time had been bent or broken, owing to the service to which they were subjected, from the speed and weight of the engines, being far more severe than was originally contemplated. From experience of the decided superiority of those parts of the way which have already been laid with the stronger rails, the Directors feel the propriety of proceeding to relay with heavier and stronger rails such portions of the line as have from time to time to be taken up for the purpose of substituting stone blocks for the original wooden sleepers; and they doubt not, in so doing, they shall obtain the concurrence of the proprietors.

By the foregoing statement of accounts it appears that there is a nett disposable profit for the half-year of . . . . . 40,346l. 6s. 7d. Which added to the surplus from the last half-year . . . . . 164l. 11s. 0d.

Amounts to . . . . . 40,510l. 17s. 7d. Out of this sum the Directors recommend that a dividend be now made to the proprietors of £4 10s. per £100 share, amounting to £35,850. That £3,000 be appropriated to the relaying of the way with stronger rails; and that the remaining sum of £1,651 17s. 7d. be carried as a general balance to the next half-year's account.

CHARLES LAWRENCE, Chairman.

Steamboat Navigation on Lake Ontario.—The Steamboat Oswego commenced the season of Steamboat navigation on the morning of the 5th. She left our harbor in beautiful style bound for the Genesee river, Toronto, (U. C.) and Niagara. She has taken the lead upon the lake and gives strong proof of her ability to maintain it. The firmness, nautical skill and experience of her commander, Capt. Homans, entitle him to claim from the public the highest degree of confidence. [Oswego Palladium.]

The books of the Sea Insurance Company are to be opened to-morrow, and the two succeeding days at the Union Bank. We understand their charter, in addition to Marine Insurance, gives extensive privilege for insurance on our inland navigation and transportation routes, which has been much needed, and offers very favorable prospects for investment. M.

## NEW-YORK AMERICAN.

APRIL 11—17, 1833.

## LITERARY NOTICES.

**THE CRAYON MISCELLANY—A TOUR ON THE PRARIES.** BY THE AUTHOR OF THE SKETCH BOOK, 1 VOL. : Philadelphia, CAREY, LEA & BLANCHARD. We have perused this eagerly anticipated volume with unalloyed delight. We received it only last evening and sat down at first merely to take a taste of it; to turn over a few pages and see how the author had treated his object, and then to reserve the book for quiet and leisurely enjoyment afterward. In this mood we re-read the introduction, (which has already found its way into the papers, and which is decidedly among the most felicitous pieces of Mr. Irving's writings, exquisite in style, and noble in sentiment) we next looked a little further in advance, in order to discover the immediate scenes, the author had before him—and then learning the precise quarter in which he was bound, we could not lay down the book without ascertaining who were to be his companions. We made the acquaintance of each almost before we were aware of it and became interested in the part which each was to take in the wild expedition before him.—We were anxious to see them all well mounted and fairly started on their journey.—We could not help following them to their general rendezvous. They crossed the border—and still we lingered near to witness their first interview with the rangers. They began their march.—The bugle rang out on the soft air of a still Indian summer morning.—The mounted riflemen filed off slowly beneath the boughs of the rich autumnal forest.—The hunters and trappers spurred more eagerly along the flanks, and shot off in the adjacent prairies. We watched the gleam of their rifles as their forms were gradually lessened and lost over the rolling plain, and the shouts of *Tunish* echoed back by his half-breed compeers as the last pack horse disappeared in a ravine, came distinctly upon our ears. We looked around over the grassy domain, diversified with its scattered groves and forests and glassy pools, reflecting their painted foliage: we moved a little to catch an other glance of the last straggler that remained to give life to the landscape, and before he had joined the column, we found ourselves galloping by his side, and in full career over the Grand Prairie. Nor could we then tear ourselves from the party until their wayworn and jaded horses, after many a buffalo hunt and wild foray were stabled once more at Cantonment Gibson, and their riders had dispersed to their distant homes. In a word we never laid down the book until we had read it completely through. He who feels the slightest interest in the kind of life here described, will find no where so captivating, and yet thoroughly faithful a picture of its realities as is presented in Mr. Irving's work. He who has once tasted it, will burn at every page to be once more upon the prairies. There is no story in the book—no single tissue of strange adventure—no train of declamatory common places and theatrical sentiment. It is simply a picture of life—a picture drawn with the most easy and unaffected hand—but laid in colors, rich, warm and enduring—for the style of the writer like the Claude-like atmosphere of our Indian summer, embalms every object in mellow yet glorious repose.

[A number of beautiful passages meant to accompany this notice, shall appear hereafter.]

## ADVICE TO A BROTHER:

**MISSIONARY REMAINS.** New York: Taylor & Gould, Brick Church Chapel.—These two works of religious instruction, are very handsomely printed 18mos. The first is written by a Missionary, and the second, which commemorates the lives of those of his departed brethren, is a brief, but not inelegant eulogy, by the Rev. Dr. Spring.

**THE BOOK OF SCIENCE, Part I—Mechanics.** Philadelphia: Cary, Lea & Blanchard.—This little work is a familiar introduction to the principles

of natural philosophy, adapted to the comprehension of young people; and as an elementary treatise, we should think it would prove valuable. It appears to be prepared with care and simplicity, and it is well illustrated with all the necessary diagrams and figures.

**VALEMIUS, A ROMAN STORY, 2 vols.** Harper's.—We are happy to meet with a republication of this excellent work of Lockhart. The time which has elapsed since its first appearance, has confirmed the favor of its reception, and established Valemius as one of the standard novels of the day. The beauty of the style, the interest of the story, and the affecting scenes it describes, during the early struggles of Christianity, under the Roman emperors, recommend this work to every reader of taste and feeling.

**ELEMENTS OF ALGEBRA—TRANSLATED FROM THE FRENCH OF M. BOURDON. REVISED AND ADAPTED TO THE COURSES OF MATHEMATICAL INSTRUCTION IN THE UNITED STATES; BY CHARLES DAVIES, PROFESSOR OF MATHEMATICS IN THE MILITARY ACADEMY. WILEY & LONG; NEW YORK.**—This work has been already mentioned in these columns; but as it is likely to exert considerable influence upon the progress of mathematical science in this country, it deserves something more than a passing notice.

In the mathematical and physical sciences, France has for a long time held undisputed pre-eminence, and is at this moment enjoying in every department of life, the fruits which have rewarded the labors of her men of genius. Laying aside the unwieldy weapons and cumbersome armor of the ancient methods, she has substituted for them the more refined, the less pompous and intimidating to vulgar eyes, but the infinitely more efficient system of the modern analysis.—Whilst this has been perfecting itself, and producing the most brilliant and stupendous effects in France, England has been content to plod on in the good old way, and not until quite recently has her pride allowed her to acknowledge the superiority, and to follow in the steps of her rival. To say however, that France has done every thing for the mathematics and England nothing, would be absurd. The latter pursuing a different path, has also, gathered choice fruits though of a different kind. The great distinction between the two nations, where they have occupied common ground, is, that the one has been too exclusively theoretical, the other too purely practical. The advice of Laplace—"Give the preference, in teaching to general methods, endeavor to present them in the most simple manner and you will see at the same time, that they are almost always most easy." (Journal des Sciences de l'Ecole Normale,) expresses the method which the French mathematical writers have adopted. In observing this however, they have too much neglected illustrative examples, by which the student might acquire practical skill in the application of theory. The English writers on the other hand, abundantly exhibit the *modus operandi*, but omit the demonstration of the principles upon which it depends; whereby one of the chief benefits of mathematical study, namely, the exercise of the reasoning faculties, is lost.

The above remarks if just, show the importance of that feature in the plan of the work which has called forth this article mentioned in the following paragraph of its preface. "It has been the intention to unite in this work, the scientific discussions of the French, with the practical methods of the English school; that theory and practice, science and art may mutually aid and illustrate each other."

The Algebra of La Croix, a treatise of the highest merit, was the one formerly most used in France. It was translated into English, some years since by Professor Farrar of Harvard College, and has had an extensive circulation in this country.

Bourdon's Algebra, soon after its publication,

was adopted by the University of Paris, and has superseded that of La Croix, at most of the Mathematical schools in the kingdom. Its excellence lies, not alone in the matter which it contains, but also in the admirable order, and clearness, with which it is presented. It was translated in part by Professor De Morgan, of the London University, and is in use at the University of Cambridge. A translation was made by Lieut. Ross of the Military Academy, West Point for the use of the Cadets, in the year 1831. In the hands of the present Editor, it has undergone great alterations. An occasional diffuseness rendering it tedious and obscure has been corrected, a few demonstrations have been replaced by better ones, and some unimportant matter has been omitted, and other more valuable, including a great variety of examples, judiciously selected, from the best English practical works, has been introduced. Even the arrangement of the matter upon each page, indicates the hand of one who has observed the importance of not neglecting the most trifling helps which can facilitate the progress of the student.

The work is in all respects, what might be expected from the distinguished gentleman, who has been for many years at the head of the department to which it belongs, in the best Mathematical School in the country.

**FIRST LESSONS IN POLITICAL ECONOMY, by Jas. McVickar, D. D., Professor of Political Economy, Columbia College, New York.** Boston: Hilliard, Gray & Co.—We cannot better promote the dissemination of this excellent little elementary work, than by giving Professor McVickar's views of his subject, as laid down in his preface. His name alone is a sufficient guarantee how these views will be carried out:

The first principles of Political Economy are truths which a child may understand, and which children should therefore be taught. In the last century they were among the speculations of the learned; they have now become the heritage of the nursery; and the only difficulty in teaching them in after life arises from a suspicion excited by their very simplicity. They are so obvious, that men are apt to think, if true, they would not have them, for the first time to learn them. That this stumbling block may be removed from the path of the next generation, we must now incorporate these truths into the studies of children, in order that they may become, as it were, "part and parcel of their minds." From such a course, we have reason to believe, would flow many and great advantages. Men in high and responsible stations would then no longer be found engaged in learning principles when they should be occupied in applying them, nor in discussing theories when they should be directing practice; for certainly to see statesmen, as we now do, disputing about the laws of currency when called upon to regulate it, is an absurdity as great as to see engineers upon the field of battle commencing their dispute as to the principles of the law of projectiles. In either case it is a discussion foreign to their business, and originating in a culpable ignorance of what they should before have learned. To question the principles of science is always the part of ignorance. The true difficulty in Political Economy, and it no doubt is a great one, lies in the modification which peculiar circumstances produce upon the results of general laws. This is the true field of practical inquiry—not principles—they are fixed and uniform. In economical as in all other sciences, theories have power to mislead only so long as the principles of science continued unsettled. So soon as men cease to dispute about the ground upon which they set out, then, and not before, do they take up questions in the plain light of fact and experience.

With a view to do his share toward forwarding this good work, which, as academic teacher of the science, he feels himself by duty called upon to do, the Author proposes to prepare a series of text books on these subjects, in a manner suited to the varied ages and capacity of those for whose instruction they are intended, being

1. First Lessons in Political Economy, for primary and common schools.

2. Outlines of Political Economy, for higher schools and academies.

3. Lectures on Political Economy, for the use of elder students in colleges.

Such a scheme as this, though it had been long before his mind, and materials for it partly prepared, might yet, he is well aware, have slumbered on much longer, had not a recent work of Whately, entitled "Easy Lessons on Money Matters," recalled to his mind, together with a conviction of the expediency of no longer delaying what is evidently in our country so greatly needed; for if universal suffrage make every man a legislator, universal education must fit him for the task. To employ his power wisely and well, he must at any rate not be ignorant in those matters in which legislation is concerned.

For Number 1. in the series, a republication of Whately was first thought of, with questions annexed; but this idea was soon abandoned, from the inapplicability of the work to the circumstances and needs of our country. The Author has therefore proceeded to give his own views, and in his own way, in reference to the wants of his fellow citizens; retaining, however, the first lesson, or that on "Money," as given by Whately, in order that an humble imitator of his method may not seem to claim a merit of originality to which he is not entitled.

#### FOREIGN INTELLIGENCE.

**LATEST FROM ENGLAND.**—By the packet ship Europe, Captain Marshall, arrived last evening, we have London papers of the 17th, and Liverpool of the 18th, inclusive. They contain little of interest except that the ministry continued, and apparently, firm in their seats. The only items of interest will be found under head of Foreign News. The Cotton market is improving.

#### SPAIN.

We have received by express Madrid papers of the 7th inst. and private letters from that capital of the 8th. The health of Martinez de la Rosa is spoken of as becoming daily more feeble, but the new Minister at War (General Valdez) was displaying the utmost energy and activity in despatching reinforcements to General Mina. The 5th Regiment of the Line had left Madrid for the north on the 7th, and on the next day was followed by the provincial regiments of Ronda and Seville. These three regiments were to be joined at Fuencarral, a village a few leagues to the north of Madrid, by the Albuera and Valencia volunteers, and with them were to be formed into a separate division, to be placed under the command of General Cordova, who was to replace General Carratala, the latter having been appointed Captain General of Murcia and Valencia. It was expected that early in the spring the numerical force under Mina would be raised to 60,000 men.

#### PORTUGAL.

The private letters from Lisbon, by the mail of yesterday morning, add little to our news from thence, but the annexed extract from one of them is interesting, as showing what an alteration for the better has been produced in that capital by the recent changes in the Government:

"LISBON, MARCH 4.—For those who saw Lisbon three months ago, and who see it at the present day, our city has completely changed its aspect.—No one is any longer insulted in the streets on account of his former political opinions. It seems as if the Pedrites had at length come to an agreement, not perhaps completely to forget the past, but to adopt the appearance of recollecting it as little as possible. Our carnival has been more brilliant than for many years before, and it was a great pleasure to see both men and women cordially meeting in the same drawing room, one half of whom had much to pardon to the other half.—Our Government has returned, without any kind of confusion, to the Constitutional line, from which it ought never to have diverged. There are no longer in the Council any but responsible Ministers. The Duke of Palmello, who was President, holding a portfolio, is now Minister of Foreign Affairs. The Prince applies himself to public affairs as much as he can and ought, and it is remarked with esteem for his character, that two of the Ministers, who both spoke and even voted

against his marriage with the Queen, not only remain in the administration, but are treated by him with as much kindness as the rest. The Prince is very active. He visits all our public establishments in turn, and examines them with care, so as to be able to assist hereafter in remedying what is defective in them. The opposition in the Chambers has certainly not renounced its principles, and ought not to do so, but relying on the Prince's declaration in his speech to the Peers, it becomes every day more calm and moderate. The Minister of the Interior is gaining popularity in his new office. A little time hence, and I trust not the slightest trace will remain of our divisions and misfortunes. The Queen and her husband are accessible to all, indulge in no luxury or ostentation, and live together in a harmony which promises both them and us many happy days."

The supplement to the Literary Advertiser for 1834 contains lists of the new books and principal engravings published in London during the past year, with their sizes and prices. The number of books is about 1,270, exclusive of new editions, pamphlets or periodicals, being upwards of 100 more than in 1833. The number of engravings is 73 (including 31 portraits, 15 of which are engraved in the line manner, 49 in mezzotint, &c.

The London Morning Chronicle, of the 9th ultimo, says—"The poets Thomas Moore, William Wordsworth, and Robert Southey, are all at present in London, and each of them preparing to publish a new work."

A recent London Gazette contains the appointment of Sir Howard Douglas (not Sir Robert Wilson) to be Lord High Commissioner of the Ionian Islands.

The new scheme of church reform in England, will fix the income of the Archbishop of Canterbury at 10,000*l.*, and that of the Archbishop of York at 8,000*l.*, while the salaries of the other bishops are to be equalized at 5,000*l.* a year. Of course these arrangements must be prospective. A plan distinguished for its ingenuity, has been submitted to the commissioners with a view of procuring the immediate abolition of pluralities. We are not at liberty to state the details. —[London Courier.]

**LONDON AND PARISIAN FASHIONS.**—*Beginning of March.*—Ball dresses are generally ornamented with bouquets of flowers, placed one side of the *jupon*, and extending from the waist to the feet. Wreaths are sometimes used instead of detached bouquets. A dress lately made by a distinguished Parisian milliner was composed of white crape, and ornamented up one side with five bouquets of flowers of different hues: one bouquet was of pink roses, another of blue hyacinths, and a third of clematis, &c. In short, a whole *parterre* seemed to have been laid under contribution for the adornment of this beautiful dress. The *coiffure* worn with it was a repetition of the trimming of the robe, and consisted of a crown formed of all the flowers introduced in the bouquets.

Another much admired ball dress was of pink gauze over a slip of pink *poult-de-soi*. Three bouquets of white flowers were placed at the height of the knee, and fastened three pink satin ribbons which ascended diagonally to the waist, and were gathered under the bow of the *ceinture* on one side. On each shoulder a bunch of white flowers, widening on the sleeves, and confining its folds. Head-dress, two white flowers on each temple, fastened into paintings of hair à la *Clotilde*. In the centre of the forehead a cameo, suspended by a fine gold chain.

Turbans of the form styled à la *Suisse* are much worn, and are extremely becoming to an oval and regular countenance. The *bandelette* which passes under the chin has a very pretty effect.

With dresses of velvet or rich silk and satin, mantillas of *dentelle de soi* are more generally adapted than those of blonde or *point d'Angleterre*.

The following dresses have been worn at some of the most fashionable parties of the season.

1. An open robe of pink *tulle*, fastened back on either side by bunches of pink hyacinths. The robe worn over a pink satin petticoat.

2. A robe of citron-colored *tulle*, tastefully trimmed with ribbons and bouquets of daisies.

3. Robe of sea-green *tulle*, open in front; a satin petticoat of the same color. This dress was worn with a beautiful *parure* of pearls.

4. A robe of lilac crape, trimmed with bunches of white lilac.

A new kind of satin has been introduced for promenade dress. It is very thick and richly figured, in patterns similar to those of the printed muslins. Green and puce are favorite colors; the pattern being a shade darker than that of the ground.

In carriage costume we have observed many bonnets of straw or citron-colored satin, ornamented with flowers or feathers of the same hue.

Velvet is the favorite material for promenade hats and bonnets. Blue, black and green are the colors most generally worn. A single feather placed on one side is the favorite ornament.

Aprons are now made of printed satin; the middle plain and of some light color, and edged round with a rich border, which is repeated on the pockets and the *ceinture*.

#### SUMMARY.

The President of the United States has recognized George Henrich Seimon as Consul of Bavaria for the port of New York; D. Manuel Valdez as Vice Consul of Portugal, for the port of Baltimore, and the State of Maryland; and Joao Vaughan has been appointed Vice Consul of Portugal, for the Port of Philadelphia, the other Ports of Pennsylvania, and the West Jersey.—[Nat. Intel.]

**EASY CHAIR.**—Mr. B. F. Hays of Massachusetts, has left at this office for inspection an easy chair, designed for the convenience of invalids. It is so constructed as to be used as a chair on rollers, or on rockers, and also as a cradle—or bed—and may be changed from one to the other, with great ease by the person using it, without rising.

It is a very ingenious, convenient and cheap article—and may be examined by all who desire to see it. M.

**EXPEDITION.**—The steamboat President, Capt. E. S. Bunker, arrived this morning in 14 hours and 9 minutes from Providence, being the shortest passage known considering the state of the tides.

From schools of the character of the one noticed in the following extract from the Albany Daily Advertiser, much good must certainly result. They will enable many a young man of talents to "work his passage" to eminence, who would, but for them, never dream—any more than did the honest planters of North Carolina—of the value of the mines beneath the surface of their native soil.

They should be cherished by every true lover of his country. M.

**Manual Labor School.**—We are happy to learn from the Columbia Republican that an institution, upon the plan of the Alabama school, will go into operation in Columbia County, in the early part of next month, with a good prospect of complete success. Ample funds; we believe, have been provided, so as to place the institution beyond the risk of embarrassment, the patronage and favor of a large number of gentlemen of influence, and religious societies has been secured, and the institution is placed under the directions of Rev. D. M. Smith, as Principal, a gentleman eminently qualified, by experience and education, to direct the *machinery* of so important a "department of benevolent operation."

A farm of 200 acres pleasant situation on the bank of the River, few miles above this city, has been purchased, and suitable buildings will be in readiness at the commencement of the 2d term; in the mean while, the farm house, sufficiently large to accommodate more than 50 scholars, will be occupied. The new buildings are to contain 64 rooms for students, a school room of large dimensions, and habitations for the teachers.

It is estimated that the expense for board and tuition at this school will not exceed \$75 per year, an amount which an industrious young man, by his labor for necessary recreation, say 3 hours per day, either at mechanical or agricultural labor, can earn.

**Uncurrent Money.**—The subject of adopting measures to require the Safety Fund Banks of the State to keep their bills at par in the city of New York, has been brought before the Legislature, and we cannot but think that a measure so evidently beneficial to the people will eventually be adopted. It is a notorious fact that the inconvenience and loss from uncurrent money are to business men very great; and as banks receive from the State Legislative sanction to issue notes as the representation of money, it is perfectly right and proper, and but even handed justice, that these notes be worth the face of them within the limits of the State, and that measures be adopted to require the banks issuing them to make them so.—[Troy Daily Whig.]

Much more benefit would result from the adoption of this measure, than from the prohibition of small notes.

Yesterday, at the Town Meeting, a communication from James Wadsworth, Esq. was read, stating that his late brother, Gen. Wm. Wadsworth, left by will, the sum of *one thousand dollars*, to be loaned on real estate, the interest of which sum is to be expended in educating the children of indigent parents in the town of Genesee. The Trustees of the several School Districts were informed that a quantity of School Books were left at the Clerk's Office, to be by them distributed as they should think proper.—[Livingston Register.]

[From the Jonesborough (Ten.) Republican and Jour.]

**DREADFUL TORNADO.**—One of the most violent hurricanes ever witnessed in this State was experienced in the lower part of Murray county, on the night of the 21st ult. Eight persons were killed and fifteen or twenty others, severely injured some of whom were not expected to recover, much damage has been done. Houses, fences, trees, and indeed every thing which opposed the progress of the winds has been swept away. Some idea may be formed of the force of the gale from the circumstance that a piece of poplar plank perfectly square and blunt at the end was found driven by the force of the wind, into the body of a lynn tree at an angle of about forty five degrees to the depth of 3 1-4 inches. It is said that the tornado visited the neighborhood of Clarksville on the same night with equal violence and accounts have been received of two deaths and two persons mortally wounded as is supposed. The foregoing particulars are taken from Columbia Observer, and we are apprehensive that the next accounts from the scenes of devastation will be of a most deplorable character.

Accounts from Florence Alabama represent that much injury was also sustained in the vicinity of that place though no lives lost.

Ice was made on Tuesday night in this city, and the surface of the ground frozen. Fortunately the fruit trees are not sufficiently forward to be injured by the frost, except possibly apricots, which are just beginning to blossom.—[Journ. of Commerce.]

The China and Fig trees in Georgia and South Carolina, have been generally killed by the severe weather of the past winter.

Among the passengers in the ship Francis Dupau, for Havre, which sailed on Saturday, was Professor Farnum, of Washington College, Virginia. Professor Farnum, we understand, is expected to purchase philosophical apparatus for that institution.

**Arrival of Dr. Jarvis.**—We are happy to announce that the Rev. Samuel F. Jarvis, D. D., has returned from his protracted residence abroad, and is at present in this city. The long absence of Dr. Jarvis has been for years a standing topic of regret. We are not apprized of his intentions, but we will not doubt that he purposes henceforward to pursue his labors for the Church in his native land, and in the midst of those friends who know and appreciate his distinguished learning and sterling worth.—[Churchman.]

**Bible for the Blind.**—At a meeting of the Blind School, Liverpool, on Friday week, Mr. William Brown presented to the institution a very handsome bound copy of a part of the gospel of St. Mark, printed in embossed letters, so as to be read by blind persons by the touch. It had been transmitted from the Blind Institution of Pennsylvania, by Mr. Richards, late Mayor of Philadelphia.—[Liverpool Advertiser.]

From the Buffalo Daily Advertiser we learn that a fine schooner, called the *Agnes Barton*, was launched from Carrick & Bidwell's Ship Yard, in that city, on Saturday. She is of a 110 tons burden, and owned by James L. Barton, Esq. This looks business like, and we hope to have frequent opportunities to record similar occurrences.

**LATER FROM ENGLAND.**—The ship Ontario, Capt. Sebor, arrived at this port last evening from London. She brings London papers to Saturday evening, March 21st, and Portsmouth to the 23d.

We are indebted to the morning papers for the latest dates.

The Portsmouth Telegraph of the 23d contains the following:—

"Sunday Morning, March 22.

The Bristol mail brings us intelligence that an American packet had arrived at Cork, with the news that *America has declared War against France.*"

The London Gazette announces that Lord Cowley has been appointed British Ambassador Extraordinary and Plenipotentiary at the Court of France.

It was reported that Sir Robert Cordon had been appointed ambassador to Russia.

Viscount Canterbury, his Majesty's Commissioner to Canada, to settle the disputes that have arisen there, was expected to embark for that colony about the 30th of April in a ship of war.

The Report of the Commissioners appointed to inquire into the state of the Established Church, was laid on the table of each House of Parliament on the 18th. It proposes a new arrangement of Dioceses, and adjustment of the incomes of the Bishops as nearly as may be, to their several stations and duties.

Sir Edward Sugden has suddenly and unexpectedly relinquished the Chancellorship of Ireland. Sir Charles Wetherell is among those spoken of as his successor.

An Action took place in Spain, March 12th, between Mina and Zumalacarraguy, in which the Carlisle were defeated at all points. The latter, however, had retreated to a commanding position between Pampeluna and St Sebastian.

The advices from Lisbon were to March 10th, at which time every thing was quiet.

A great fire occurred in the Chinese district of Macao on the 5th of November. It broke out in some boats moored near the river, which were destroyed, together with about *four hundred* well built houses.

**THE NEW YORK AND ERIE RAILROAD.**—For the information of persons disposed to subscribe on Wednesday, 15th, to the stock of this Company, we publish the following concise statement, from an authentic source, of the particulars of this great enterprise, destined, as we firmly believe, to become not less profitable than honourable to those of our citizens who may now concentrate their efforts and energies to carry the work vigorously forward.

[For the New York American.]

The attention of the public is earnestly invited to the following propositions:—

1. The construction of the New York and Erie Railroad will be practicable at a moderate expense.
2. It will become profitable to the stockholders as soon as 115 miles of single track shall be completed.
3. Every part of the road may be advantageously used for the transportation of persons and property.
4. The road, when completed, will open new and extensive channels of commerce to the city of New York, and will greatly add to its population and wealth.

I. The road is practicable.

It is 483 miles in length, and for more than 400 miles pursues the courses of streams. Railroads which go *with* the valleys of streams are cheap—those which cross them *transversely* are dear. The Mohawk and Hudson road, which does not follow

the streams, cost more than \$40,000 per mile. The Utica and Schenectady road, which follows the valley of the Mohawk, has been actually put under contract at less than 12,000 dollars per mile. That part of the Baltimore and Ohio road, between Baltimore and Ellicott's Mills, which crosses the valleys transversely, has cost upwards of 40,000 dollars per mile; and that part west of Ellicott's, which follows the valley of the Patapsco, has cost less than 15,000 dollars per mile.

The graduation of the Utica and Schenectady road, ready for the superstructure, is \$5728 per mile. That of the New York and Erie road, \$5626.

The cost of a single track of *superstructure* will vary according to the plan and materials, more or less imperishable, which may be selected. It will not be less than \$3000 nor more than \$5,500 per mile. That of the Camden and Amboy road between Bordentown and Camden was about \$4,700, that of the Utica and Schenectady, is \$4,950 per mile.

Assuming the most durable plan, the superstructure of the single track of the New York and Erie road will not exceed per mile, \$5,500  
And the graduation 5,626

11,126

The land required for the road bed, will, throughout at least nine tenths of the line, be gratuitously ceded to the Company.

Add for engineering and contingencies (per mile,) 1,374

12,500

Or for the whole 483 miles, \$5,637,500

II. The road will be *profitable* to the stockholders, and that too, as soon as one-section of 115 miles shall be completed,—after which its profits will rapidly increase, as that section shall be extended. From a point on the Delaware and Hudson canal, about 45 miles from tide water, the road can be completed to the great and fertile valley of the Susquehanna, (entering it at Bettaburgh,) a distance of 115 miles, for less than \$1,500,000. The population in the southern counties distant more than 70 miles west from the Hudson River, and whose products and supplies must be transported on the road, amounted to 338,846, by the census of 1830,—and had increased in the previous ten years at the rate of 55 per cent. [That of the whole of the canal counties, equally distant from the Hudson, and extending north to the northern boundaries of Jefferson County, was only 644,688, and had increased in ten years only 42 per cent.] Of this population of 338,846, at least 150,000 will commence using the road as soon as it reaches Bettaburgh.

From Bettaburgh the road can be extended west to Owego, 55 miles, at an expense of less than 700,000 dollars, and will there become connected through the Owego and Ithaca road, (now completed,) with the populous and fertile counties around and west of the Cayuga and Seneca Lakes.

It is found that the transportation on the Baltimore road has very rapidly increased since the line has been extended westward.

III. There are no grades of ascent on the road which will prevent its advantageous use for the transportation of persons or property.—Its grades are far less severe than those on the Baltimore road. Between Baltimore and Frederick there are the following rates of ascent:—One of 76 feet; one of 87; one of 176; and one of 253 feet to the mile; and yet the road is constantly used for the transportation of flour, live stock, provisions, granite, &c. many of which articles are actually taken out of the boats on the Chesapeake & Ohio Canal, at Harpers' Ferry, and carried in cars over the Railroad to Baltimore!

The severest grade on the New York & Erie Railroad (excepting the one inclined plane near Lake Erie) is only 100 feet to the mile—less than one half as steep as the branch of the Mohawk Railroad leading from the car-house at Albany up the street south of the Capitol. Locomotive engines on an improved plan have ascended with trains of passengers up a grade of 176 feet to the mile on the Baltimore road. Auxiliary engines, or an additional

of animal power.

er, can be cheaply employed, if found necessary, on the one ascent of 100 feet to the mile on the Erie road, and will not produce as much delay or expense as is experienced on the two inclined planes between Albany and Schenectady—or on the two inclined planes between Philadelphia and Columbia—or on the ten inclined planes on the Pennsylvania road over the Alleghany mountain, now covered with the merchandise of Philadelphia, moving to the far West.

On the New-York and Erie Railroad, besides this one ascent of 100 feet to the mile, there are two others of 70 feet,—one of 65 feet, and one of 61 feet—occurring at only *five points* on the whole line. The whole delay occasioned, either to passengers or the public mails at these five points, will not exceed two hours in the passage from New York to Lake Erie.

The rate of speed on more than nine-tenths of the road will be at least fifteen miles to the hour. Of the 483 miles, the grades of ascent on 329 miles are less than 20 feet to the mile: 416 miles are less than 40 ft: and only 23 miles exceed 60 feet to the mile.

On the Philadelphia and Columbia road there is one grade of 45 feet to the mile (beside the two inclined planes) laid down too over a quick—and constantly passed with locomotive engines. One of the grades on the Camden and Amboy road is more than 45 feet to the mile—and a part of the Liverpool and Manchester road exceeds that rate.

The country traversed by the road is salubrious, fertile and rapidly increasing in wealth. The valley of the Susquehanna occupied by the road, is upwards of 150 miles broad from east to west—and lies generally at an elevation of less than 1000 feet above tide water,—and less than 400 feet above the average level of the county of Ontario. The Pennsylvania Railroad over the Alleghany mountains, is upwards of 2300 feet above tide.

There are three great branches which will connect the main line with the canal counties—one, from Bettsburgh to Utica, about 73 miles; one from Owego 29 miles to Ithaca and Cayuga Lake; and one from Danville to Rochester, about 60 miles—whereby more than one half of the canal counties will be accommodated during the winter by railroads leading directly to this city.

The road being thus shown to be feasible at a moderate cost, and capable of advantageous use at all seasons of the year, it is claimed that,

IV. It will yield immense advantages, not only to the public, but also to the stockholders who may construct it.

The public will be benefited by its business; the stockholders by its revenue. The amount of its revenue will depend on the amount of its business. Its business will be created by the necessities of the population, who may use it, to transport their products and supplies to and from tide water.

The geographical districts, which it will accommodate, by furnishing to them a channel of transportation more cheap, regular, and desirable, than by any other avenue of trade or transport, consist of,

1. The southern or "railroad counties" of this State, including so much of the adjacent counties, as lies within 40 miles of the line of the route:—

2. The northern and central portion of Pennsylvania, adjacent to the Susquehanna, and capable of being reached by means of that stream, earlier than by the canals of that State:—

3. The southern, or Ohio division of the far West, watered by the Ohio river and its upper branch the Alleghany:—

4. The northern or lake division of the far West, lying around the upper Lakes.

The mere statement of these enormous masses of territory, which are thus to be rendered commercially tributary to the city of New-York, suffices of itself to demonstrate the magnitude, importance, and value of the proposed enterprise.—The whole state of New-York, west of a line 70 miles distant from the Hudson river, embracing an area of less than 24,000 square miles, contained, by the last census, only 983,534 inhabitants, and yet it paid in tolls to the Erie Canal during the last year upwards of a million of dollars.—[The whole amount of tolls paid for merchandise

going to, and coming from the States west of New-York, was less than 150,000 dollars.] What then will adequately measure the amount of revenue to be derived from the Erie railroad, which independently of its superior facilities for carrying passengers and the mail—of its unrivalled advantage of being available during the five months of the year in which the Erie Canal is closed,—will furnish the means of transport for

1. The Railroad counties, now containing 388,846 of the population of 983,534, thus paying the million of tolls to the State:—

2. The upper part of the Susquehanna valley and northern counties of Pennsylvania now numbering more than 100,000 inhabitants, and are rapidly increasing:—

3. The whole of the Ohio and Alleghany valleys embracing an area of 196,000 square miles, and already containing more than two millions of inhabitants:—

4. The vast and populous communities growing up around the great Western Lakes.

The immense commercial importance of the direct connexion to be effected by means of the proposed road and the Alleghany river, between the city of New-York and the Valley of the Mississippi, is but yet imperfectly realized or understood. Let it then be distinctly known to our merchants, that the moment the line of the Erie Railroad reaches the Alleghany river their merchandise can be delivered on its banks from their warehouses in this city, *within thirty-six hours!* that it can thence descend down the safe, though rapid, current of that stream, in less than two days to the wharves at Pittsburgh—that this navigation is always available precisely at the period when it is most needed, to wit, in the months of March and April, and that the river with small expense, can be rendered navigable throughout the whole summer and autumn. The enormous importance then of accomplishing this connexion, with the utmost practicable despatch, must then be evident. It is the only mode in which New York can neutralize the gigantic efforts making by Philadelphia to deprive her of the commerce of the west—but when completed, will most effectually accomplish that object. Pittsburgh will thence forward cease to be the western emporium of Pennsylvania, and with her long line of sister cities and communities along the valley of the Ohio, will become attached, as a commercial dependency, to this metropolis.

V. It can hardly be necessary to add, that the construction of this road, producing such mighty commercial results, and pouring into this mart of the Western world such gigantic streams of commercial wealth, must augment the population and riches of this metropolis to an almost incalculable extent. Since the Erie Canal was commenced, our population has increased from 120 to nearly 300 thousand;—our real estate from 54 to 123 millions;—our paved streets then terminating at Grand street, now reach more than half the distance to Harlem Bridge.

Can we then set any reasonable limits to the wealth, extent and grandeur of our city, when it shall quadruple its present commerce?—when its merchants shall sell merchandise worth 500 instead of 120 millions annually?—when the island of New York shall be covered throughout its whole surface, with warehouses and dwellings, and temples of religion, of science and the arts? when the mighty chain of railroads already commenced and rapidly spreading over the vast valleys of the West, and all converging towards Lake Erie, shall bring the whole countless population of those grand communities, within three days travel of the Atlantic sea board?

A NEW YORKER.

TRADE WITH THE WEST.—In as much as the Editor of the Albany Argus thinks that the "Philadelphians cannot be to grateful" to this paper for its "remarkable exhibition of liberality in shewing the advantages Pennsylvania possesses over New York, in early navigation," by "actually quoting from interior newspapers," a statement of facts, it may not be improper for us to continue occasionally, such statements as will enable our own citizens to know and appreciate the loss sustained by them—not only in this city, which loses the

sale of large amount of goods, but also in the country through which they would, under other circumstances be transported—by the actual and undeniable possession by Pennsylvania of those superior advantages for early transportation; and to the continuance of which superiority, in the hands of Pennsylvania, the Albany Argus, and its coadjutors with the honorable member from Utica, who, it is said, had so much compassion on the capitalists of this, city as to visit many of them personally, to guard them against the danger of loss by subscribing to the stock of the New York and Erie Railroad—have contributed so much, that it is now, *only* to be wrested from her by the united and determined efforts of the merchants and capitalists of this city—who must, and will, we are confident come forward and show the opponents of this measure, who are so from interested motives, that cupidity and selfishness cannot defeat it.

The following extract, from the Pittsburgh Gazette, shows in bold relief the importance and necessity of prompt and decided measures; and who so much, as the citizens of New York, are interested? Who to be so much benefited?—Will they rest easy and see the trade, which they have been accustomed to enjoy diverted to another city, simply because her forwarding houses will not forward goods purchased here, until those purchased there, are *first* all forwarded?—Or will they come forward and aid in constructing a work which will place them at least, upon equal terms? And by which the goods sold by them may be forwarded, when ready, without being subject to the veto power of any other city?—We shall see:

COLLECTOR'S OFFICE,  
Allegheny, W. D. Pa. Canal, April 4, 1835.  
Amount received in the week  
ending April 3, 1835, 694 59

51 boats cleared at this office, having tonnage, 1,058,873 lbs.  
Tonnage received from the East, 1,264,232 lbs.

Total tonnage of the week ending April 3, 1835, 2,323,105 lbs.

On what day of April will the Collector of Buffalo be able to make a similar statement?

Not that the people of Buffalo, or on the line of the canal have any object or interest in this delay. It is caused by *natural* obstacles; and, therefore, other means should be adopted; on the most approved mode, and the shortest and best route—and it is surprising that intelligent business men, who are liberal on other subjects, should be so short-sighted in relation to a work of this magnitude, after the experience which they have had of the incalculable benefits of such works.

Railroad from Portland to Quebec.—We observe by the Maine papers that Gov Dunlap has received from Lord Almyer, the Governor-General of British America, at Quebec, a letter, stating his readiness to co-operate with the authorities of Maine in the survey of the proposed route of a railroad from the Atlantic seaboard of Maine to Quebec. The Quebec people are stated to feel considerable interest in the measure, as it is natural to expect they would, for they are to look to this route as the most convenient and speedy outlet and inlet during a portion of the year.

The report of the Maine Legislature, upon the subject, made at its late session, had received the attention and met the approbation of the Quebec and Montreal people; and Lord Almyer, in compliance with public opinion, was ready to furnish a corps of Engineers, at the expense of the Government, to assist in procuring an accurate survey of the route and an estimate of the expense.—[Bost. Cour.]

## MISCELLANY.

**Our Revolutionary Navy.**—There is another branch of our annals which has been strangely neglected, and which is neither deficient in interest nor in material. We allude to our naval history. Every body has heard of Paul Jones and of Truxton; and every body knows by heart the achievements of Hull, Perry, Porter, McDonough, and Bainbridge; but the early and desperate conflicts of our revolutionary navy are, for the most part, forgotten, and by many were never heard of. Mr. Clarke, in his *Naval History*, and Goldsborough, in his *Naval Chronicle*, have alluded to these occurrences; but they have done so quite too summarily, though their works are valuable and accurate in recording the history of a later period. The gallant and bloody boat fights of Brewster, Hubbel, and Hawley, along the shores of Long Island Sound, where they encountered the Tories and British, are no where recorded, except in the memories of those who remain, and who participated in them. Among the facts recorded by Goldsborough, is that of a party of less than forty men, at Machias in Maine, who, when they heard of the commencement of hostilities at Lexington, took possession of a lumber sloop, and, armed with thirteen pitchforks, a few sabres, ten or twelve axes, and some pieces of salt pork, sailed in pursuit of a British armed schooner, (carrying four six-pounders, twenty swivels, two wall-pieces, with the proportionate armament of cutlasses, firearms, &c.) laid her alongside and, after a short and desperate engagement, carried her by boarding. With the guns and ammunition procured by this capture, they armed other vessels, and took many prizes. Several little fleets were fitted out from Boston and its vicinity, and cruised with success, and repeatedly succeeded against very superior forces. The achievements of Hopkins, Magford, Biddle, Williams, Waters, and Whipple, are unsurpassed for their cool intrepidity and good judgment. Mr. Clarke relates the following instance, which exhibits very forcibly the daring character, and adroit manoeuvres, of our naval warriors of that day:

“In June 1778, an expedition of United States vessels was fitted out and sailed from Boston.—It consisted of the *Providence*, thirty-two guns, Commodore Whipple; the *Queen of France*, twenty-eight guns, Captain J. P. Rathburne, and the sloop of war *Flanger*, Captain Simpson. About the middle of July, near the banks of Newfoundland, as the squadron lay in a fog, signal guns were heard, and at intervals the sound of ships' bells striking the hours. From this they supposed themselves to be near a fleet. About eleven o'clock the fog began to clear off, when the crew of the *Queen of France*, to their great surprise, found themselves nearly alongside a large merchant ship, and soon after they perceived themselves to be in a fleet of one hundred and fifty sail, under the convoy of a seventy-four, and several frigates and sloops of war. The *Queen of France* immediately bore down to the large ship and hailed her. She answered that the fleet was from Jamaica, bound to London. The English ship then hailed the American, and was answered, his majesty's ship *Arethusa*, from Halifax, on a cruise. The American then inquired if they had seen any rebel privateers. The English replied that several had been driven out of the fleet. The American, Captain Rathburne, then requested the English vessel to come on board, to his great astonishment. Capt. in of his own boat, and both well manned, to took quiet possession, alarm in the fleet, notice vessels were nearly surrounded. Rathburne then ordered the large ship, and captured.

Soon after the capture Commodore Whipple came on board. Captain Rathburne told him as soon as possible, as he was persuaded they would be discovered and overpowered. Captain Rathburne then pointed out the two large ships he had captured, and requested permission to remain. The Commodore at first disapproved of this project; but was at length prevailed upon by Captain Rathburne to

stay in the fleet all day, and capture as many vessels as they could, in the same cautious manner. As soon as it was dark they left the fleet, after having captured eleven vessels, without giving alarm. The squadron arrived safe at Boston with eight of their prizes—three of them having been retaken by the English.”

No man is more enthusiastic in attachment to their profession than the officers of our navy, and to none could the honorable task of recording its history and achievements be more properly confided. It is a work requiring careful accuracy and patient research, and we should have no difficulty in naming more than one of our naval friends who would add to these requisites, finished scholarship, and not unpractised pen.—[*American Monthly*.]

**The Wife of Queen Anne's Reign.**—The band of writers, who have rendered so illustrious the reign of Anne—Addison, Steele, Gay, Prior, Swift, Arbuthnot, Bolingbroke, Pope, and their associates, had, in 1735, been wasted and thinned by Time, whose step is alike unerring, and whose scythe is equally unsparring in every age. Gay died when his celebrated comedy began to remunerate him for his previous misfortunes.—Steele—the careless, yet magnanimous Sir Richard—was no more. Arbuthnot—the mitred Rochester—had expired in unmerited exile.—The gentle spirit of Addison, who had taught his contemporaries how to live, had also (in the beautiful language of his eulogist) “taught them how to die.” Arbuthnot—the witty, the humorous, the learned and generous Arbuthnot—was sinking under the disease, that rendered “Rathburne,” as he said, the only wish his friends should prefer for him. Bolingbroke had passed through the extremes of his eventful life. Parliamentary influence—oratorical fame—official power—the imminent self-kill and compulsory exile were over, leaving him thenceforth to affect philosophy, and nourish personal and political malignity, and assiduous religion. The stern intellect of Swift, preserved as yet, its masculine force; but savage misanthropy had become its absorbing sentiment, and prevent shadows announced the approach of the dark disease, which ultimately rendered this scourge of mankind, himself “a driveller and a shew.”

Pope, however, remained in the meridian of his life—in the blaze of his fame—in the full exercise of his power. Having impaled the whole host of the dunces, with the shafts of his satire, he was now moralizing his song, and giving to the world his *Essay on Man*.

The lapse of a century, constitutes us, perhaps, the posterity to whose judgment these writers are often appealed; and if the respective present popularity of these authors, be the true test of their merits, their relative station has been indeed much altered by time. Steele has dropped entirely out of public view. Prior has grown obscure in the distance. Since the taste of our day has endured the revival of highwaymen's exploits, and tolerated the brutal slang of the bride-well, and the bawling, there seems no reason why the *Beggar's Opera* of Gay, should have gone into comparative obscurity, while Paul Clifford, and Rockwood, without a tinge of its wit, or an atom of its verisimilitude, find numerous admirers.—Captain Macbeth has no mawkish sentiment, nor improbable refinement, nor impossible manners; and his careless prodigality, and sparkling wit, with “his pistol that never misses fire, and his mare that never slips a shoulder,” might render him a classical regus. We fear our favorite Arbuthnot is not read as he ought to be. His “History of John Bull” has been imitated and traversed so often, that we forget the happy conception of the allegory, and the merit of its execution; and Marianne Scriblerus has not so many disciples as he ought to have.

There is a beautiful halo around the name of Addison. We think of him as a being of gentle manners, and attractive morality, and graceful piety; but his reputation for genius is not what it was, a hundred years ago. His *Ca'u* is preserved from utter oblivion, only by our school-boys, who declaim the stoic's dying speech.—Two little hymns are all that is popular of his poetry. The infinite expansion of periodical literature, in the last twenty years has thrown the *Spectator* into the shade. But *Sir Roger* de

Coevery will be immortal. The representative of a class of men, who have passed away, and of a mode of life which will never exist again; the delineation of refined simplicity—of gentle civility—of amiable, and not unnatural eccentricity—he will be admired, when the portraits of Kneller shall have mouldered, and for ever preserve the name of his delineator from oblivion.

On the remaining triumvirate of harder nature, and loftier genius.—Pope, Bolingbroke, and Swift—the effect of time has also been unequal. He, to whom the others deferred—the titled author—has tared the worst. His political writings have sunk into annihilation. On reading his “*Patriot King*,” and “*Thoughts on Exile*,” we ask with wonder, what could so acute a critic as Chesterfield find in their rapid and pointless verbiage, to recommend as models to his son? More subtle shapess, and bolder infidelities, have crowded his philosophical wrangles into the obscurity of the most cob-webbed shelves of our libraries.—And when another century shall have revolved, the “all-accomplished St. John” will perhaps only be known by the verse in which Pope affected to ask for himself, no other future recognition than as the dependant upon his “*Guide, Philosopher, and Friend*.” But why has Swift, whose burning sarcasm, and poignant wit, and piercing argument, and vigorous style, have no superior in the whole circle of English literature, also subsided from his eminence of fame? His “*Tale of a Tub*,” is not read. His “*Conduct of the Allies*,” which upheld a ministry, is forgotten. His “*Drapier's Letters*,” which made him the O'Connell of the day, are buried in obscurity. “Where be your gibes now! your gambols? your songs? your flashes of merriment?”—The answer ranges in, that human feeling has avenged the outrage upon itself; and he, who could find in his fellows, nothing to love or admire, is for that reason, with all his genius, deprived of the love and admiration of his kind. It is by the writings of Alexander Pope, that the lighter literature of England, in the beginning of the past century, chiefly exercised influence on the present. His writings have stood the test of time. The monument of his fame is “a solid fabric, and will support the laurels that adorn it.” The controversialist, who would point a period, resorts to his satires. The philosopher, who would clothe an apothegm, borrows from his essay.—And—what perhaps is the highest praise of all—his lines, his sparkling phrases, have passed into the current language of the day, and become household terms.—[*American Monthly*.]

**Increase of Law Books.**—About 1717, Dean Swift, in one of his pamphlets, remarks “the great increase of law-books,” and asked, “what would become of lawyers, if their libraries kept on increasing for a century, at such a rate?”—Law books have kept on increasing, in more than a geometrical ratio, and of their increase there is no end. The Dean's question was a sensible one, and seemed to admit of no answer. Neither did his question as to what posterity would do with the national debt of England, which then amounted to fifty millions sterling. But the course of human events is more incredible than fiction, and inscrutable to human philosophy.

When Swift's inquiry was made, Blackstone had not written and Mansfield had not deceased.—Since then, the Parliament of England has been pouring forth laws, regularly as the course of the seasons, and copiously as the autumnal harvests. These are in the lawyers' library.—Since then, the Court of Chancery, which, grim as Cerberus, met the hapless adventurer in the caverns of the law, has, like that gentleman, (as Mrs. Malaprop called him) been divided into three heads—viz. the Vice-Chancellor—the High Court of Chancery, and from each have been gathered volumes;—and these are in our lawyers' library!—The king's Bench—the Common Pleas—the Exchequer—the Doctors' Commons—the Admiralty—have, for a hundred years, been shedding edicts, numerous as the Sibyl's leaves, and equally lucid—but, alas! not scattered like hers, but bound in calf-skin books—and there are in our lawyers' library!—But this is not all. On this side of the Atlantic, four-and-twenty legislatures, all in a row, are annually, like so many grist-mills, grinding forth laws; and one or two, three, or four judicial tri-

books in each State are, every year, publishing their decisions, to be bound in yellow leather for the lawyers' library.

Patron reader! we are not through yet. The Bar partakes the mania of the Bench. Scribbles, and indolence. Essays and treatises, and criticisms, and strictures, and arguments, have been every year extorted from its wearied press, in numbers that would frighten Magistrate himself; yet most every lawyer have these in his library!

We postpone to some other time, all remarks on the wisdom and benefit of the legal system; our object being merely to show in this respect, the contrast of the present and the past century; but what would the Dean of St. Patrick say to the prodigies, to which we have feebly alluded? He would probably acknowledge that the imagination which conceived the idea of Brobdingnag, was inadequate to comprehend the magnitude of the legal science: or, were probably, he would add a chapter to his Voyage to Laputa, and place our law-makers, and law-expounders, by the side of those useful philosophers who discovered and practised the wondrous art of extracting sunbeams from cucumbers.—[American Monthly.]

**Submarine Volcanoes**—are those which break out from the bottom of the sea, and which, being their lava higher and higher, sometimes gradually, and at others instantly, raise islands, where before nothing obstructed the billows of the ocean. They are preceded by violent agitations of the water, and the discharge of gas, smoke, and vapors; they are often on fire, and roll and sweep in fearful whorls of flame over the waters. Stones are cast up—the crater often peeks above the surface, and either remains after the eruption has subsided, or sinks again into the abyss. The volcanic islands, generally, are supposed to have been raised from the bed of the ocean in this way. A soil ultimately accumulates upon them, and the decomposition of the lava itself, gradually furnishes sufficient for vegetation. A great number of islands have been cast up in this manner, within comparatively a few years. Most of them have again sunk, though some remain. Dr. Webster, to whose work we have before referred, gives a full account of that which rose near St. Michael, in the Azores; and one which appeared in the Mediterranean in 1831, is described in a very interesting manner by Dr. DeKay, in his work recently published.

Such has been, doubtless, the origin of many of the islands of the Atlantic and Pacific. In the Grecian Archipelago, very many of the islands bear strong marks of volcanic action. The same is true of the Canaries, Tenerife, the Cape de Verde, the Luperi islands, the Azores, Adenion island, St. Helena, the Isles of France, and Bourbon, the Aleutian islands south of Bering's straits, the Kurils, the Philippines, or Sandwich, and other immense ranges occupying the Pacific and Indian oceans. In the West Indies, Trinidad, Granada, St. Vincent, St. Lucia, Martinique, Dominica, Guadeloupe, Montserrat, Nevis, St. Eustatia, and many others, all give unquestionable evidence of their ancient volcanic character and origin.

Captain Basil Hall, who is perhaps better authority on the subject of volcanoes than of republics, states the Loo-Choo islands, in the China Sea, to be volcanic in their origin; and that he saw one peak just rising above the water, which had every appearance of an extinguished crater.

**The Volcanoes of Mexico.**—In Mexico, a chain of volcanoes traverses the country from east to west, being at right angles with the great range of mountains which runs through it; that of Texila, near Vera Cruz, had an eruption in 1793, and the ashes were carried upwards of one hundred and seventy miles. West of this lies Orizaba, seventeen thousand three hundred feet high, and Popocatepetl, seventeen thousand six hundred feet high—being the greatest elevation in Mexico. It has been in action for three hundred years, but has emitted nothing more than smoke and ashes. On the west of the city of Mexico is the volcano of Jorullo and Colima, and a vast extent of the plains beyond give evident indication of volcanic fire beneath their surface. Humboldt, in speaking of these plains, says that "in the month of June, 1799, a subterranean noise was heard. Hollow sounds, of the most alarming nature, were accompanied by frequent earthquakes, which succeeded each other from fifty

to sixty days, to the great consternation of the inhabitants; for about a month all was again quiet, when on the night of the 28th September, the horrible subterranean noise recommenced. The affrighted Indians fled to the mountains of Agassaron; a tract of ground, from three to four square miles in extent rose up in the shape of a bladder. The bounds of this convulsion are still distinguishable from the fractured strata."

Those who witnessed this great catastrophe from the top of Agassaron, assert that the flames burst forth over a surface of more than half a square league; that fragments of burning rocks were thrown to a prodigious height, and that through a thick cloud of ashes, illuminated by volcanic fire, the softened surface of the earth was seen to swell up like an agitated sea. The rivers of Orizaba and San Pedro, precipitated themselves into the burning chasms; the flames were rendered more violent by the decomposition of this water, and were visible at an immense distance. The whole surface is now covered with thousands of small cones, from six to ten feet in height, called by the Indians cones, from which heated vapors ascend to the height of from twenty-two to thirty-two feet.—[American Monthly Magazine.]

**Patriotic Liberty.**—We have great pleasure in communicating the fact, that Lieut. Burnes, the intrepid and enterprising traveller, has just presented to the trustees of the British Museum the whole of the coins collected by him in the course of his travels into Bokhara. They consist of upwards of two hundred Bactrian, Indo-Grecian, Indo-Scythic, Hindoo, and Muhammedan coins. In short, the collection is unique. An especial vote of thanks from the trustees has been given to our gallant countryman for his splendid donation.

**Epidemics.**—This pestilence, so fatal to cattle, has ravaged Moravia and many parts of the Austrian empire with extraordinary mortality. In many places whole herds have perished. Would not the investigation of its cause be a subject worthy of the best attention of our various scientific institutions—medical, botanical, entomological?

[From the American Monthly Magazine.]

TO—

I left thee—not did seem to grieve—  
I breathed no aid nor wild farewell;  
But ah! more deep, more keen, believe,  
The grief I rush'd not how to tell.

all.

oh.

Oh then, would, thou wilt not dream  
Under the pang such partings bring—  
Must swift the tide when calm the current,  
And sudden glide but rarely sleep.

M. L.

# RAILROAD CASTINGS.

MINT & WARD, Proprietors of the Albany Locomotive and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads.

Albany, N. Y.

# PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to leak water.

Orders may be addressed to Messrs. SEASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y.

Sept. 15, 1837

# RAILWAY IRON.

25 tons of 1 inch by 1 inch, Flat Bars in lengths of 14 to 18 feet, counter sunk holes, cut at an angle of 45 degrees, with 1/2 inch plates and nails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, bolts and pins.

Wrought Iron Rails of 22, 24, and 26 inches diameter for Wheels of Railway Cars, and of 30 inches diameter for Locomotive wheels.

As also of 24, 26, 28, 30, 32, 34, and 36 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Government and Incorporated Governments, and the Drawback taken in part payment.

A. & G. RALSTON.

8 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them.

Albany, N. Y.

# STURGEONSHIP.

Builder of a superior class of Passenger Cars for Railroads.

No. 208 Elizabeth street, near Blocher street, New-York.

RAILROAD COMPANIES would do well to examine these Cars, a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation.

J. J. H.

# RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fixed to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

JO ROGBLS, KETCHUM & GROSVENOR

# NOTICE TO MANUFACTURERS.

SIMON FAIRMAN, of the village of Landingsburgh, in the county of Monmouth, and state of New-York, has invented and put in operation a Machine for making Wrought Nails with square points. This machine will make about sixty six nails, and about forty two nails in a minute, and in the same proportion larger sizes, even to spikes for ships. The nail is hammered and comes from the machine completely heated to redness, that its capacity for being clenched is good and sure. One horse power is sufficient to drive one machine, and may easily be applied where such power for driving machinery is in operation. Said Fairman will make, vend and warrant machines as above, to any persons who may apply for them as soon as they may be made, and on the most reasonable terms. He also desires to sell one half of his patent rights for the use of said machines throughout the United States. Any person desiring further information, or to purchase, will please to call at the machine shop of Mr. John Humphrey, in the village of Landingsburgh.

August 15, 1837.

AM & RM & F

# SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

K. & G. W. BLUNT, 134 Water street, corner of Market lane.

J. J. H.

# SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, to principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Chronometer, with two Telescopes—and a Leveling Instrument, with a Clinometer attached, particularly adapted to Railroad purposes.

W. J. YOUNG,

Mathematical Instrument Maker, No. 9 Dock at, Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

Baltimore, 1837.

In reply to the inquiries respecting the instruments manufactured by me, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish the following information. The whole number of Levels now in possession of the department of construction of the Baltimore and Ohio Railroad are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repair, except from accidents to which all instruments of the kind are liable.

I have found that the patterns for the Levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Compasses that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a traversing telescope, in place of the vane sight, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLER, Supr of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1838.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germanstown, February, 1838.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY B. CAMPBELL, Eng. Philad.

German and Norristown Railroads.

**Schuylkill Canal.**—During the week ending April the 7th, 1834, the amount of toll received on this valuable work was \$2,191 68.—During the present season the Canal opened on the 17th of March, and the receipts of the toll for the week ending the 3d inst. amount to \$9,722 04, or more than four times as much as during the same period of the preceding year.—[Philadelphia Commercial Herald.]

**Union Canal.**—This important link in our great chain of internal improvements, opened for the season on the 19th ult. and is now in excellent navigable order. The best evidence that we can furnish of the prosperity of this work, is to state that during the week ending the 31st inst., the amount of toll received was \$4,536 65.—[Philadelphia Commercial Herald.]

**Arrival from Pittsburg.**—Yesterday the Canal Boat, Sarah Tiers, belonging to the Pittsburg Transportation Line, arrived at their Warehouse, Chestnut street wharf, Schuylkill, freighted with a full cargo from Pittsburg; being the first arrival this season by the Canals and Railroad.—[Philadelphia paper.]

• There is a very spirited competition between the Railroad and the new line of stages established by Stockton and Stokes on the Turnpike Road between this city and Baltimore. We now get the Baltimore newspapers several hours earlier by the stages than we have heretofore received them by the cars. The Railroad Company have brought one of their "big tea-kettles," over the Ridge, and intend, we understand, to employ steam on the whole road between Frederick and Baltimore.—[Frederick, M. D. Examiner.]

[From the National Intelligencer.]

TO THE EDITORS.—Gentlemen: I am sure that it will be very acceptable intelligence to many of your readers to know that the Engineer reports, the completion of the Chesapeake and Ohio Canal to a point eight miles above Williamsport, (being 110 miles from this city,) so far as to open it for trade.

Sixty boats, loaded with Flour, Coal, &c., had descended the Lock below Williamsport, and forty more were about to pass that point on the 9th inst. So that, if no accident should occur to the new work below that point, we may in a day or two hope to see some of this produce of the Allegany Mountain at our doors.

Washington, April 11.

**Richmond and Potomac Rail Road.**—The Whig of yesterday states, on the authority of one of the directors of this work, "that notwithstanding the severe and protracted winter, the work is progressing well. The earth work is getting in a considerable state of forwardness, and the bridges and culverts, some of which are already begun, will soon be in an active state of progression. In most places, good quarries of suitable stone have been found where they were wanted. for the superstructure has p. is yet down, and much of and put along the line where at some unforeseen hindrance, probably be on 25 or 30 miles of Dec. next.—Compiler.

**The Railroad.**—All is complete to the Not-toway, except the laying down of the iron rails, which is progressing at the rate of a mile a day, and the road will be ready for the passage of cars to that river by the first of May, when 43 miles

will have been finished. The bridge across the Nottoway is nearly completed.—[Norfolk Her. ald.]

**James and Kanawha Improvement.**—The Second Auditor gives notice that 32,123 shares of the stock of this company have been subscribed for, by individuals and body corporate and political, either than the commonwealth, and that the President and Directors of the James River Company will proceed on the 1st day of May next, to ascertain the amount of valid subscriptions—that is the subscriptions, upon which a payment of one dollar, per share, has been paid, pursuant to the act of 20th February last.—[Arona.]

**Something New.**—The Pittsburgh Gazette notices, under the above head, a machine lately invented and put in operation in the Northern Liberties of that city, for preparing stone for M'Adamized roads. That paper says, the machine is simple and substantial in its structure, and very expeditious and powerful in its operation. It adds on the authority of Mr. Davis, the inventor, that two men and two boys could do as much work with the aid of this machine, as ten men working in the usual manner. It may be worked either by steam or horse power. The Gazette observes in conclusion. We think that Turnpike or M'Adamized road companies in the country would find great advantage in the use of this machine.

RAILROAD JOURNAL AND ADVOCATE OF  
INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, IN ADVANCE. Previous volumes same price; full set of four volumes, \$12.

RAILROAD AND CANAL MAP,

Or a Map of the United States, 34 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$3.

MECHANICS' MAGAZINE, AND REGISTER OF  
INVENTIONS AND IMPROVEMENTS.

This work has completed 4 volumes, or two years. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, IN ADVANCE. Previous volumes \$1.50 each.

THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 25 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

• All letters must be postage paid. Eleven numbers sent to one address for \$5.—and TWENTY-THREE for \$10. D. K. M.

NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 2d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Volumes 8 and 7, or 1 and 2, new series, \$3 per volume.

QUARTERLY JOURNAL OF AGRICULTURE,  
MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of

the three preceding works; its character may therefore be understood by reading these advertisements. It has been published at \$3, but will be, hereafter, at \$4 per annum—always in advance, each quarterly number to contain about 220 pages.

These works may all, or either of them, be had of R. Blydenburgh, 95 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Farnenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,  
25 Wall street, New-York.

GOLD REGION OF THE UNITED STATES.

• Now in press and will be published in a few days the first of a series of numbers, giving a minute and particular description of the entire Gold Region of the United States.

Each number will be accompanied by a Map, on which will be laid down, and numbered, with owner's name, in the order of discovery, of every Gold Mine within the district of which the number treats, so that any person can ascertain the location, owner's name, and condition, at least as January 1, 1838, of every Gold Mine, or place where gold has been discovered in the United States.

The first number, which will be issued by the 25th of April, will give the Gold region of North Carolina; together with a very interesting Essay, upon the Gold region of the United States, from the transmission of the Geological Society of Pennsylvania, by James Watson, Esq., F. G. S. of London, C. M. G. S. of Pennsylvania, &c. &c.—With other interesting and important information in relation to the supply and consumption of Gold.

The information and maps are by a gentleman, who has visited personally what he describes.

No. 2, including the States of Virginia and Maryland, will be published by the first, or during the month of, June.

No. 3, giving Pennsylvania, New Jersey and New-York, by the first of August. And the succeeding numbers, 4 and 5, which will probably complete the series, by the first of January next.

The terms will be \$1 per number, or \$5 for the Series.—Subscriptions addressed to D. K. MINOR, or to the publishers, T. & O. WOOD.

No. 7 Wall street.

• Gentlemen who may have particulars, or details, of present condition of mines in North Carolina, will oblige me by communicating the same, that the work may be as complete as possible. D. K. MINOR.

MILL DAM FOUNDRY FOR SALE.

• The Proprietors of the Mill Dam Foundry offer for sale or lease their well known establishment, situated one mile from Boston. The improvements consist of

No. 1. Boiler House, 50 feet by 30 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. Blacksmith's Shop, 50 feet by 30, fitted with cranes for heavy work.

No. 3. Locomotive House, 54 feet by 33, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with slate, 150 feet by 60, containing two water-wheels, equal to 60 horse power, Machine Shop, fitted with lathe, &c. Pattern Shop, Rolling Mill and Furnaces, capable of rolling 4 tons of iron per day, exclusive of other work; three Trip Hammers, one of which is very large; Engine for blowing cupola Furnaces, moved by water-wheel, one very superior, 8 horse Steam Engine, which could be displaced with a variety of other machinery.

No. 5. An Iron Foundry, 50 feet by 45, with a superior air Furnace and two Cupolas. Core oven, Crucible, &c. fitted for the largest work. Attached to the Foundry is a large ware-house, containing Patterns for the Castings of Hydraulic Presses, Locomotives and other Steam Engines, Lead Mill Rolls, Gearing, Shafts, Boilers, Gears, &c. &c. These were made of the most durable materials, under the direction of a very scientific and practical Engineer, and are supposed to be of great value.

No. 6. A building, 65 feet by 35, containing a large stock of chimneys, and furnaces, for making Cast Steel. This building is at present used as a boarding house, and can accommodate a large number of men.

No. 7. A range of buildings, 300 feet long by 35, containing counting room, several stores, rooms, a Steam Foundry, room for planing castings, a large loft for storing patterns, stable for two horses, &c. &c.

The above establishment being on tide water, presents greater advantages for some kinds of business than any other in the United States. Coal and iron can be carried from vessels in the harbor of Boston, to the wharf in front of the Foundry, at 25 to 30 cents per ton. Some of the largest jobs of iron work have been completed at this establishment, among others, the great shaft and lift pumps for raising the dry dock at the Navy Yard at Charleston.

The situation for Railroad work is excellent, being in the angle formed by the crossing of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at this Foundry. With the Furnaces and Machinery now in the premises, 15 Locomotives and as many tenders, besides a great quantity of cars and wagons, could be made per annum.

For terms, apply to

THOM. J. BECKLEY, Trustee, &c., Boston, or to ROBERT BALSTON, Jr., Philadelphia. Boston, Dec. 22, 1834.

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, APRIL 25, 1835.

**CANAL NAVIGATION.**—As speed in travelling has become, to business men, at least, a matter of much importance,—and as an increased rate of travelling is so desirable on our canals, and may so easily, as we are satisfied, be attained,—we shall give at length in the Journal, a work on “Canal Navigation—the resistance of water to boats upon canals, and other bodies of water; being the results of experiments made by John MacNeil, Esq. M. R. J. A., Member of the Institution of Civil Engineers, London.”

This work gives plans and descriptions of the iron boats which have been, and are now, in use on canals in Great Britain—especially on the Androsian, or Paisley Canal, on which the ordinary speed has been, for nearly two years, from nine to ten miles an hour, without injury to the canal banks, although 12 to 14 passages were made per day.

The wonderful performances on this canal, and the contradiction of previous received theories, as regards the resistance of fluids at high velocities, will be productive of immense benefits to this country, where canals are so much in use.

Baron Thierry of Panama has addressed a memoir to the President of the republic of New Grenada on the subject of connecting the Atlantic and the Pacific. The Baron prefers a canal to the contemplated railroad, and pledges himself to complete one within two years.

## Railroad Locks.

To the Editor of the Am. Railroad Journal:

SIR,—The frequent impracticability of excavating mountainous tracts, and the danger, expense, and inconvenience of inclined planes and stationary steam engines, have compelled engineers to pursue the valleys of streams in locating routes for railroads. That method, while it greatly extends the distance, cannot in all cases obviate the necessity for planes; and though it may diminish their number, is objectionable on principles of expedience and economy. It is questionable, whether the public would not rather encounter some hazard from an elevating power, than be subject to the expense and delay incident to travelling and transportation over the increased distance of a meandering course, however willing they might be to sacrifice either time or expense, to secure safety and the abolition of inclined planes and stationary steam power. One, and the principal object, of inclined planes on railroads intended for passengers and forwarding articles of commerce, is diminution of distance, and if that can be accomplished by locks, with more security and less expense, the loss of time in ascending elevations will be of little consequence.

It is not contended that locks equal the speed of inclined planes and stationary steam power in ascending, but it will be shown that long routes can be performed in less time, with locks to overcome heights, than by winding round their base and pursuing the valleys, and at much less expense. The importance of this view, in the economy of locks, depends on the formation of the country through which a railroad is laid, as the difference in the distance of a route over the acclivities and one shunning them will be governed by the number and magnitude of the elevations.

In case the increased distance of a “serpentine course is very considerable” compared with the extent of the whole line, and the excess of time to perform the route by locks inconsiderable, the benefit community would derive from constructing the New-York and Erie Railroad with locks, is too obvious to require much comment. By referring to the survey of that road some idea may be formed of the economy of locks. Allowing only 40 miles increased distance for the “serpentine course, to obtain easy grades of acclivity,” and that a very expensive plane must be constructed,

the diminution of that distance (equal to one ninth of the length of the Erie Canal) in travelling from New-York to Lake Erie, would be an immense saving to the public, without reference to transportation.

The advantages of locks on railroads are not confined to the public; the stockholders, as individuals, derive two important benefits from their use. Stationary steam engines are dispensed with, and the locomotive ascends with the train. It is the heavy annual expense of stationary steam power and appendages on inclined planes, and the great inconvenience of detaching the locomotive from the waggons in ascending, that renders distance so preferable to railroad companies, when distance will obviate the necessity of planes. W. G.

**Black river Canal.**—The committee of the Senate have made a long report upon the subject of this Canal.

“The report acknowledges the importance of the project, but, owing to the exhausted state of the Treasury, and the various improvements already authorized, the committee express the opinion that the bill authorizing the construction of this Canal, ought not to pass.”

**Mad River and Lake Erie Railroad.**—The Urbana Record, of the 4th inst., says that the directors of this work met at that place, on the 1st inst., for the purpose of devising means for its commencement.

They resolved to commence the work at its northern extremity, on or about the 1st of June, and to prosecute it vigorously until completed.

The northern termination is at Portland, or Sandusky city, on Sandusky bay.

The Indianapolis Journal, of the 3d inst., states that the Canal Commissioners have determined (no unforeseen providence preventing) to complete thirty-two miles of the Wabash and Erie Canal, from Fort Wayne to Huntington, by the 1st of June.

These improvements all tend to increase the amount of commerce which will shortly pass over Lake Erie, and to enhance the importance of a connection with that inland sea.—[Pittsburgh Gazette.]

**Canals in Illinois.**—A bill has passed both branches of the Legislature of this State, for the construction of a canal from the Illinois river to Lake Michigan. The improvements, when completed, will be 115 miles in length, and will open a direct communication between the Lake and New Orleans, and the river St. Lawrence and Gulf of Mexico. The estimated cost of this work is \$3,000,000.—[National Intelligencer.]

*Report of Frederick C. Mills, Engineer, to the Honorable the Canal Commissioners of the State of New-York.*

(Continued from number 15.)

**PROBABLE REVENUE.**

In regard to the probable amount of revenue that may be derived from the Rochester and Olean canal, I would remark, that the opportunity afforded and the time allowed me since I learned the wishes of the Commissioners upon that subject, have been too limited to enable me to furnish them with as full and perfect an estimate as I could wish. The importance of this matter would seem to demand the institution of the closest inquiry into the resources and want of a district embracing the amount of population that would naturally be dependent upon the canal, with a detail of facts relating to the imports and exports, and the capacity of the country for tending her improvements in agriculture, and in all the various branches of art and manufacture, and also the probable amount of freight which would make use of this channel in passing to and from the Ohio river. To perform all this in a satisfactory manner, would require more time and attention than I have been able to devote to it; but that you may be aided in forming an approximate estimate, I will briefly present for your consideration the following facts collected from personal observation, and from residents on different parts of the route, as the most correct view I am able to give of the subject.

An account was taken of the quantity of timber rafted down the Allegany river during one year, including the towns bordering on the Ischua, Oil, and Olean creeks, and that portion of country lying upon the head waters of the Allegany river, both in this State and in the State of Pennsylvania. The amount was found to be 100,000,000 of feet. The towns upon the Genesee river, above the confluence of Black creek, are generally well timbered, and but a very small portion has found its way to market, for want of a channel thereto. This whole district abounds with sites for saw-mills, which it is supposed would be occupied so soon as an avenue to market for their products should be opened. Besides the above, it is supposed by some gentlemen residing in that section, that one hundred million feet of lumber would be manufactured annually on the completion of the canal. Others consider this amount much too large, and upon comparing the opinions of different persons consulted on the subject, I am led to believe that 22 millions of feet will, in all probability, be manufactured in the region, embracing the district of country from the head waters of the Genesee river to Mount Morris. Within a short distance of Dansville are now 55 saw mills, from which, and from the different towns between Dansville and Scottsville, 8 millions more may be calculated upon. For safety, let us assume that the total amount of lumber annually manufactured would be 117½ millions of feet. The average cost of rafting lumber down the Allegany river to market is \$3½ per 1,000 feet, and it brings when in market, from \$5½ to \$14 per 1,000 feet, which, if we allow \$9½ to be the average, would leave, (after deducting the expense of rafting,) \$6 per 1,000 feet for the manufacturer. The retail price at the mills is about \$5½.

Of the lumber cut in Oswego county, which lies 195 miles from Albany, by the Erie and Oswego canals, more than three fourths is sent to market, and is rated as follows, viz:

	per 1000 feet.
1st quality, . . . . .	\$30
2d do. . . . .	20
3d do. or merchantable, . . . . .	15
4th do. or culls, . . . . .	10

At the rate of toll, during the last year, the price of transportation from Fulton, on the Oswego canal, to Albany, (a distance of 195 miles,) was \$4½ per 1,000 feet; from the head of Seneca lake, a distance of 265 miles, \$6½; and from Rochester, a distance of 270 miles, \$6½. Hence the average cost of transportation of sawed lumber, by the Rochester and Olean, and Erie canals, will not exceed \$9 per 1,000 feet. From the statement of rates in Oswego county, it is apparent that one third of the lumber cut on and in the vicinity of the Rochester and Olean canal, might be advantageously transported thereon to the Erie canal, and thence to Albany; but as a portion of the lumber estimated must come from Pennsylvania, and from the borders of the Allegany river for some distance below Olean, and as the opening of this channel will, in all probability, create a competition between the eastern market and that upon the Allegany river, and the Ohio, it is reasonable to conclude, that not more than one fifth of the whole amount will pass by this channel to the Erie canal, equal to 19,500,000 feet b. m., which, averaging a distance of 70 miles through the R. and O. canal, will amount, at 8 mills per 1,000 feet per mile, to \$10,920.

Although the counties of Cattaraugus and Allegany possess a considerable share of arable and fertile land, yet but little exertion has been made to raise greater crops of grain than are sufficient for home consumption; but little revenue could therefore be expected from this branch of trade, under present circumstances; but the inhabitants of these counties are generally of opinion that the opening of the canal would give a great impetus to this branch of agriculture, and that it would form a sure and gradually increasing source of trade, which would probably make up the deficiency in the revenue, which would take place when the timber becomes more scarce. Some pains have been taken to ascertain the precise amount of wheat raised in Livingston county by residents there, who have furnished me with the information which they have collected. They state that one million of bushels are annually raised there, of which it may be presumed a large proportion would pass through the canal. Two or three of the extreme eastern towns of Livingston county send their produce directly to the Erie canal; but the deficiency, will be supplied by the towns of Perry, Covington, and others in Genesee county; and it is believed the annual amount may be safely estimated at 650,000\* bushels, averaging 35 miles of distance, upon the canal, which at the present rate of toll, would amount to \$6,142.50. Of the probable amount of other agricultural produce which would find a vent through this channel, no data could be obtained from which any certain inferences might be drawn. I am, however, assured that much larger quantities of produce than sufficient for home consumption, such as butter, cheese, lard, pork, tallow, &c. &c. can and would be produced so soon as a communication is opened to a market for its disposal. In addition to these, pot and

pearl ashes would pass by this route from the counties of Steuben, Allegany, and Cattaraugus, which would be supplied in return, as well as a tract of country bordering the Allegany river, with lime, gypsum, and salt.

There is in this district some timber which would be useful in ship building, for masts, spars, ship plank, &c. &c. which would probably seek a market at New-York by this channel. Iron ore also is said to exist in the vicinity of Olean, in considerable quantities. Coal mines are worked in Pennsylvania, 40 miles from Olean. The coal procured there is bituminous, and of good quality. It is now used at Olean, in the northern part of Allegany county, and elsewhere, at the furnaces.

The revenue, therefore, which may be derived from the canal, would be as follows:

19,500,000 feet of sawed lumber,	10920 00
159,000 feet sq. timber, masts, &c.	1575 00
3,800 M. shingles,	532 00
750 tons hoop-poles, laths, staves, heading, &c.	180 00
15,000 tons wheat, (500,000 bushels,)	4725 00
8,800 tons ashes, beef, pork, glass, beer, domestic spirits, butter, cheese, flour, wool, and other agricultural productions,	4752 00
6,000 tons merchandize,	5400 00
4,600 tons salt,	1269 60
4,120 tons gypsum,	1030 00
900 tons brick, clay, lime, sand, iron ore, &c.	225 00
On boats, passengers, coal, and miscellaneous articles,	6000 00
2,000 tons additional salt, in consequence of the facilities afforded by the canal and for the Allegany valley,	1610 00
1,500 tons additional gypsum, as above,	675 00
1,200 tons additional hoop-poles, staves, heading, lath, &c. as above,	1584 00
800 tons, additional merchandize, as above,	4752 00
12,000,000 feet sawed lumber, (on Erie canal,)	25920 00
150,000 feet square timber, masts, &c. (on Erie canal,)	6075 00
2,000 M. shingles,	1080 00

Total, \$78904 60

(Of this amount would be collected on the Rochester and Olean canal, \$39125 60.)

The Cayuga and Seneca canal is 22 miles long, and for the past six years the tolls averaged \$13,791.64 per annum, equal to \$626.89 per mile. The Chemung canal is 40 miles long, and produced last year, (1834,) \$8,378.05, equal to \$84.45 per mile. The Seneca lake is 40 miles in length, separates these two canals, and taking them and the lake in connection, and supposing them to form one continuous line of canal, (102 miles,) upon which toll is charged, it would bear some comparison to the contemplated Rochester and Olean canal, and by averaging the above amounts, we have \$355.67 toll per mile, for the whole distance, including the lake, equal for 102 miles to \$36,278.34. Allowing the same rate of toll per mile to the Rochester and Olean canal, the amount would be \$43,391 74.

For the fall of 1833 and the year 1834,

\* A portion of this is estimated as flour.

the tolls of the Crooked lake canal amount to \$1,674.24. Some of the property on which this toll was collected would not have found its way to the Seneca lake had not this canal been constructed. Hence, the amount thus added, should be deducted from the tolls allowed to the Cayuga and Seneca canal, which would approximate more nearly to the estimated revenue for the Rochester and Olean canal.

From a statement furnished by the collector at Geneva, it appears that in 1834 7,573,566 feet of sawed lumber cleared from his office, and from a statement furnished by Mr. Newell, that 9,374,564 feet cleared from the Chemung canal during the same season; the collector at Geneva states that about one third of this latter was included in his account; consequently, by deducting that amount, and supposing that the remainder passed through the Cayuga and Seneca and Erie canals, we should have a total amount of 13,823,275 feet.

The number of cubic feet of timber passing the same office, upon the same supposition would be 427,492 feet.

From the above statement it may be seen that the cubic feet of timber obtained from this district, bears a much greater proportion to the sawed lumber than that estimated for the Rochester and Olean Canal; which difference was made under the belief that their superior hydraulic privileges, and their distance from market, will induce them to send a greater proportion of sawed stuff.

Supposing that the canal could be constructed for . . . \$1,990,614.12

The interest at 4½ per cent. per annum, would be . . . 85,077 53

Ordinary expenses for repairs of the whole distance, 122½ miles, estimated at \$230 per mile, including lock tenders, . . . 26,895 00

Renewal in course of 10 years:

Wood work, &c. of 42 road bridges, at \$225, \$9,618.00; do. of 211 road and farm bridges, at \$139, \$29,329; do. of 4 aqueducts, \$8,164.44; do. of 44 waste-weirs, at \$105, \$4,620; total, \$51,731.44—equal per annum to . . . 5,173 14

Superintendents and collectors of tolls, and 5 tenders of reservoirs, . . . 6,800 00

\$135,905 77

Exceeding the estimated amt of tolls, exclusive of the products from, and the merchandise to the Ohio valley, by . . . \$57,001 17

Statement of the Cost of Repairs on the following State Canals, together with Superintendence and Lock Tending.

Erie and Champlain canals, from January 1st, 1828, to September 30, 1834, 9 years, per annum per mile, . . . \$608 28

Oswego canal, from 1828 to 1834, 7 years, per annum per mile, . . . 297 51

Cayuga and Seneca canal, from 1829 to 1834, 6 years, per annum per mile, . . . 301 08

If we take the Cayuga and Seneca canal for the purpose of comparison, it will be necessary to add thereto the extra number of lock tenders consequent on the greater amount of lockage on the Rochester and Olean canal in proportion to the distance, equal to \$35.41 per annum per mile, which added to the above annual cost of the Cayuga and Seneca canal, is equal to \$336.49.

Supposing that the canal could be constructed for . . . \$1,990,614.12

The interest at 4½ per cent. would be . . . 85,077 53

Ordinary expenses for the repair of the work, including extra lock tenders, at \$336.49, . . . 41,135 90

Collectors, including office expenses, salaries, clerk hire, &c. and 5 reservoir tenders, at \$160 each, . . . 4,800 00

\$131,013 53

The average cost of repairs on the canals above mentioned, is \$409.29, and adopting this as the cost upon the Rochester and Olean canal + the extra lock tenders, as before stated, equal in all to \$437.70 per annum per mile, we have—

Interest on cost as above, . . . \$95,077 53

Ordinary expenses at \$437.70 per mile, . . . 53,508 82

Collectors, as above . . . 4,900 00

\$143,586 45

Estimating the repairs on the Rochester and Olean canal to be the same as the average upon the Erie and Champlain canal, (equal per annum per mile to \$608.28,) in proportion to the cost, they would amount to \$395, including lock tenders and superintendents, which, for 122½ miles, would amount to . . . \$48,288 75

Add to this collectors' fees, including office expenses, clerk hire, &c. . . 4,000 00

Interest on cost . . . \$85,077 53

Total cost per annum, . . . \$137,366 38

Should the merchandize from the city of New-York to the valley of the Ohio river take this route, we may estimate the amount at not less than 25 millions of pounds, the toll to \$24,400, make the canal for the construction, an account of the it from which this can only be said mate, though I think it would not true amount wh

The receipts in the last year on 94 lockages per season of navigation.

Assuming the number of boats which may pass upon the Rochester and Olean canal to be one-eighth of the number upon the Erie canal, that is, about six boats daily each way, at the same ratio, the amount of tolls will be \$42,250, which approximates very nearly to the first estimate of the amount that would be collected on said canal.

A comparison may be drawn between the section of country which would probably be affected by the Rochester and Olean canal, and other sections where the amount actually furnished by and supplied to a certain number of inhabitants, may be ascertained with some degree of accuracy. This is the case with the district of country within the State of New-York bordering upon Lake Champlain; it is also well timbered, and, though the soil is inferior, in some respects resembles the southern part of the country through which the Rochester and Olean canal passes, which circumstances have led to its selection for the purpose of comparison.

From the statement marked G, appended to the report of the Commissioners, dated

January 25, 1832, it appears that the following amount of property passed Whitehall to and from the portion of New-York alluded to, during the year 1831.

Cleared south at Whitehall.

Ashes, barrels,	408
Beef and pork, barrels,	388
Coal, bushels,	3,086
C	3,258
I gallons,	33,130
C lbs.,	2,818
C	135,551
F	5,522
I lbs.,	196,722
I	1,242,640
I	3,812,392
I	583,452
Iron castings,	14,928
Leached ashes,	540,260
Merchandize,	428,600
Pig iron,	82,548
Rags,	24,298
Stone,	341,137
Sand,	152,160
Staves and heading,	248,460
Sundries,	57,726
Wool,	86,522

Cleared north from Whitehall.

Ashes, barrels,	0
Beer,	98
Beef and pork,	1,175
Flour,	6,158
Western salt, bushels,	47,084
Foreign salt,	1,342
Agriculture, &c.,	250,065
Brick, clay, lime and sand,	194,345
Buffalo robes and deer skins,	1,978
C pounds,	262,388

The above articles were forwarded to and by the inhabitants of Whitehall, Hampton, half of Fort Ann, half of Granville, Dresden, and Putnam, in Washington county, . . . 8,320

Bolton, Hague, Warrensburgh, Chester, and Johnsburg, in Warren county,	5,747
Essex county,	12,287
Clinton county,	19,344
Franklin county,	11,922

Total, . . . 64,510

From the towns of Caledonia, Avon, York, Genesee, Leicester, Mount Morris, Groveland, Conesus, Sparta, Springwater, and a portion of Livonia, in Livingston county, . . . 24,790

From China, Weathersfield, Gainsville, Castile, Perry, Warsaw, Orangeville, Middleburgh, Covington, and Leroy, in Genesee county, by . . . 23,594

From the county of Allegany, by . . . 26,276

From Danville, three-fourths of Howard, three-fourths of Conchocton and Hornellsville, in Steuben county, by . . . 8,847

From Freedom, Yorkshire, Ashford, Farmersville, Machias, Ellicottville, Little Valley, Randolph, Napoli, Great Valley, Franklinville, Lyndon, Hinsdale and Olean, in Cattaraugus county, by	12,302
From Carroll, Ellington, Gerry, and Busti, in Chautauque county, by	5,084
	98,893

Pro-rata increase since last census, deduced from the increase of the five preceding years; . . . 30,476

Total, . . . 129,371

Being a fraction more than double the number supplied by means of the Champlain canal.

The whole length of the main canal, Dansville side cut and navigable feeders is 122½ miles, and in the following statement it is assumed that each article passes an average distance of 60 miles upon the canal, the number of inhabitants supplied, and the quantity furnished by and to them being deduced from the foregoing statements:

Property going north,			
Ashes, barrels,	812	\$87	69
Beef and pork, "	776	59	86
Charcoal, bushels,	6,192	33	44

			\$10,756 99
			4,205 60

Total, . . . \$14,942 59.

The district of country included in this

comparison, does not comprise any part of Pennsylvania; but it is highly probable that the inhabitants of that section of the State in the vicinity of the work, will draw their supplies from it; and as the whole of this region is far superior in the quality of the soil to that upon Lake Champlain, it affords a fair presumption that the estimate for agricultural products and supplies to the inhabitants near the Rochester and Olean canal is not overrated. As the quantity of lumber which might be expected to pass through the canal would not be dependent upon the number of inhabitants in the district, I have not included that article in the foregoing table. Indeed, it is difficult to ascertain with any degree of accuracy, when so many circumstances are to be taken into account, to what extent this branch of trade may be carried. Although the timber is equal in quality and more abundant than in the neighborhood of the Champlain canal, yet the increased distance from market, and the consequent expense of transportation, together with the competition created by a rival market upon the Allegany river, will probably reduce the amount below that which passed through the Champlain canal in 1831.

As before mentioned, lumber is transported on the Oswego and Erie canals from Fulton, to market at Albany, 195 miles, for \$4 50 per M. As the probable distance which the lumber of this district must traverse, is about double that of the former, the price of transportation may be set down at \$9.

The timber upon Lake Champlain, which averages a distance of 129 miles from market, at the same rate, costs \$2 97½; but the expense of a trans-shipment at Whitehall, together with the delays and dangers of lake navigation, place the advantages of this region more nearly upon a par with those of the Oswego district.

Upon a comparison of the expense of transportation from all these different points, it is evident, that should an avenue to market for the timber upon the Allegany river and around the southern extremity of the Rochester and Olean canal be opened, only that portion of the timber rated as 1st and 2d, about one-fifth of the whole quantity annually manufactured, (19,500,000 feet,) would be able to withstand the powerful competition of other districts more advantageously located. Assuming one-half the amount which passed upon the Champlain canal as the quantity which would pass the Rochester and Olean canal, and supposing it to average 75 miles in distance thereon, we should have the following results, viz:

24,504,225 ft. b. m. sa'd lumber,	\$14,702 53
155,294 cubic ft. timber,	1,747 05
1,614 M. shingles,	242 10
1,438 cords wood,	1,782 00

\$18,473 68

There passed Utica, from all the lumber region west of that place, the following amount of square timber, maats, spars, &c., during the years 1830-31-32 and 33, viz:

In 1830,	262,453 cubic feet.
1831,	691,225 "
1832,	851,022 "
1833,	1,783,255 "

Averaging per year, 896,989 cubic feet.

This timber was principally brought from the vicinity of the Oswego canal, the Cayuga and Seneca lakes, and the Erie canal between Utica and Buffalo; and during the last two years, a portion was brought through the Chemung and Crooked lake

canals, making a total distance by lakes and canals, of 457 miles, averaging about 227 miles from market. The timber upon the Rochester and Olean canal will average about 345 miles from the same market. The quantity forwarded must depend upon the expense of transportation and the quality, which latter circumstance is much in its favor. If the distance from market were equal in both cases, the lumber proportionate to the length of this canal would be 351,621 cubic feet.

I find from a statement furnished by the collector at Geneva, that the property sent from that place through the Cayuga and Seneca canal, and supposed by the Commissioners to be furnished by 47,510 persons inhabiting the district adjacent to the Seneca lake, "comprising part of Ontario, Seneca, Tompkins, Tioga, Steuben, and the entire county of Yates," in the year 1829, is as follows, viz:

Of wheat, coarse grain, flour, pork, whiskey, ashes, butter, lard, peaches, apples, wool, beans, glass, furniture, sundries, hoop-poles, &c. &c., tons,	9,164
Lumber, feet,	1,232,536
Shingles, M.,	6,881

There was received during the same year, and for the same and some additional territory,

Of merchandize, tons,	2,490½
Furniture, "	104
Non-enumerated articles, tons,	205
Salt, tons,	1,203
Gypsum, tons,	1,097½

Total, . . . 5,100

Allowing the population which will be accommodated by the construction of the Rochester and Olean canal, and the Dansville side cut, to furnish to those canals as much business according to their numbers, as those included in the preceding statements, we have the following, viz:

	tons.	olls.
Of wheat, grain, &c.	24,900	\$13,445
For the supply of the same—		
Merchandise,	7,300	7,884
Furniture,	300	180
Non-enumerated,	600	648
Salt,	3,500	966
Gypsum,	3,100	930

\$24,054

The route of the Rochester and Olean canal is about equally divided into two sections, the one resembling the country bordering the Cayuga and Seneca lakes, in the richness and fertility of its soil, the other being more nearly allied to the district bordering Lake Champlain in the quantity and quality of its timber; and in making comparisons between these different sections, it will be seen that the amount of agricultural productions estimated to pass through the canal, falls short of the proportionate amount shown to have passed upon the Cayuga and Seneca canals, and that the amount of lumber calculated upon is much less than that furnished through the Champlain canal, in proportion to the number of inhabitants and the extent of timber region.

In addition it may be well to state, that in 1825, of the 3,492,000 acres lying in Cattaraugus, Allegany, Genesee, Livingston, and Steuben counties, only 476,324 were under cultivation. Although the improvements in the counties of Allegany and Cattaraugus since that period have undoubtedly been great, yet they cannot be compared in extent with those of the more northern counties, where the facilities afforded by

their proximity to the Erie canal, and also by their being able to make use of the Genesee river as a highway, have caused improvements to proceed with great rapidity, and it is beyond doubt, that should similar facilities be extended to the more southern counties for the transportation of the products of their industry, improvements would advance in that section with a pace proportioned to the fertility of the soil, and its adaptation to agricultural purposes. The benefit of these improvements will in part be reaped by the State, in the increased amount of taxable property.

Respectfully submitted.

FRED'K C. MILLS,  
Civil Engineer.

Utica, Feb. 17, 1835.

[From the Journal of the Franklin Institute.]

*Report on Mr. M. W. Baldwin's Locomotive Engines.*

The Committee on Science and the Arts, constituted by the Franklin Institute of the State of Pennsylvania for the promotion of the Mechanic Arts, to whom was referred for examination certain improvements in Locomotive Engines, made by Mr. Matthias W. Baldwin, of the City of Philadelphia, REPORT:

That they have examined several of these engines, which are now being built in Mr. Baldwin's workshop, and find in them numerous improvements, affecting nearly every part of the machine. The first they will notice are in the position and construction of the force pumps, which supply water to the boiler; the guides of the piston rods are made hollow, and the cavities are used for the chambers of the force pumps, thus giving additional strength to the guides, without much increasing their weight, and dispensing entirely with the frame and fixtures of the ordinary force pumps. Each of these pumps is furnished with five valves, three of which are situated between the boiler and the piston, and two between the piston and water tank. The valve nearest the boiler is loosely swivelled to a stem, passing through a steam-tight collar in the top of the valve box, by means of which the valve can be sounded, and, in most cases, freed from obstructions.

The other four valves are contained in one box; this box is secured to the pump by a stirrup, which can be removed by loosening a single screw, so that the valves can be taken out, cleansed, and replaced, in a few minutes. By thus increasing the facility of examining and cleansing the valves, and thereby diminishing the liability of the force pumps to obstruction, the supply of water to the boiler will be rendered much more regular and certain; and the chief causes of those fearful explosions incident to steam engine boilers will be in a great measure removed, as it is confidently believed that these accidents are generally the result of a deficiency in the supply of water.

Another improvement consists in the manner of reversing the motion of the steam valves. This is done in the English engines by means of a treadle, and a series of levers, which move the eccentrics laterally on the propelling axle, after the hooks of the eccentric rods are thrown out of gear with the rock-shafts. In Mr. Baldwin's engines, the arms of the rock-shafts extend on opposite sides of the fulcrum, and each eccentric rod is furnished with two hooks, turned in opposite directions, so that it may be geared to either arm of its rock-shaft; the eccentrics are fixed immovable upon the axle, and the eccentric rods, instead of being carried (as they usually are) to the

front of the engine, are brought to the stage at the hinder part, and there geared to either arm of the rock-shafts, at the option of the engineer. When the hooks of the eccentric rods are geared to the same arms of the rock-shafts as the valve rods are, the motion of the valves corresponds to that of the eccentrics; if they be geared to the opposite arms, the motion of the valves will be reversed; and if they be not geared to either arm, the rock-shafts and steam valves can be worked by the hand levers. The advantages of this arrangement are several; the eccentrics being firmly secured to the axle, are less liable to get loose, and out of repair; it dispenses entirely with the treadle, and its appendages, and also with four rock-shafts, and the complicated hand-gear of the English method.

But the most important benefit is, that the rock-shafts and eccentric hooks are placed immediately under the eye, and within the reach, of the engineer, which is not the case in the ordinary arrangement.

The axle of the driving wheels has also been made the subject of improvement by Mr. Baldwin. Instead of fixing the ends of the axle into the centres of the wheels, as is usually done, he dispenses with one of the arms in each crank, and fixes the wheel upon the wrist of the crank, with its centre adjusted to the centre of the axle. By this change in the form of the axle, the power of the engine is applied directly to the wheel, without the intervention of an arm of the crank, thus diminishing the strain upon the axle, and, consequently, lessening its liability to be broken. By this means, also, Mr. Baldwin has, in some measure, obviated the tendency of the driving wheels to twist upon the axles, and become loose; a very general and troublesome defect of locomotives. Another good effect, resulting from this change, is that the distance between the two cranks is increased about ten inches, which will admit of a corresponding enlargement of the boiler, and of a more advantageous disposition of the weight of the fireplace, by bringing it about fourteen inches nearer the axle. In these engines, the steam pipe is introduced into the boiler through the opening by which it usually communicates between the dome and the cylinders; and the end of the pipe beneath the dome is supported on a horse, fixed within the boiler, so as to admit of its longitudinal expansion and contraction by changes of temperature; and to avoid inconvenience from the same cause, the stop of the throttle valve is fixed on the steam pipe, instead of the head of the boiler. A twofold benefit is derived from this plan of introducing the steam pipe: first, the pipe may be made without a joint within the boiler; and secondly, a man hole in the boiler may be dispensed with; for the junction between the dome and boiler, as well as all the other steam joints, being accurately fitted by grinding, and formed without any cement, or packing, the dome can easily be taken off and replaced, and its aperture used for occasional access to the inside of the boiler.

In the construction of his driving wheels, Mr. Baldwin uses hubs and spokes of iron, cast in one piece; felloes of hard wood are framed into the ends of the spokes, and the whole is firmly bound together by a stout tire of wrought iron, with a flange on its inner edge; thus, by a judicious combination of iron and wood, he has united the strength and firmness of the former with the elasticity of the latter, so desirable in the tread of the wheel.

Mr. Baldwin has completed several engines, which combine all these improvements;

one of them may be seen in operation on the Philadelphia and Trenton Railroad, and four on the state road to Columbia; all of which, as well as one in use at Charleston, South Carolina, have given entire satisfaction by their performance.

The committee are informed that some of these improvements have been secured to their inventor by patents; and that he richly deserves to reap the benefit of them, will be admitted by any one who is aware of the present extensive use and increasing demand for these costly structures.

By order of the committee.

WM. HAMILTON, Actuary.

*New Method of Working Expansion Valves.*

Ovid, N. Y., March 24, 1835.

To the Editor, &c.

Sir,—In No. 8, vol. iv., of Railroad Journal, I observe a new method of working what are commonly called *expansion valves*, by machinery connected with the governor of a steam engine, which deserves credit for its ingenuity, but which appears to me to be quite too complicated to be of any practical utility. On examining the specification of the above, it occurred to me that an expansion valve might be so contrived as to be self-acting; and in carrying out this idea, I concluded that something like the following would operate well, viz.: Let the valve be pretty large, and of the kind called puppet valves—to the spindle of this valve a spring is attached, having a constant tendency to open the valve, which, when open, should be but a little distance from its seat—one or two small holes should be drilled through the valve, or its plate, so as to cause a trifling leakage of steam, and the apparatus is complete. The operation would be as follows: when the engine is standing still, the leakage would cause the steam to press equally on each side of the valve, and the spring would draw it open—when the piston moves, the steam would become somewhat expanded in the cylinder, at about half the length of the stroke—the valve would then be closed by the superior pressure of the steam upon its upper side, and remain closed during the remainder of the stroke—at the end of the stroke there would be a short interval, during which both feeding valves are closed against the steam from the boiler—during this time the leakage would fill the valve-box, and again produce an equilibrium of pressure upon each side of the valve, when it would again open, and again be closed as before. Such a valve would also operate in some measure as a governor.

*Remarks on the Protection of Copper Sheathing upon Ships' Bottoms.* By G. G. BONFAS.

It is a well known fact, that when dissimilar metals are placed in contact in a saline, or acid, solution, such as sea-water, they have an electric action upon each other, becoming on the one part positively, and on the other negatively, electrified; the effect of which is destructive of the positive metal. This has been too little regarded in the sheathing of vessels.

The various metals and alloys employed in the building and sheathing of a ship almost always stand in this electric relation of positive and negative to each other; and if, as is generally the case, the copper sheathing is the positive metal, it will be destroyed with a rapidity proportionate to the degree in which the electric action is excited.

The sheathing nails in common use are prepared of metals in very various proportions, regard being chiefly had to their color and tenacity; and an examination of several specimens has proved them to be as various in their electric relations with copper, as in their composition. They are generally negative to the copper, and consequently promote its corrosion. Numerous experiments have proved that the galvanic action, induced by the contact of such metals, is necessarily destructive of the positive metal; and they satisfactorily explain the irregular duration, and frequently rapid destruction, of the copper sheathing, which is often erroneously ascribed solely to impurity in the copper. If the sheathing of vessels returned from a voyage be examined, the hollows made by the heads of the nails will generally be found filled with crystals of the salts of copper, and the copper itself is often completely corroded through. In an experiment, where copper obtained from H. M.'s dock-yard was employed, and to avoid all error, each sheet was divided in half, one half being nailed to a board with pure copper nails, and the other with different samples of the nails in actual use at different dock-yards; after ten weeks' immersion in the sea at Portsmouth harbor, one half-sheet had lost two hundred and ninety-three grains more than its fellow, a second had lost thirty-two grains more than its fellow, and a third had lost twenty grains more than its fellow half-sheet: but one with nails prepared on the principles recommended in this paper, had lost thirty-four grains less than its fellow half-sheet. It is fair to presume that, if sheathing nails similar to the samples had been used with the same copper on a ship, the duration

of the sheathing would have been in somewhat the same proportion.

Copper possesses great advantages over the various alloys introduced for sheathing, from its flexibility and toughness, by which it can be applied with facility, and yields to the strain of the vessel, while, by the slow solution of its surface, it very considerably diminishes the foulness from attachment of marine vegetables and animals. The chief objections to it are, its expense—the liability to corrosion, and consequent irregularity and uncertainty of its duration—and its being too soft to be used for nails, without an admixture of such other metals as generally render them negative to, and destructive of, the copper. But it is equally an objection to the other metals and alloys, that they cannot at the same time be sufficiently soft for sheathing, and yet hard enough to drive as nails. These disadvantages may, however, be almost entirely obviated by the plan now proposed.

First, by the use of sheathing nails that shall be compounded of such metals, in such proportions, as are known not to exercise any destructive agency on the sheathing, but, on the contrary, have a tendency to preserve it.

Secondly, by attaching to the sheathing a metal positive to it, which, while itself in the process of being destroyed, shall preserve the sheathing from corrosion. For it is evident that if, when several metals are placed in communication with each other, the most positive will be destroyed, and the others preserved, the application to the sheathing of a more positive metal, or compound, will thus be a protection to it. It is also obvious that the positive metal may easily be so applied, as that its destruction shall in no degree impair the strength of the vessel, or render necessary any general or expensive repairs.

Upon this principle, (the correctness of which he fully established,) Sir Humphry Davy applied masses of zinc, or of iron, of different proportionate surfaces, to the copper to be protected. The result was, that a very strong electric action was excited, and the corrosion and waste of the copper almost entirely prevented. But he found the electric energy so intense, if the protecting metal was in a large proportion, that the copper, by the decomposition of the sea-water, very speedily became covered with an earthy accretion, to which animals and plants adhered; and the sheathing became so foul as materially to impede the ship's progress. On the other hand, if a small proportion of the protecting metal were employed, it was destroyed so rapidly, that the duration of the protection was too short to be of any value. These difficulties induced him to abandon his experiments.

The difficulties which frustrated the attempts of that eminent philosopher have been completely removed by the employment of a compound metal, which differs much less from the copper, in its electric relation, than either iron or zinc. By the use of such a compound, in which the proportions of metals may be varied as

required, a larger protecting mass may be employed, a more diffused and uniform electric action produced over the whole surface of the sheathing, and just that protection afforded which shall preserve it from corrosion, without causing foulness.

The protecting metal should be attached upon the sheathing in a longitudinal belt, or band, a few inches wide, according to the size of the vessel, from stem to stern, about the light water line; and in large vessels, an additional band should be attached to the keel. Being in the direction of the passage of the vessel through the water, it will not impede her sailing; if destroyed, it will not injure the ship; and, when necessary, it can be easily removed, and renewed, without disturbing the sheathing.

After repeated and most satisfactory experiments at Portsmouth, under the inspection of the officers of H. M.'s dock-yard, the Lords Commissioners of the Admiralty were pleased to direct that the sheathing of H. M.'s schooner Fair Rosamond should be protected on this plan, preparatory to her sailing for the coast of Africa, where she is now stationed. She was commissioned in May, 1833, and sailed first to Oporto, and afterwards to Africa. No official report has yet been received; but in November, 1833, her copper is stated, on undoubted authority, to have been clean and bright; and by subsequent accounts, it is proved to have continued so, up to the end of March, 1834.

On the whole, it has been proved that, by the adoption of the sheathing nails and protectors, the duration of the copper will be very much extended, and rendered comparatively certain; that each instance of its rapid destruction, as now so frequently occur, will be entirely prevented; and that, so far from the protectors being the cause of foulness, the sheathing will be preserved much more clean and bright than under ordinary circumstances.

Iron, and other metals, or alloys, exposed to sea-water, or acids, whether as iron cables, sheathing, or any other form, may be preserved from rust, or corrosion, on the same principle.—[London Journal.]

AGRICULTURE, &c.

*Cultivation of the Grape Vine.* By S. NEX. To the Editor of the Quarterly Journal of Agriculture, &c.:

SIR,—Believing the cultivation of the Grape Vine is, at no very distant day, to occupy an important place in American Husbandry, it gives me pleasure to observe some of your correspondents offering their remarks and opinions on the subject. In its present infant state in this country, information is much wanted, and must be very acceptable; it is therefore desirable that those engaged in this interesting pursuit, should, from time to time, mutually communicate their experiences. This can be done in no way more conveniently than through your Magazine.

With this view I send you some account of the fate of an experiment made here.

In 1823, a few vines from Long Island were planted in the garden here, and increased by additions from Long Island, New-York, and Albany, in each of the five or six following years. Above sixty plants, under nearly as many different names, were planted, from which twelve varieties were obtained, viz.: five white, five black or violet, and two grey; nine of the kinds ripened their fruit in September, and three never ripened properly. All the above were foreign vines. In 1825, one plant of the Isabella was obtained, which was afterwards increased by cutting. The vines generally came into bearing in the third year from planting; and for two or three years after afforded a considerable supply of fine table grapes. Their success induced me to undertake the establishment of a small vineyard, with the view of obtaining a pure wholesome wine for family use, as from the facts ascertained and made public, regarding foreign wines, the chance of obtaining a pure, unadulterated, and wholesome wine, from abroad, appeared more than doubtful. Accordingly twelve hundred plants, and about half an acre of ground, were prepared for this purpose in 1828, and ready to plant out in 1830. Of these, 1000 were foreign vines, and 200 Isabellas. The mildew, however, had taken place here in 1828 and '29, with very injurious effects, so as to create suspicions as to the propriety of using the foreign vine. These doubts were confirmed by the perusal of Maj. Adlam's Memoir, published about that time, and by ocular proof of their general failure in Pennsylvania and other places. The plants of foreign vines were therefore all thrown away, and only the 200 Isabellas planted, to which nearly 200 more were added the following season. Since that time, and especially during the last four unfavorable seasons, the foreign vines have not been worth their places in the garden. I have therefore only reserved a few of the younger and more healthy plants for future experiment.

The soil and situation of this farm, being mostly a strong clay and low lying, is far from favorable to the vine; the only spots any way favorable and convenient, being some slaty ridges of poor quality. One of these, nearly opposite the front of the house, was selected for the experiment, unfortunately having a public road running between it and the house. In 1832 the vines began to bear, and the error of presenting so tempting an object to public view was now made evident, the fruit being all stolen. In 1833 the plants bore so abundantly that several barrels of wine might have been made; but this trouble was saved—no sooner did the grapes begin to change color, than the sovereign people seemed to consider them as common property. Teamsters, and others of more fashionable aspect, would stop, and without ceremony go over the fence and hedge, and help themselves, sometimes observing, when interrupted, that it was very shabby to scruple so tri-

fling a freedom. In this way the bushes were completely stripped before they were half ripe. Anticipating that trespasses might occasionally occur, a hedge of honey locust had been planted along two sides of it, having in view to complete it round when the success of the experiment should be ascertained, and the extent determined on. The rapid progress, and already formidable appearance of this hedge, gives me a most favorable opinion of it; and under all the circumstances, I have judged it more advisable to abandon the present spot altogether, and begin a new plantation in a less exposed situation. This was done last spring, 1834. Thus four years are lost, and all the plants, trouble and expense, by the simple circumstance of an injudicious choice of situation.

The robbing of vineyards is a grievance not likely to be of a temporary nature. In those districts of Pennsylvania where vineyards have been successfully established, it is found, as I have been lately informed, indispensably necessary to have men to watch them night and day, from the time the fruit begins to change color until the last of it is gathered, a period of about two months. This forms a very serious obstacle to the cultivation of the vine, especially on a small scale, such as farmers or others might be induced to undertake for their own family use, the trouble and expense being too great.

A hedge of locust would certainly be a very great aid. From the experience of the small piece here which has as yet received no clipping or training whatever, I feel quite confident that a hedge of this kind, with only a little attention of training, would, in six or seven years, present a fence very difficult to go over or through. I can therefore confidently recommend the planting of a hedge of this kind as one of the first things that ought to be done in making out a vineyard. Other precautions may be necessary, such as a vigneron's or laborer's house, placed as conveniently as possible, with a good watch dog.

The only vine used in this experiment was the Isabella, which ripens here perfectly within the month of September; and in this respect it may, perhaps, be difficult to find one more suitable to this northern situation, (Saratoga county.) The Troy grape is one of the same description. The Catawba is a beautiful grape, and equally hardy, but later in maturing its fruit, which here attains the beautiful red color that gives it so fine an appearance on a table, where it is also by some preferred to the Isabella, but does not here attain the dark purple color, and rich flavor, which it acquires in Maryland and Virginia. I have lately obtained several other native varieties, which will be in bearing in two or three years, and which it is probable I may send you some account of, if I live so long. In the mean time, I shall only further add, regarding the Isabella, Troy, and Catawba, that they bear the cold or ordinary winters here with little or no injury, but that all of them are hurt more or less by severe

winters, such as that of 1830.31, and sometimes killed down to the ground, as in that of 1831.32. My situation, however, is far from a favorable one.

I shall close this rather lengthy communication; by noticing a circumstance that appears to have some bearing on the cultivation of the grape vine. I allude to the temperance cause. I am a member of a temperance society, and have signed its pledge against ardent spirits, and no one can more highly estimate its importance, or more sincerely desire its success, than I do. The question of abstinence from wine is at present under discussion, and has many advocates in its favor; and so far as regards foreign wines, if they are in fact so far adulterated by ardent spirits and other ingredients as they are said to be, and if it is true that the wines of the shops are, for the most part, only whiskey and cider in disguise, then it is right to expose the imposition, and reprobate their use; but this is certainly no sufficient reason for denouncing the pure and wholesome juice of the native vine, and thereby discouraging its cultivation. Ardent spirit is in fact the citadel and great stronghold of intemperance. Destroy that, and the battle is won, as I believe. It appears a hopeless undertaking to persuade the whole community to content themselves with water. This is grasping too much, and may hurt the cause, as a law too severe is apt to defeat its object. It is going to an extreme which I think is not necessary to the success of the cause. As to the native vine, my opinion is in entire accordance with that of the correspondents R. T. and Dr. Dwight, of Hamilton College, stated at p. 117 and 228, vol. 7, of New-York Farmer, that the general cultivation of the native grape, and introduction of its pure and wholesome juice in place of the liquid poisons now in use, would greatly promote, and prove a most powerful auxiliary to the cause of temperance, and a blessing to the world.

I am yours, &c., SENEX.

Feb. 2, 1835.

*Manifold Virtues of the Elder Tree.*—Sir J. E. Smith has remarked that this tree is, as it were, a whole magazine of physic to rustic practitioners. It is said that if sheep that have the rot can get at the bark and young shoots of elder they will soon cure themselves. The wine made from elder berries is too well known by families in the country to need any encomiums; it is the only wine a cottager can procure, and when well made, it is a most excellent and wholesome drink, taken warm before going to bed. It causes gentle perspiration, and is a mild opiate. If a rich syrup be made from ripe elder berries, and a few bitter almonds, when added to brandy, it has all the flavor of the best cherry brandy. The white elder berries, when ripe make wine much resembling grape wine. The buds and the young tender shoots are greatly admired as pickle. The leaves of the elder tree are often put into the subterranean paths of moles, to drive those noxious little animals from the garden. If fruit trees, flowering shrubs, corn or other vegetables, be whipped with the green leaves of the elder branches, it is said insects will not attach themselves to them. An infusion of these leaves in water is good to sprinkle over rose-buds, and other flowers subject to blight, and the devastations of caterpillars.—[Leigh Hunt's London Journal.]

**SILK CULTURE.**—The following letter, written by Judge Spencer, relates to a subject of great and growing importance to the people of this country.

### CULTURE AND MANUFACTURE OF SILK.

ALBANY, APRIL 7TH, 1835.

To SAMUEL M. HOPKINS, Esq.,  
Genesee, Ontario county.

From a long acquaintance, and, as I believe, a reciprocal esteem and friendship, I have thought that I could not better employ a leisure hour, than in addressing you on a topic which I regard as of high importance to our fellow citizens. You will not suspect me of insincerity or flattery, when I assure you that I know no man, whom I believe to have more enlightened views, or a more ardent patriot than you; hence the propriety of my selecting you as a correspondent on the interesting subject which I proceed to state.

Since 1830 my attention has been drawn to the consideration of the culture of silk in this country and particularly in this State. I am perfectly satisfied that no agricultural pursuit will bear any comparison with the culture of silk, as regards profit. I should not want a better income than the clear profits of an orchard of white mulberry trees, of twenty acres, at ten years old—the clear net profits of such an estate would not fall short of from \$3000 to \$5000 annually; and this profit would go on increasing with the growth of and productiveness of the trees.

You may have seen a communication made by me to the commissioners appointed by the governor, to examine into the economy, government and discipline of the state prisons, which has been published, not however extensively, it contains some matters irrelevant to the culture of silk, and omits some things interesting to those who may embark in the enterprise. You must have observed as a statistic, that our annual import of silk amounts to the value of \$10,000,000, and will increase with our wealth and population—this amount far exceeds the value of all our bread stuffs exported—this consideration ought to excite us to the enquiry, whether such a drain from the resources of the country cannot be prevented, a new source of industry be opened, which shall in a short period supply our own wants, and enable us to become exporters of either raw silk; or silk fabrics.

I consider it as a fact demonstrated, that our soil and climate is genial to the growth of the mulberry tree, and the culture of silk. Trees of this description are already growing and flourishing in various parts of the state, and I presume that the portion of this state from Skeneateles to Lake Erie, is peculiarly adapted to the mulberry, from the fact that the most delicate fruit trees come to great perfection within that region. Since 1760 the silk worm has been reared in Windham county, Connecticut, which is about the latitude of Albany; the culture of silk has been successfully prosecuted in that county, and it has reached to a large amount. The following is an extract from the Daily Advertiser of the 15th instant: "*American Silk.*—Raw silk, we learn from the Burlington Free Press, has been produced this year in Mansfield, Conn., to the amount of over \$60,000. The county of Windham, Conn., produces five tons of silk annually, valued at \$500,000, and if reeled would be worth double that sum." If this be true, and that it is substantially true I fully believe, the question is settled that the soil and climate of this state is genial to the culture of silk—it settles also another question, that it is much the most profitable business that can be undertaken.

We have the testimony of Mr. D'Homergue, a man born at Nismes in France, and brought up from infancy to the reeling and manufacture of silk, and who came to this country on the recommendation of the late James Brown, then Minister in Paris, who asserts in his essays that he was surprised to find the American silk superior in quality and the quantity yielded by the cocoons, to any he ever saw. But, my dear sir, could you have seen specimens of American silk exhibited in this city a few days since, manufactured by Mr. Gay, all doubt would be removed. These specimens were pronounced by the many who saw them, to be equal, if not superior, to any silk which had ever been seen here.

Now, sir, what are the impediments to be overcome, in introducing the culture of silk extensively in this state? And here let me observe that there is no danger of over-doing the business; there will

always be a demand in England for all we can raise beyond supplying our own wants; where, from the humidity of the climate or other causes, the silk worm is not reared.

It is necessary to devote a small space of good and fertile ground, as a nursery in which to sow the seeds. It is computed that one ounce of seed properly sown, after the ground is thoroughly ploughed, or dug and harrowed, or raked and sown, in drills at about three feet apart, will give about five thousand young trees. They require to be kept free from weeds, and injury from cattle. At two years of age they are generally fit for placing in an orchard at the distance of from 7 to 12 feet at right angles—and here the labor of man terminates, all the subsequent culture may be conducted by women and children—they pluck the leaves, and feed and tend the worms until the cocoons are formed; so that you perceive the culture of silk detracts nothing from agriculture. The greatest embarrassment hitherto has been the extracting or reeling the silk from the cocoons. The reels of France and Italy, and indeed of all parts of the world, receive the thread which consists of the fibres of several cocoons according to the requirement of the fabric to be made, in skeins, which must be spooled before it can be twisted. Two of our countrymen, Messrs. Gay and Mosely, have invented a reel which receives the thread on spools, and thus the labor and wastage of the old process is avoided. Mr. Gay assures me that an ingenious woman can be taught in a short time to reel on his reel with great perfection. A great advantage of reeling on to spools consists in its safe any easy carriage any distance without injury. We have, therefore, surmounted the most difficult process in the whole operation.

These gentlemen have also employed the several machines in use in France and England in the manufacture, so that it will require but a comparatively small capital to establish manufactories of silk in this country.

When we consider how admirably adapted to silk are our County Poor-House establishments, how the wants of the poor may be mitigated by inducing them also to enter on the culture, by obtaining leaves of the mulberry from their rich neighbors; how the middle classes of society may improve their condition by entering on the culture of silk; I feel, I confess, a strong desire to be able to persuade people to lose no time in laying the foundation of their culture by immediately setting about it in earnest, and not to let any thing hinder them from sowing the mulberry in the manner indicated this spring.

The *morus alba* or white mulberry I am satisfied is the most proper for making the best silk; the purple mulberry, which is indigenous to some parts of our country, although it will make silk, yet it is not of as good a quality. The *morus multicaulis* or Chinese mulberry, has recently been introduced into this country, but it is apprehended that it will not withstand our vigorous winters; and as the common white mulberry will withstand them, and make excellent silk, I should not recommend the propagation of the Chinese.

I forbear saying any thing on the mode of rearing the worm. I am satisfied that it does not require the care and pains to rear it in this country which the precepts of Count Dandolo would imply. In due time instructions will be given level to every capacity. May I not count on your co-operation in this most important subject.

With sincere respect and esteem,

Yours, A. SPENCER.

**LAKE ERIE NAVIGATION.**—The Dunkirk Whig, of April 14th, says, that "the Lake as far as can be seen from this place is clear of ice, and there is now no obstruction to a free navigation from this up the Lake. The steamboat William Penn, Captain Dwight, from Cleveland, is expected at this port every hour, to start for Detroit."

We hope soon to hear a similar announcement in relation to the Lake at Buffalo. It will give new life to business in that flourishing city.

There are several Steam Boats running regularly between this and the upper ports. Passengers wishing to go west may obtain passage almost any day. These boats will continue to run regularly from this port until the ice is out at the lower end of the lake.—[Erie, Pennsylvania, Gazette.]

[From the Sacket's Harbor Courier of April 14.]

The Steamboats United States, Oswego and Wm. Avery, have commenced running—the two former between Ogdensburg and Lewiston, and the latter between Ogdensburg and Rochester.—The Oswego, Capt. Homans, made her first appearance in our Harbor on Saturday last; and the United States, Capt. Van Cleave, and the Wm. Avery, Capt. Read, came in and left on Sunday afternoon and evening. They all appear to be in excellent condition, and if we may judge from appearances, we should say that their prospects for a good summer's business, are extremely flattering.

**Improvement of the Navigation.**—It will be perceived by the following letter, from the Secretary of War, addressed to the Mayor, that our citizens may count upon an early commencement and steady prosecution of the plan for the improvement of the navigation of the Hudson river. This information will be received, we are sure, with gratification by all who are desirous to promote the interests of the city, and to facilitate the transaction of the great business operations of the State, and indeed of other and far western States, which seek through this channel a market for their surplus products.—[Albany Argus.]

WAR DEPARTMENT, APRIL 14th, 1835.

Sir,—Your letter of the 11th inst. has just been received.

Capt. Talcott was some time since directed to superintend the improvement of the Hudson River. Nor is it in the contemplation of this Department to assign to him any other duty, inconsistent with this arrangement.

I understand from Gen. Gratiot, that Capt. Talcott is awaiting the decision of this Department on the question of the mode of disbursing the funds appropriated for this object, before he commences the work. The point is a new one, and has been recently made in consequence of an act passed at the last session of Congress. A course has, however, been adopted which will probably remove the difficulty, and ensure the prosecution of the improvement without delay.

Very respectfully, your most ob't servt.

LEW. CASS.

E. CORNING, Esq. Mayor of Albany.

**Canal Navigation.**—The Erie canal from Albany to Buffalo, was filled with water on the 15th of April. A great number of boats have already cleared with heavy freights of merchandise for the west. The tolls paid at this place during the three first days amount to about seven thousand dollars.—Several boats arrived at this place on Saturday from Utica; and the packets have commenced their regular trips from Schenectady to Utica.

A letter from the superintendent of the northern section of the Champlain canal, dated at Sandy Hill on the 17th, states that the water was let into the canal on his section, on the 14th, at night, and on the 15th the levels were as full as were considered safe, "with the great quantity of frost yet remaining in the banks of the canal. There were small breaches immediately after letting in the water in the vicinity of Whitehall, between the guard gate and the head of the upper lock: If we can save the other portion, it will be more than can reasonably be expected.—Watchmen are kept constantly on the line, and will be, until the frost shall have disappeared."

A letter from the collector at Dresden, of the 14th instant, states that the water would be let into the Crooked Lake Canal on the 15th; and it is presumed that the Oswego, the Cayuga and Seneca, and Chemung canals, were all in a navigable condition on the same day.

There is some frost in the canal banks between Albany and Utica, and there has been an apprehension of breaches from this cause; but none have happened. There has been a slide into the canal, about eight miles this side of Schenectady, but not to such an extent as to prevent the passage of boats.—[Argus]

**Chesapeake and Ohio Canal.**—We have just received the following interesting information from a friend, whose official situation enables him to be well acquainted with every thing connected with the Canal.—[National Intelligencer.] "I have now the pleasure of informing you

that a number of boats, loaded with Flour, Coal &c., have reached the District from Cumberland, having passed through one hundred and eight miles of the Chesapeake and Ohio Canal. It is matter of congratulation that so much of the Canal is open for use, as it is, that the prospect is fair, for its early completion to Cumberland. A great amount of trade is now on its way down the Canal; though it has been detained for some days by one of those occurrences common to the use of a new Canal, and which I anticipated when I last addressed you—I mean a breach in the embankment. This has been repaired and the use of the Canal restored."

**Grand Junction Canal.**—We congratulate our fellow citizens upon the ascertained certainty of the immediate construction of this important work the union of the Pennsylvania and Ohio Canals, by the Mahoning Valley. The necessary charters having been obtained from the respective legislatures of the two states, the commissioners will open the books to dispose of the balance of the stock, on Monday next, agreeably to their notice in our advertising columns.

Of the importance of this work to Philadelphia and Pennsylvania, nothing need be said to those who know its location. To those of our citizens who are not conversant with the subject, we would just remark, that the great line of Pennsylvania canal terminates within about six miles of the Ohio state line, the Beaver division having been completed the last season.

From thence to the Ohio canal is 79 miles, along the valleys of the Mahoning and Cuyahoga rivers. The Pennsylvania and Ohio canals will thus form the junction of the improvements of the two states on the great western line, and will be the avenue of communication between the Atlantic and the fair fertile west. It is gratifying to add, that repeated explorations by the most distinguished engineers, have shown the route to be most eligible in every respect, and especially that there will be an abundant supply of water from the natural streams.—[U. S. Gaz.]

[From the Pittsburgh Gazette.]

COLLECTOR'S OFFICE,

*Allegheny, W. D. Pa. Canal, April 11, 1835.*

Whole amount received from 1st November, 1834, to April 4, 1835, as per last weekly statement, \$4,741 55 1-2  
Amount received in the week ending April 10, 799 43

Whole amount received to April 11, 1835, \$5,540 98 1-2

Sixty-one boats cleared from this office, having tonnage, 971,874 lbs.  
Tonnage received from the East, cleared at other offices, 2,170,150 lbs.

Total tonnage of the week, 3,142,024 lbs.  
Extras.—Wood, 21 1-4 cords; Boards, 9,251 ft; Locust Posts, 100.

**Our Railroad its progress and prospects.**—Stockholders and others interested in this important work, (and who in this community does not feel an interest in it?) will be pleased to learn, that the graduation is now finished from Harper's Ferry to Winchester—that a large proportion of the necessary timber is delivered or prepared for delivery—and that arrangements have been made for procuring the iron and locomotives without further delay. Contracts have been closed and are now in the progress of execution, for laying the rails and finishing the entire work, out and out, by the first of November next—early enough to affect the price of the growing crop. Nothing is wanting to secure this happy result but attention on the part of the stockholders to the calls of the board. The instalments must be paid, or the work must necessarily languish. The stockholders will find new encouragement to diligence and punctuality in this matter of paying up; in the fact, that the stock of the Baltimore and Ohio railroad, which, while that work was unfinished, had fallen to one-third of its nominal value, has now, that the road is done suddenly risen to par—and in the further fact, that the stock of every finished railroad in the United States is above par.—[Winchester Republican.]

The Portland Argus says:

The Hon. John Anderson, of this city, and Peter H. Green, Esq. of Bath, have been appointed by the Governor and Council, Commissioners to visit Quebec, for the purpose of conferring with the authorities there upon the advantages to be derived from a Railroad from this State to that city.

We are happy to learn that gentlemen so well qualified to estimate the probable benefits to be derived from the projected project in contemplation, are appointed to collect the necessary information relative thereto. Mr. Anderson's long and intimate acquaintance with the commercial interests of this State, and his high character for honor and integrity, will recommend him favorably to the British Government in Canada, and will give weight and influence to his suggestions. Mr. Green also is well acquainted with our local concerns; and we doubt it a selection more favorable to the accomplishment of the object in view, could have been made.

**Teams versus Steam.**—Quite an animated contest has been carried on for several weeks past between those enterprising mail coach proprietors *Stockton and Stokes*, and the *Baltimore and Ohio Railroad Co.*, in the transportation of passengers between this city and Baltimore, which has caused considerable excitement among our citizens, who watch the arrival of cars and stages with much interest. On one day the stage will arrive full of passengers, at a snapping pace, full thirty minutes before the cars—the next, they come out neck and neck—or rather neck and boiler—on the third the steamer is ahead and dashes on to the depot like a thunder cloud with a streak of lightning attached to it—or a dog with a tin-pot tied to his tail. "Hurrah Stokes!" "Hurrah Steam!" are now screamed out from many a throat, with as much fervor as ever was the battle cry of Richard Cœur d' Lion. How long this steam and team contest will last we cannot say—for one of the parties seems to delight in hot water, and the other is determined not to break down whilst a wheel is left between this and Wheeling. But little we reck if it is continued as long as the Trojan war, for it is rife with benefits to the editors on the route and enables us to receive the Eastern mail some hours sooner than formerly.

The opposition of Messrs. Stockton and Stokes was caused by what they deem an extravagant demand by the Railroad Company for carrying the mail between Frederick and Baltimore. As to the merits of the case we know nothing; but we learn that the experiment of Messrs. Stockton and Stokes has been thus far liberally patronized and bids fair to continue to be so.—[Frederick, Md., Herald.]

**Heavy Penalty.**—The Supreme Court of Massachusetts has confirmed a late decision of the Court of Common Pleas, by which a Mr. Currier recovered a verdict against the town of Lowell. The suit was brought against the town to recover damages for an injury sustained by Mr. Currier in consequence of the badness of a road which the town was bound to keep in repair. The jury returned a verdict of \$3,500, which was doubled by the Court, according to the provisions of the statute, thus giving to the plaintiff the very snug and respectable sum of seven thousand dollars. The "Select Men" of Lowell will probably see the necessity, hereafter, of keeping their highways and bridges in better order.—[Courier.]

One part of the London and Greenwich Railroad, which is now advancing towards completion, will go over three thousand arches; and it is intended to make these arches to serve the purposes of cottages, and that they shall be inhabited. This is certainly a novelty, and one of an agreeable character, that carriages full of passengers and goods will go over the tops of human habitations at great speed, with the most perfect security and convenience to all parties. To get clear of all smoke arising out of these residences of men and women, which would be a great annoyance on the Railroad, the apartments or arches will be warmed by gas stoves, which will yield light and heat without impregnating the atmosphere with any noxious impurity.—[London paper.]

**India Rubber Boat.**—We have had the pleasure of examining this ingenious production, soon after its return from a most fortunate *trouting* expedition to Martha's Vineyard. The boat was invented, says the Providence Journal, by Mr. Caleb Williams, Jr., of this city; and was manufactured at the India Rubber Factory on Eddy's Point. It is constructed very much upon the plan of Burden's steamboat, with two inflated cylinders of India rubber cloth, connected upon the top by five or six beams of light portable plank, which supports a deck of boards, which may be procured at almost any place where the boat is to be used. The whole apparatus weighs about 20 pounds. The cylinders may be both inflated in from 5 to 10 minutes, and when the air is discharged may be folded into a valise. The rest of the apparatus may be conveniently carried in the bottom of a wagon or chaise. In addition to the whole, is a seat, upon which the angler may sit and hold his dominion over the finny race. This boat will sustain at least one ton's weight, and of course by enlarging the deck, would accommodate quite a party. The elasticity of the cylinders has been proved to be a protection against their being punctured by snags and rocks. We understand the ingenious contriver has applied for a patent for his invention.

**National Importance of the Cotton Manufacture.**—

The cotton manufacture arose in this country at a critical period of our history. England had just lost her American colonies; but that loss was more than compensated by this new source of prosperity springing up at home. The genius of our mechanics repaid the errors of our statesmen. In the long and fearful struggle which followed the French revolution, this country was mainly supported by its commerce; and the largest, though the newest branch of that commerce, was furnished by the cotton manufacture. To Arkwright and Watt, England is far more indebted for her triumphs than to Nelson and Wellington. Without the means supplied by her flourishing manufactures and trade, the country could not have borne up under a conflict so prolonged and exhausting. In the article of cottons alone, the exports amounted, between 1793 and 1815, to 250,000,000. From 1816 to 1833 inclusive, the declared value of the cotton exports was 306,167,518. Within the last half century, cottons to the enormous value of 570,000,000, have been sent from this country to foreign markets. It is obvious that a trade of this magnitude must have contributed largely to sustain the revenue, to prevent the national resources from being intolerably oppressed by taxation, and therefore to uphold the power and guard the tranquillity of the state.—*Baine's History of the Cotton Manufacture.*

It is now believed that volcanic action was the instrument of the destruction of Sodom and Gomorrah. The Azores, Madeira, Canary Islands, Capede Verde, St. Helen, Tristia D'Achuna, and the Isles in the Indian Ocean—particularly Bourbon, give evidence that they were of volcanic origin. Also the large islands of Java, Sumatra, Borneo, &c., with the Philippines, are evidently a continued range of volcanoes. The islands in the West Indies are also of volcanic basis; and South America is subject to earthquakes, which always attend, and generally precede volcanoes.

**The Bull Rock Light House.**—We learn that this work has been subjected to greater damage during the late gales than ever before since its erection. The spring tides in January rose to 116 feet and drifted over the building, while in ordinary tides 19 feet is the extent of their rise. The heaviest ground swell preceded the heaviest wind two days. Some large rocks called "tossers" were thrown up from the deep by the "yeasty flood," weighing 5 1-2 tons!

During the last year there were born in Paris 29,130 children, namely—14,904 males, and 14,226 females. Of these 19,145 were legitimate; 18,685 of them being born in private houses, and 469 in hospitals or almshouses; 9,985 were illegitimate, 5,473 of whom were born in private houses, and 4,512 in hospitals. Of the natural children, 1,170 were acknowledged by their parents. The deaths amounted to 24,177; namely, 12,004 males, and 12,173 females. Of these 15,340 died in their own houses, and 4,837 in the hospitals. The number of births exceeded that of the deaths by 4,953. The marriages were 8,088. In 1833 there were 27,460 births; 25,026 deaths, and 7,938 marriages.

## NEW-YORK AMERICAN.

APRIL 16—24, 1833.

## LITERARY NOTICES.

**TEMPERANCE ALMANAC.**—PACKARD AND VAN BENTHUYSEN, Albany.—This useful publication, which has, and ought to have, a most extensive circulation, is published under the superintendence of the executive committee of the New York State Temperance Society.

It is furnished at \$12.50 per thousand, and contains facts well calculated to make men feel the importance and necessity of abstinence from strong drink.

By it we perceive that in the jails and poor houses in this state in 1833 there were confined 24,169 persons, of whom 18,312 were certified by the keepers to be intemperate in their habits, only 2,366 temperate, and 3,491 doubtful.

This is a startling fact, though a reflecting mind would have supposed no other result.

The footsteps of the drunkard, however devious elsewhere, are always steady and undeviating in the downward path to poverty, crime, and disgrace. A.

**THE LANGUAGE OF FLOWERS:** Carey, Lea & Blanchard, 1835.—This beautiful volume contains a historical account of the symbolical language of the garden, together with the meaning of flowers as at present generally accepted. Here the reader may find the reason why the *Marganthum* is the emblem of repose, the *Thyme* of activity, and the *Geranium* of stupidity. Why honey-suckle represents the bonds of love, and the broken straw the painful rupture of these bonds.

It is full of curious and interesting learning, and its typographical execution, reflects credit on the printing art in Philadelphia. A.

**THE YEMASSEE:** A Romance, in 2 vols., by the author of *Guy Rivers*.—HARPER.—This is no common book. The design of the story is bold and original, and its execution is graphic and vigorous. The writer has improved amazingly since his last effort, and though there is still room for improvement, yet this work must establish him in an enviable rank among living writers. His chief defect is a too great indulgence in those metaphysical disquisitions which were so often misplaced in the mouths of his characters in *Guy Rivers*. In the present work these are very properly put forth as the views of the author speaking in his own person, but though often ingenious, and sometimes beautifully written, they do not seem always to grow out of his subject, and they are often so unskillfully introduced as to delay the action of the story, and consequently impair the interest of its finest scenes. Mr. Simms has evidently two distinct complexions to his mind, and we should like to see him try his hand at a novel of the Godwin and Brockden Brown school, if it were only to find a new outlet for those kind of speculations which appear to us out of place in a pure Romance like the *Yemassee*. It is one thing for a writer to stamp his peculiar mind and character upon his productions, and it is another thing to send all the coin from his intellectual mint with precisely the same impress. It was well enough for our author on his first appearance, to give the public a fair taste of his different powers, but we hope that hereafter he will take different and separate works in which to display his versatility; and whether his next book "turn out a song or a sermon" an exercise of discrimination in this regard will much improve its character.

The *Yemassee* we think displays as much power, fancy, and original resource as any work

of fiction, by a native writer, that we can call to mind. The author has succeeded admirably in wakening a noble and extinct race of Indians, to life, in the deep forests of the south; and the gallant cavaliers who settled his native Carolina not less than to the plumed chieftains of a hundred years ago, are made to flit with magical reality before the mental gaze of the reader.—There is, indeed, a warm tissue of poetry, pervading the whole work—an atmosphere of fancy, which raises the ideal creatures of the author's brain, somewhat above actual life, but which makes them gain in poetic vitality, all that they may lose in truth. The writer has evidently proposed to himself that master-piece of *unmeasured* poetry, (the only perfect romance, except Fenelon's *Telemaque*, that ever was written,) *Ivanhoe*,—as his model; and we only wish that he had not introduced a single touch to remind us of the ordinary novel. His attempt has been a bold one; to say that he has been perfectly successful, would be to rank his work with those two great prose epics, as they have been called, and would provoke a comparison most unjust to a writer "yet in the gristle of his youth." But to say that his production is indicative of more than mere literary talent—that it betrays the decided possession of genius—of peculiar and creative powers, will hardly be thought sufficient commendation by those who carefully peruse the *Yemassee*.

The following quotation is a fair specimen of the material of the work, and the mode in which it is wrought up.

The day had been gratefully warm; and, promising an early summer, there was a profitable show of foliage throughout the forest. The twittering of a thousand various birds, and the occasional warble of that Puck of the American forests, the mocker—the *Cooneclatee*, or *Trick-tongue* of the *Yemassee*—together with the gleesome murmur of the zephyr and brook, gave to the scene an aspect of wooing and seductive repose, that could not fail to win the sense into a most happy unconsciousness. The old oaken grove which Beas Matthew, in compliance with the prayer of her lover, now approached, was delightfully conceived for such an occasion. All things within it seemed to breathe of love. The murmur of the brooklet, the song of the bird, the hum of the zephyr in the tree-top, had each a corresponding burden.

"He does not come—he does not come," she murmured, as she stood contemplating the thick copse spreading before her, and forming the barrier which terminated the beautiful range of oaks which constituted the grove. How beautiful was the green and garniture of that little copse of wood. The leaves were thick, and the grass around lay folded over and over in bunches, with here and there a wild flower, gleaming from its green and making of it a beautiful carpet of the richest and most various texture. A small tree rose from the centre of a clump around which a wild grape gudded luxuriantly; and, with an incoherent sense of what she saw, she lingered before the little cluster, seeming to survey that which she had no thought for at the moment.—Things grew indistinct to her wandering eye—the thought was turned inward—and the musings spirit denying the governing sense to the external agents and conductors, they failed duly to appreciate the forms that rose, and floated, and glided before them. In this way, the leaf detached made no impression upon the sight that was yet bent upon it; she saw not the bird, though it whirled, untroubled by a fear, in wanton circles around her head—and the black-snake, with the rapidity of an arrow, darted over her path without arousing a single terror in the form that otherwise would have shivered but at its appearance. And yet, though thus indistinct were all things around her to the amusing mind of the maiden, her eye was singularly impressed with

one object, peering out at intervals from the little bush beneath it. She saw or thought she saw, at moments, through the bright green of the leaves, a star-like glance, a small bright ray, subtle, sharp, beautiful—an eye of the leaf itself, darting the most searching looks into her own. Now the leaves shook and the vines waved elastically and in beautiful forms before her, but the star-like eye was there, bright and gorgeous, and still glancing up to her own. How beautiful—how strange, did it appear to the maiden. She watched it still with a 'draming sense, but with a spirit strangely attracted by its beauty—with a feeling in which awe and admiration were equally commingled. She could have bent forward to pluck the gem-like thing from the bosom of the leaf in which it seemed to grow, and from which it gleamed so brilliantly; but once, as she approached, she heard a shrill scream from the tree above her—such a scream as the mock-bird makes, when, angrily, it raises its dusky crest, and flaps its wings furiously against its tender sides. Such a scream seemed like a warning, and though yet unawakened to full consciousness, it repelled her approach. More than once, in her survey of this strange object, had she heard that shrill note, and still had it carried to her ear the same note of warning, and to her mind the same vague consciousness of an evil presence. But the star-like eye was yet upon her own—a small, bright eye, quick like that of a bird, now steady in its place and observant seemingly only of hers, now darting forward with all the clustering leaves about it, and shooting up towards her, as if wooing her to seize. At another moment, riveted to the vine which lay around it, it would whirl round and round, dazzling bright and beautifully, even as a torch, waving hurriedly by night in the hands at some playful boy—but, in all this time, the glance, was never taken from her own—there it grew, fixed—a very principle of light—and such a light—a subtle, burning, piercing, fascinating light, such as gathers in vapour above the old grave and binds us as we look—shooting, darting directly into her own, dazzling her gaze, defeating its sense of discrimination, and confusing strangely that of perception. She felt dizzy, for, as she looked, a cloud of colours, bright, gay, various colours, floated and hung like so much drapery around the single object that had so secured her attention and spell-bound her feet. Her limbs felt momentarily more and more insecure—her blood grew cold, and she seemed to feel the gradual freeze of vein by vein, throughout her person.—At that moment a rustling was heard in the branches of the tree beside her, and the bird which had repeatedly uttered a single cry, as it were of warning, above her, flew away from his station with a scream more piercing than ever. This movement had the effect, for which it really seemed intended, of bringing back to her a portion of the consciousness she seemed so totally to have been deprived of before. She strove to move from before the beautiful but terrible presence, but for a while she strove in vain. The rich, star-like glance still riveted her own, and the subtle fascination still kept her bound. The mental energies, however, with the moment of their greatest trial, now gathered suddenly to her aid; and, with a desperate effort, but with a feeling still of most annoying uncertainty and dread, she succeeded partially in the attempt, and leaning backwards against the neighbouring tree, feeble, tottering, and depending upon it for that support which her own limbs almost entirely denied her. With her movement, however, came the full development, of the powerful spell and dreadful mystery before her. As her feet receded, though but a single pace to the tree against which she now rested, the audibly articulated ring, like that of a watch when wound up with the verge broken, announced the nature of that splendid yet dangerous presence, in the form of the monstrous rattlesnake, now, but a few feet before her, lying coiled at the bottom of a beautiful shrub, with which, to her dreaming eye, many of its own glorious hues had been associated. She was conscious enough to discriminate and to perceive, but terror had denied her the strength necessary to fly from her dreadful enemy. There still the eye glared beautifully bright and piercing upon her own; and, seemingly in a spirit of sport, he

slowly unwound himself from his coil, then immediately, the next moment, again gathered himself into its muscular masses—the rattle still slightly ringing at intervals, and giving forth that paralyzing sound, which, once heard, is remembered forever. The reptile all this while appeared to be conscious of, and to sport with, while seeking to excite her terrors. Now, with its flat head, distended mouth, and curving neck, would it dart forward its long form towards her,—its fatal teeth, unfolding on either side of its jaws, seeming to threaten her with instantaneous death, while its powerful eye shot forth glances of that fatal power of fascination, malignantly bright, which, by paralyzing with a novel form of terror and of beauty, may readily account for the spell it possesses of binding the feet of the timid, and denying to fear even the privilege of flight.—Then, the next moment, recovering quickly, it would resume its folds, and with arching neck, which now glittered like a bar of brazen copper, and fixed eye, continue, calmly as it were, to contemplate the victim of its secret venom—the pendulous rattle still ringing the death note as if to prepare the conscious mind for the fate which is at hand. Its various folds were now complete—the coil forming a series of knots—the muscles, now and then, rising rigidly into a hill, now corded down by the pressure of another of its folds into a valley. These suddenly unclasp, in the general effort to strike its enemy, give it that degree of impetus which enables it to make its stroke as fatal, at the full extent of its own length, as when, suddenly invaded, its head is simply elevated and the blow given.

The glance of Bess Matthews at this moment upon her enemy, assured her that the sport of the deadly reptile was about to cease. She could not now mistake the fearful expression of its eye. She strove to scream, but her voice died away in her throat. Her lips were sealed—she sought to fly, but her limbs were palsied—she had nothing left of life but its consciousness; and in despair of escape, with a single scream, forced from her by the accumulated agony, she sunk down upon the grass before her enemy—her eyes, however, still open, and still looking upon those which he directed forever upon them. She saw him approach—now advancing, now receding—now, swelling in every part with something of anger, while his neck was arched beautifully like that of a wild horse under the curb; until, at length, tired as it were of play, like the cat with its victim, she saw the neck growing larger and becoming completely bronzed when about to strike—the huge jaws unclosing almost directly above her, the long tabulated fang, charged with venom, protruding from the cavernous mouth—and she saw no more! Insensibility came to her aid, and she lay almost lifeless under the very folds of the monster. In that moment the coope parted, and an arrow, piercing him through and through the neck, bore his head forward to the ground, alongside of the maiden, while his spiral extremities, now unfolding in his own agony, were actually, in part, resting upon her person. The arrow came from the fugitive Oconestoga, who had fortunately reached the spot, in season, on his way to the Block House. He rushed from the coope, as the snake fell, and with a stick, fearlessly approached him where he lay writhing upon the grass. Seeing him advance, the courageous reptile made an effort to regain his coil, while shaking the fearful rattle violently at every evolution which he took for that purpose; but the arrow, completely passing through his neck, opposed an unyielding obstacle to the endeavor; and finding it hopeless, and seeing the new enemy about to assault him, with something of the spirit of the white man under like circumstances, he turned recklessly round, and striking his charged fangs, so that they were riveted in the wound they made, into a susceptible part of his own body, he threw himself over upon his back with a single convulsion, and, a moment after, lay dead upon the person of the maiden.

#### SUMMARY.

**Aristocratic Literature.**—The Hon. Mrs. Norton has undertaken the editorship of *The Keepsake* for next year, and is assisted, we understand, by several of her aristocratic friends in the arduous duties of preparing this publication for the forthcoming season.

"It is probable," says Humboldt, "that the higher parts of the Kingdom of Quito, and the

neighboring Cordilleras, far from being a group of distinct slands, constitute a single swollen mass, an immense volcanic wall, stretching from south to north, the crest of which exhibits a surface of more than six hundred square leagues.—Cotopaxi, Tungura, and Pichincha, are placed on this immense vault, and are to be considered rather as the different summits of one and the same volcanic mass, than as distinct mountains.—[American Monthly.]

**Important.**—Mons. Paulin has invented a fire proof apparatus, by which firemen may descend into cellars and other places, where spirits and other inflammable substances are in conflagration; being supplied with air pumped into tubes communicating with the head and mouth. A successful experiment was made, but the fireman experienced some inconvenience from the heat during the 19 minutes he remained amidst the smoke—his pulse when he came out of the cellar beating 130 a minute, but he had successfully extinguished the fire. This seems to be the application of the diving bell principle.

**Essence of Milk.**—A preparation bearing the name of *lactoline* has just been presented to the Paris Academy of Sciences. Mingled with nine tenths of water it yields new milk of the best sort, and with the proper flavor. Lactoline is procured from pure milk, principally by evaporation without heat; and it is said that the globules, when examined by high microscopic power, are found to have undergone no change. When once formed, it remains unaltered by heat or moisture.—[Medical Gazette]

The National Intelligencer says that the citizens of Mecklenburg county, North Carolina, are making extensive arrangements for celebrating the anniversary of the Declaration of Independence which was adopted by the people of that country, in public assembly, in the town of Charlotte, on the 20th of May, 1775, more than a year prior to the declaration by Congress in July, 1776.

#### TO THE EDITOR OF THE WHIG:

The questions have been asked me whether any one might lawfully keep an Inn where no spirituous liquors were kept for sale, without a license; also whether the Commissioners of Excise can in their discretion refuse licenses to taverns selling ardent spirits. While revolving these questions in my mind and preparing an answer to them, the following opinions from very high legal authority came opportunely to hand. They will be considered, I apprehend, as settling the question in the most conclusive manner; and as the subject is one of great importance to the public, and particularly to the Commissioners of Excise, I solicit the publication of the following documents in your next paper. By so doing you will greatly subserve the cause of morality and good order, and greatly oblige

A FRIEND.

Utica, April 4.  
*Legal opinions in relation to the Right to keep a Public Inn without license, and the duty of the Boards of Excise.*

I have been desired to state my opinion in writing on two points growing out of the title of our statute regarding "Excise and the Regulation of Taverns and Groceries," 1st vol. Revised Statutes, pages 677—viz:

1st. Can a public inn be kept without license?

2d. Can the Commissioners of Excise refuse to grant any tavern license whatever, if they think that none is necessary?

After the clear opinion given by his Honor, Chief Justice Savage, on one of these points, it seems not very fitting for a member of the bar to say much in addition to it. I will, therefore, state one or two considerations only, and that briefly.

The business of an innkeeper is to keep a public house for the entertainment of travellers.—It is a public employment at common law; and by the common law, long before any statute extended on the subject, innkeepers had peculiar, well established rights, and were under peculiar liabilities.

As the business of innkeeper did not originate in any statute, so it continues by the State Constitution a part of the common right of the citizen, unless restrained by statute.

There is no provision in any part of our revised statutes, (nor was there in our late statutes,) which at all restrains the right of keeping an inn. Any citizen may set up a public inn if it be not a nuisance. He may receive travellers, charge for entertainment, give any credit he pleases, and detain property as security for his bill. On the other hand, he is under so strict a liability to his guest, that even robbery, fire or rebellion, will not excuse him for the loss of a lodger's effects. There is no prohibition, nor penalty in the law, for any act he may do in the regular way of innkeeping, though he have no license.

But without a license he cannot sell the liquors for which an excise is required by the statute.

The business of retailing spirituous liquors, if carried on in an inn, turns it into a tavern. It is this selling which is so strictly regulated by our law. And if a man has a license for a tavern, he must keep an inn also, because the statute has so ordained. But if he will keep an inn, he may do it without keeping a tavern.

The second question is in substance, whether the Commissioners are obliged to grant at least some licenses.

All the regulations in this title, are regulations of careful, anxious restriction. They all plainly refer to the retailing of spirituous liquors as a great evil which is to be restrained as far as possible. The law does not say, nor imply, that any licenses shall be granted; and it states many limitations and exceptions according to which they shall not be granted. The whole scope of the law is to restrain, regulate and diminish the business.

As one example among others no license can be granted unless absolutely necessary for the actual accommodation of travellers. It must not be granted on the ground of merely some convenience, nor for uncertain accommodation, nor for the accommodation of any at all except travellers.

The neighbors near an inn can not be travellers there, and the law does not allow a tavern for the accommodation of the neighborhood.

As by this restraining law, no license can be granted except it be absolutely necessary, nor except it be so for travellers, and for their actual accommodation,—so the Commissioners can not duly grant the license unless they are satisfied of all the points mentioned in the 6th section, and among them, that a tavern is thus necessary. If there is no place in the town where the Commissioners are satisfied that a tavern is actually, absolutely necessary for travellers, then no license can be granted by such Commissioners in the conscientious discharge of their duty. They must be so satisfied in their own minds before they can grant a license.

As petitions are often circulated to influence the Boards, it may be proper to mention that the duty of judging in these cases is cast upon the commissioners themselves, and they have no right to throw the responsibility upon any other persons whatever. If the commissioners are not satisfied that a tavern is absolutely necessary for the accommodation of travellers, they are in duty bound to refuse the license, without regard to the numbers or influence of those who may request it to be granted.

SAMUEL L. HOPKINS.

GENEVA, 19th March, 1835.

I concur in the opinion, that a public inn may lawfully be kept without license, and that the commissioners of excise may lawfully refuse to grant any tavern license whatever, if they think that none is necessary.

NAT. W. HOWELL.

I am of opinion that under the statute 1st Revised Laws 677, any person may keep a house of entertainment, without a license, provided he abstains from selling strong and spirituous liquors and wines; and that the commissioners of excise may not only lawfully refuse to grant any tavern license if they think none to be necessary; but that they exceed their powers and violate their duties if they grant licenses that are not absolutely necessary for the actual accommodation of travellers.

A. SPENCER.

We concur in the preceding opinions of Judge Spencer.

JOHN SAVAGE.

JACOB SUTHERLAND.

**Serious Disaster on the Railroad.**—The passengers by the Railroad Line from Philadelphia, did not arrive in New York, yesterday afternoon till 5 o'clock, having been detained on the road by a serious disaster, the particulars of which we have learned from one of the passengers, and are as follows:—

About six miles this side of Bordentown, the baggage car, which is always next to the locomotive, was discovered to be on fire, having caught from the sparks from the furnace. The engine was immediately stopped, and every exertion was made that the circumstances of the case would admit, to arrest the progress of the flames, but, we regret to state, that the greater part of the passengers' baggage was destroyed before the flames could be controlled. Our informant states, that when the fire was first discovered, the flames appeared to issue from the very centre of the baggage; the car was in a few seconds completely enveloped in a sheet of fire, and the wind being very high at the time, it burnt with great fury. The flames also communicated to one of the half-price cars, which was slightly damaged.

Among the passengers who were the greatest sufferers, were Mrs. R.—e, of Boston, and Mrs. Austin, of the Theatre. The former lost a large quantity of valuable clothing, worth fifteen hundred dollars, but fortunately saved her diamonds and other jewellery. Mrs. Austin also lost all her baggage, including many valuable articles of dress, but saved a box of jewels which was providentially taken from the centre of her trunk.

A German gentleman and his wife who lost all their clothing, were fortunate enough to recover a tin box, which was in one of their trunks, containing documents necessary for the recovery of a large estate in Europe, wither he is proceeding for that purpose.

Mr. Knowles, of Amherst, Mass. had a package in his trunk, containing \$15,000, which was fortunately rescued from the flames, the top of the trunk having been burnt up. We understand the money was put in his charge by one of the Philadelphia Banks, for a New York Bank.

A rough estimate of the loss was made by the passengers, and it was computed to amount to upwards of five thousand dollars.

We understand the Agent of the Company acted with great coolness and intrepidity, and did every thing in his power to arrest the progress of the flames.

When the passengers got on board the steamboat, a meeting was called to take the matter into consideration. Joseph P. Grant, Esq. of Baltimore, was appointed Chairman, and J. J. Smith, Jr. of Philadelphia, Secretary. A committee of three was appointed to call upon the Company and represent the nature of the accident, and request remuneration to the sufferers.

Since the above was in type, we learn from another passenger, that the opinion was very prevalent among them that the fire was the result of design, and that it did not originate from sparks from the chimney. He says that the baggage was covered with a thick tarpaulin, and the fire evidently proceeded from the centre of the baggage.

P. S. The mail bag, containing a few letters and papers, was also destroyed. The fragments of forty three letters were received at the New York Post Office last evening, and have been repacked to be returned to Philadelphia this day. One of them contained a check for five hundred dollars.—[Gazette.]

**Balloon Ascension.**—M. Clayton, who ascended from this place in a balloon, the evening of this day week, has not yet been heard from with any certainty. It was his intention to proceed all night, and reach if practicable some point east of the mountains. The course upon which he departed would conduct him south of Richmond, in Virginia, approaching North Carolina. If he succeeded in keeping up all night, and reaching the Atlantic border in this direction, we may not hear from him in several days. So if he was lost in the night in the wilderness country over which his course lay.—[Cincinnati Gaz.]

**Unprecedented Gain.**—Five lots of ground were bought in the Sixth Ward of the city of Brooklyn, in 1825, for twenty dollars per lot, and yesterday the same were sold by Messrs. Franklin & Jenkins, at auction, for ten thousand dollars.

**CHICAGO AMERICAN.**—We publish to-day, the prospectus of a newspaper about to be established in the thriving village (city we might almost call it) of Chicago, Illinois.

Mr. Davis, the proprietor, is a young gentleman in whom the citizens of Chicago will find all that is desirable as a man of business and character—and to their kindness and patronage, from a long and intimate acquaintance, we can most cordially recommend him.

#### PROSPECTUS OF THE CHICAGO AMERICAN.

IN proposing to establish a new paper under the above title, in this great and growing place, the subscriber, in conformity with usage, takes this mode of setting forth the reasons which thereunto move him.

First of all, he thinks there is both a want of, and room for, such a paper as he will endeavor to publish,—a paper which shall be American always, and in all things, and which, moreover, identifying itself with the interests and character of Chicago, and of the vast and fertile region of which it is the heart,—may hope to grow with the growth of this Young Giant of the Far West.

Its politics will be those which the Constitution, as expounded by the men who framed it, inculcates. With party, it will have as little to do as possible; and the little, if it must have a place, shall always be exempt from personality.

As a record of passing events, of current literature, of the march of agriculture, commerce and manufacture, and especially of the progress of internal improvements, in which Chicago has so deep an interest, it will aim always to be accurately and early informed, and thus endeavor to consult alike the tastes and the wants of the community, with which it now, for better and for worse, desire to identify itself.

With this brief explanation of the course he proposes to follow, the subscriber ventures to solicit the aid and patronage of the residents of Chicago, of Illinois generally, of Michigan, and such other districts of country, as may feel interested in a paper to be conducted on the principles here set forth.

The CHICAGO AMERICAN will be printed on a large sheet, and will be published weekly at \$2 50 per annum, if paid in advance, or \$3 at the expiration of six months.

a-16 if

THOMAS O. DAVIS.

The following paragraphs were taken from the Galena Advertiser of 21st March:—

Proposals for five new papers are already before the public. One at Jacksonville—one at Pekin—one at Quincy—one at Rushville, and one at Chicago. This is certainly an evidence of the advancing prosperity and population of Illinois.

A rich and valuable vein of Lead Ore has been lately discovered on the Merrimac River, in Franklin County, Mo., about 50 miles from St. Louis. "On one tract of land, contiguous to the Merrimac, the earth has been opened in various places for more than three quarters of a mile in length, and in every instance a large vein of rich mineral was found.

**BOUNDARY QUESTION.**—The Ohio State Journal of the 11th inst. states that "no direct intelligence from the disputed territory has been received here since the Governor left for Perryburg, prior to the 1st instant. We have no fears of any collision taking place with the Michigan authorities; and we presume the Commissioners appointed by our Legislature, to re-survey and mark the line as claimed by Ohio, will meet with no interruption in the discharge of their duties. Michigan, it appears has suspended her military preparations and movements for the present, leaving the adjustment of the immediate dispute in the hands of the President. The following paragraph contains the only additional information we have on the subject:—"

#### POSTSCRIPT.

**News from the Boundary.**—A gentleman (Col. Andrews,) who formed one of the Governor's suite, has just returned to town, from whom we learn that all danger of collision with the Michigan authorities is removed. The citizens of the disputed territory, who are unanimous in favor of being attached to Ohio, had held their township elections on the day appointed, and had organized under the laws of this State. No interruption was offered on the part of Michigan, and the Commis-

sioners were proceeding with their survey of the line. The Commissioners appointed by the President were also on the spot, having previously had a conference with the Michigan authorities.

The Detroit Journal and Advertiser of April 10th, says that

We learn that the commissioners appointed by the President to act as mediators between Michigan and Ohio, have had an interview with Governors Lucas and Mason, and that their mission has been unsuccessful—Gov. Lucas having refused to defer the survey of the Northern boundary, and declaring that he would not yield one jot or tittle, to the solicitations of the commissioners. Some difficulties having already occurred on the border. We are informed that the sheriff of Monroe and some of his deputies have been arrested in the discharge of their duties, by the authorities of Ohio, and carried to Toledo. A good deal of excitement prevails at Monroe, and a serious conflict is apprehended.

**The Season.**—The Macon (Ga.) Telegraph, of 9th inst. says—"There was a smart frost yesterday morning."

**Relics.**—Mr. William Shaw, who found the remains of a deceased British officer or soldier near where the U. S. Arsenal now stands, has given us an opportunity to examine them.—They consist, first, of two bones and a tooth, a large half round button of silver or some composition resembling it, and two smaller ones of the same shape and metal, a pinchbeck buckle about the size of a shoe buckle, but to straight for that, and probably intended for a sword belt; a small bullet, much flattened on one side, and two guineas, one of the reign of William and Mary, the other of Queen Anne.—[Pittsburgh Gazette.]

**Fine Fish and Fine Fishing.**—Harry Slade, Esq. caught with his hook and line on Saturday last, off Buffalo Harbor, a Salmon Trout weighing 27 lbs.; and on the Wednesday previous, Moses Evans, alone, with hook and line, took twenty-four, weighing 230 lbs. Next week, if old Boreas will shift his course, we propose seeing what an Editor can do, but at this moment Lapland is a fool to our Bay.—[Buffalo Journal.]

[From the Portland Advertiser.]

**THE MAR CLAIM.**—Our readers in this vicinity have lately heard considerable about the Mar Claim, and there is a Mar Stock in the market, in which it is said considerable speculations have been made. The following account of the origin and nature of this claim is given in the Lexington Recorder, and probably comes from a gentleman at that place who has paid some attention to the investigation of the subject:

**The Earl of Mar.**—This nobleman who commanded the army of the Pretender in the Scottish rebellion of 1719, is said to have left a son and a daughter at Newcastle upon Tyne, when he and the unfortunate Prince made their escape into France. Soon after, the son, quite a boy, came to America, and landed at Portsmouth, N. H., where he lived a short time and finally married in Kittery, in this county. After the British government granted a pardon to the Earl with permission for him to return to his estate at Newcastle, he sent for his son who went to England and had an interview with his father. It was agreed that the son should return to America, and accompany his wife to England, but circumstances of an extraordinary nature detained him for two or three years in this country; at last he was suddenly taken sick and died.

He left six children, who settled in different parts of Maine and New Hampshire, from whom originated nearly all in this part of America who bear the name of Mar. The heirs have lately taken measures to recover the immense property left by the Earl of Mar in England, and have sent an agent to Newcastle upon Tyne for this purpose. The property is said to amount to the enormous sum of sixty or eighty millions of dollars.

[From the Albany Evening Journal of 22d.]

**GALE ON LAKE ONTARIO.**—Extract of a letter from Sackets Harbor, dated April 12, two gentlemen in this city.

"There has been a severe gale on our Lake. The steam boat United States is up the Lake and

has been due at this port according to her advertisements, three days. The Avery, Captain D. Read, was about twenty miles up the Lake and could not get back to this port. She would not steer, and rolled broad-side in the sea until her anchors brought her up off Pillar Point, in Chaumont Bay, where she rode out the gale, and pitched so as to split her night heads and haue holes, with her chain cable. The Oswego was in the river and was here to-day. The America has not been out yet. The Great Britain is ashore, near York, and will probably be lost."

[From the Charleston Patriot.]

PENSACOLA, MARCH 28.—*Naval*.—The United States sloop of war Vandalia, arrived here from a cruise on Tuesday last. She was at Vera Cruz several days. Order is restored there. The whole of the West India Squadron is now in this harbor.

The following is a list of the officers of the United States sloop of war Falmouth, which arrived last week:

Laurance Rousseau, Master Commandant.  
Robert Ritchie, Lieutenant, "  
Wm. Pearson, "  
James H. Ward, "  
Henry K. Thatcher, "  
Charles G. Hunter, "  
Henry S. Coulter, Surgeon.  
Nathaniel Wilson, Purser.  
William Lambert, Acting Master.  
Benjamin Bunker, Acting Master's Mate.  
Albert S. Whitner, Midshipman.  
J. W. Brackett, "  
Wm. H. Carns, "  
Gough W. Grant, "  
Napoleon Collins, "  
Samuel C. Barney—Boy—Act'g Mid'n.  
Samuel Stanley, Act'g Bos'n.  
Thomas Robertson, Act'g Gunner.  
Samuel V. Hawkins, Sail Maker.  
Leroy H. Anderson, Captain's Clerk.  
Severn D. Moulton, Purser's Steward.

U. S. SHIP PEACOCK.—This fine vessel has just been fitted out at our Navy Yard, for a long voyage to the Eastern Seas, and her equipment, conducted under the superintendence of Commodore Ridgely, the able and indefatigable commandant of the station, is quite worthy the high reputation which our ships sustain abroad. She will carry E. Roberts, Esq., the diplomatic agent to whose labors we are indebted for the treaties with the Sultan of Muscat and King of Siam. He bears with him the ratification of those treaties, and goes to complete and establish those relations of amity and commerce for which his enlightened services have already laid the foundation. He will be accompanied by scientific agents, and from their joint observations during the long voyage of the ship, we may expect to derive much information regarding those comparatively unknown countries that will be valuable to commerce and to science.

The following list of the Officers of the Peacock is furnished by the Army and Navy Chronicle:—  
Commander—E. P. Kennedy, Esq. Lieutenants—C. K. Stribling, G. N. Hollins, W. Green, C. C. Turner, Murray Mason. Fleet Surgeon—W. S. W. Ruchenberger. Assistant Surgeon—David Harlan. Purser—F. G. McAuley. Acting Master—S. Gordon. Passed Midshipmen—J. Woems, W. Roger Taylor, W. Leigh, B. S. B. Darlington. Midshipmen—J. Cotree, G. W. Chapman, W. S. Drayton, C. Richardson, E. S. Hutter, P. C. Vanwyck, S. B. Lee, B. D. Izard, J. C. Williamson. Boatswain—John Knight. Gunner—Archibald Lewis. Carpenter—Wm. Peterson. Sailmaker—James Ferguson.

#### MISCELLANY.

Lord Brougham.—We learn from a private source that this eminent nobleman and lawyer has consented to act as Judge of Scots Appeals in the House of Lords. As the office brings no emolument, his Lordship is entitled to the greater praise, and is thus relieved from the mean snailions which his enemies are so ready to attach to his character. Lord Brougham has long been anxious that the judicial and political functions of the Woolpack should be separated; and in thus accommodating a successful rival, and leaving him to do justice to the Court of Chancery, offers, to our minds, a very strong proof, that heaven labor for its own sake, and, as regards his

retiring pension, is anxious to get rid of an oversensitive feeling that he is putting the country to charges for nothing.—[Dumfries Cour.]

*Law of Arrest for Debt in England.*—If the law of arrest continue in this country after the noble effort made by Sir John Campbell, (which, if he firmly and vigorously persevere to the end, will transmit his name with honor to posterity, with those of the Jenners, Howards, and other illustrious benefactors of their kind,) it would mark England for the most inhuman and debased nation in the civilized world. We have said that the only real blessings on earth are *Health and Liberty*. Let us for a moment, and, for the sake of an illustration, alter the position. Suppose, for instance—and there is as much reason for the one as for the other—suppose that, instead of taking away a debtor's freedom, the creditor should be allowed to take away his physical constitution. We should have this or that vindictive person, employing a surgeon instead of an attorney, or an apothecary in lieu of a bailiff; and he would order him to go every day to his victim, and draw off an ounce of blood, or inflict a wound of two inches, or administer the modicum of a dose of poison; so that within six months the debtor should be put out of pain. We protest that we do not think this would either be so cruel, or so contrary to the merciful dictates of Christianity, as the pangs and miseries inflicted during the long lingering years under the present system of imprisonment for debt.—[London Literary Gazette.]

The new Minister of the Finances in Prussia, the Count Alvensleben, has devoted himself with zeal to the subject of internal improvements, and particularly to the constructions of railroads. A commission has been sent to Paris, to examine the steam carriages of Messrs. Diebz and Ada, with the view of encouraging a similar experiment on the great roads of Prussia.

*Rome.*—The finances of the Episcopal States are stated to be in the most promising condition, under the administration of the Treasurer General, Mr. Tosti. The revenues of the last year were ample for defraying all the expenses, including a deficit of 700,000 crowns of the preceding year, and there is a surplus in the treasury.

A NEW STATE.—A German paper contains the information that some scattered tribes of Jews, who maintained a sort of independence for a long time, about the southern coasts of Arabia, have been lately visited by Captain Owen. He discovered that an Israelite, of the name of Mahomet Bin Akel, has founded among them a new sovereignty, and raised himself to the rank of Sultan of Morbut and Dechoffar. By means of his wealth, he has purchased a thousand Nubians, whom he has formed into an army, and with this imposing force he has conquered the whole coast from Feutar to Ganew and Hadramond.

*Cowper, Johnson and Watts.*—The following letter from Cowper to Newton was written in 1781, when the "Task," &c. was published: "I am glad to be undeceived respecting the opinion I had been erroneously led into on the subject of Johnson's criticism on Watts. Nothing can be more judicious, or more characteristic of a distinguishing taste, than his observation upon that writer; though I think him a little mistaken in his notion that divine subjects have never been poetically treated with success. A little more Christian knowledge and experience would perhaps enable him to discover excellent poetry upon spiritual themes in the aforesaid little doctor. I perfectly acquiesce in the propriety of sending Johnson a copy of my productions; and I think it would be well to send it in our joint names, accompanied with a handsome card, such a one as you will know how to fabricate, and such as may predispose him to a favorable perusal of the book, by coaxing him into a good temper; for he is a great bear with all his learning and penetration."

*Plagiarism.*—A Monsieur Lemare has brought forward before the Academy of Sciences, a stove under the classic cognomen of *aerotherme* or *air heater*, which is evidently no other than our countryman Dr. Not's most ingenious apparatus. The heated air circulates around the fire and may be directed in its course, and regulated in its temperature at pleasure. This is not the first time American genius has been robbed by foreign pretenders.

The publishers of the Journal des Debates, Constitutionnel, and several other journals of Paris, have entered a complaint before the tribunal of correctional police, against the publishers of the French Echo, and the Eclair, for habitually republishing, without acknowledgment, political and literary articles, written exclusively for the journals, whose publishers make the complaint. The cause was brought on for a hearing on the last day of February, and was postponed for a month.

The entrance of the young King of Persia into Teheran, in December last, is described as peculiarly magnificent, and marked with all the characteristic ceremonies of oriental splendor. His majesty mounted his splendid charger at the *Azar* fixed by the astrologers—the saddle was embossed with precious stones—the footmen of the court, the bands and the cavalry were in richest costume—camels, oxen, and sheep were sacrificed on the road side as he passed, and bottles, filled with liquors, and adorned with flowers, broken, as is the usage. The ambassadors of England and Russia were in the train, and artillery, and companies with congrave rockets.

*Reminiscences.*—The following items are taken from a memorandum book kept by one of our oldest citizens, who is now in the vigor of health.—[Merc. Adv.]

1788—July 23d.—Federal procession, in the city of New York, in honor of the adoption of the Constitution.

August 21st.—At 12 o'clock, the foundation stone of Trinity Church was laid, by the Rev. Samuel Provost, Bishop of the Episcopal Church of the State of New York. On the stone is the following inscription:—"To the honor of Almighty God, and the advancement of the Christian Religion, the first stone of this building was laid (on the site of the old Church destroyed by fire in 1776) on the 21st day of August, A. D. 1788, in the 13th year of the Independence of the United States of America. The Right Reverend Samuel Provost, D. D., Bishop of New York, being Rector. The Hon. James Duane, Esq., the Hon. John Jay, Esq., Church Wardens."

October 6.—Federal Hall begun, for the accommodation of Congress.

1789—April 30.—George Washington took the oath as first President of the United States.

1790—March 25.—Trinity Church consecrated.

April 17.—Died in Philadelphia, Benjamin Franklin, in the 85th year of his age.

May 21.—Corner stone of Government House laid.

1791.—Great fire in Duke street, New York—Custom House burnt.

1893—January 1.—First Anniversary of the Mechanic Society in the city of New York: Anthony Post was elected President, Daniel Hitchcock, Vice do.

January 22.—Louis 16th beheaded.

August 3.—French fleet arrived at New York. September.—Great Fever raging in Philadelphia.

September 17.—Intercourse between New York and Philadelphia stopped, on account of fever in Philadelphia.

October 14.—Mrs. Carey's house torn down by a mob.

October 16.—Queen of France beheaded.

1794—March 26.—Embargo laid in America.

May 17.—John Jay sailed on board ship Ohio, Capt. Kemp, as Envoy Extraordinary to the Court of Great Britain.

1795—May 27.—John Jay arrived from England, in ship Severn, Capt. Goodrich.

1796—December 9.—Great fire at the Coffee House.

1797—March 3.—George Washington retired from public service.

March 4.—John Adams, President of the United States.

1798—January 29.—New Theatre opened, with the pieces—"As you like it," and the "Purao."

1799—February 10.—Captain Truxton captured French Frigate L'Insurgente, of 32 guns.

December 14.—George Washington died.

1800—April 10.—Frigate President launched.

April 24.—Frigate New York launched.

### Biographical Sketch of Mohammed Ali Pacha of Egypt, Syria and Arabia.

MOHAMMED ALI PACHA was born in the year of the Hegira, 1182, corresponding in the Christian era to the year 1769. It is not unworthy of remark, that this year also, gave birth to Napoleon Buonaparte. Alike distinguished for military genius, the characters of these chieftains, are equally marked by insatiable ambition, and unreposing activity.

Early education, the advantages of science, and a more prominent field of enterprise, have given to the history of one, an éclat and brilliancy of success which are denied to the other. Yet, he who would learn to read and write, at the age of 45, as did Mohammed Ali, and from the humble culling of tobacco vander, rise to the throne of an extensive empire, can be no ordinary man, and may bear some comparison with the Hero of France.

With a disciplined army of 50,000 men, a navy of nine line of battle ships, and a revenue of twenty millions of dollars, he may be supposed to have the means of consolidating his power, of establishing his dynasty, and of maintaining his *de facto* independence. He desires to raise Egypt to the level of European civilization, surpassing that of the august age of El-Mamoun and Haroun el Rashid. The patronage which he gives to arts and science; his encouragement of Europeans of talent; his printing-presses; polytechnic, elementary, and medical schools; his factories and internal improvements, are evidence of enlightened views in civil administration.

The Pacha is commonly called Mehmet Ali, although his name is written Mohammed Ali.—Supreme veneration for the name of his Prophet, forbids a Mussulman to desecrate the name of Mohammed, by colloquial use, and therefore is this distinction made in the pronunciation of the name. He is also called Hadgi Mohammed, or pilgrim, having performed his pilgrimage to Mecca, which is one of the five great duties of the acolytes of Islam. Among the numerous amputated titles, given to him by his courtiers, that of *Hidivi*, or *divine*, is remarkable. Of the Roman Emperors, Augustus was the first whom clambering adulation apotheosized, and associated with divinity.

Mohammed Ali Pacha, was born at Cavalla, a small maritime town of Rumelia, in European Turkey. This district is renowned in the east, for its aromatic tobacco, which rivals that of Latakia, among the dreamy smokers of the oriental *chibouque*. Cavalla is distant ninety miles to the east of Salonica, the ancient Thessalonica, where there is now established a consul of the United States.

Ibrahim Agha, the father of Mohammed Ali, was the chief of police in the town of Cavalla.—At the death of his father, Mohammed Ali, being then quite young, the *Tchorbadgi*, or governor of Cavalla, took him into his service.

An opportunity early presented itself, whilst Mohammed was attached to the family of the *Tchorbadgi*, by which he acquired a character for prudence, ingenuity and bravery. A certain village, within the jurisdiction of Cavalla, had refused to pay its usual contributions. The *Tchorbadgi* was undecided as to the most efficient measures to be adopted on the occasion, and Mohammed Ali promptly offered his services; they were accepted, and a body of armed men was appointed to accompany him. He proceeded to the village, and at the hour of prayer, when announced by the Muezzin from the Minaret, he repaired to the Mosque to perform his devotions. After having recited his prayers, he sent to request four of the principal Turks of the village, to wait on him, under the pretext of important business.—These persons not suspecting any design upon them, repaired to the Mosque. Mohammed Ali immediately commanded his followers to seize and bind these chief villagers, who were conducted to Cavalla, amidst the threats and pursuit of the inhabitants.

This dashing act of bravery and finesse, resulted in the payment of their contributions by the refractory villagers; and the *Tchorbadgi* was so well-pleased with it, that he promoted the youthful Mohammed to the rank of *Belouk Basha*, or captain of a company. He also gave

him in marriage one of his relations, a widow, by whom he had three sons, Ibrahim, Toussoun, and Ismael. This marriage of a widow has given rise to the report, that Ibrahim Pacha, the conqueror of Acre and Syria, is the stepson of Mohammed Ali.

Of these three elder sons, Toussoun and Ismael Pachas, died some years ago. The former conducted a successful expedition against the Wahabees of Arabia.

A most faithful and eloquent history of this formidable sect of Islam, is to be found in the popular novel of Anastasius, by the late Thomas Hope.—Ismael Pacha was commander-in-chief of the expedition against Seunnaar and Kordofan, where he was assassinated by one of the subjugated chiefs.—A blow inflicted on this chief by the Pacha, was avenged by his assassination. It was this expedition to Seunnaar, which Mr. George Bethune English, of Boston, accompanied, in a military capacity, and an account of which he subsequently published.

Ibrahim Pacha, the remaining son, is now in Syria, with a numerous army reposing upon the laurels acquired in his late battles with the Grand Vizier, and the Sultan's disciplined troops.

Mohammed Ali, after his marriage, joined to his military profession, the trade of a merchant, and became an extensive dealer in tobacco, the richest product of Rumelia. In this trade, he acquired his first notions of commercial monopoly, to which he has since more strictly adhered than comports with sound principles of political economy, or the well being of his Egyptian subjects.

He was soon called to enter upon a wider and more important field of enterprise. Napoleon had invaded Egypt, and the battle of the pyramids had defeated the Mamalukes, opened the gates of Cairo, and secured possession of the country. In 1800, the Sublime Porte, in alliance with Great Britain, and aided by her forces, made preparations to recover Egypt; and among the contingents of troops required by the Porte, was one of three hundred men from the district of Cavalla. They were raised by the *Tchorbadgi*, and placed under the command of Ali Agha, his son, and Mohammed Ali was appointed to the double office of Ali's mentor, and his second in command. Ali Agha soon became dissatisfied with the fatigue of camp, and returned home, leaving his company under the orders of Mohammed Ali. He thus acquired the rank of *Bis Bashee*, in the army of the Grand Vizier.

After the victories of Aboukir, and the camp of Caesar, gained by the British troops, the Grand Vizier commenced offensive operations. Mohammed Ali, in frequent engagements with the French divisions, signalized himself by great personal bravery and by military tact, if not by strategic science.

The limits of this sketch require us to pass over the numerous incidents of the Pacha's eventful career, during which he was alternately applauded and reproved by his superiors, until the important period of his election, as Governor of Egypt, by a deputation of *Scheiks*, on the 14th of March, 1805. The country was at that period, a prey to intestine war, caused by those petty tyrants the Mamaluke Beys. He skillfully evaded or resisted their attacks and machinations, and succeeded in obtaining, two months after the election, his confirmation as Pacha of Egypt, by the Sublime Porte.

The policy of the British Government at that epoch favored the civil dissensions created by the Mamaluke Beys. It openly declared itself against the Pacha, and the British Ambassador near the Sublime Porte was instructed to demand his recall. This demand was supported by the intrigues of ambitious rivals at Constantinople. The present Seraskier Pacha, Husref, was then, and continues to be, one of the most embittered and untiring enemies of Mohammed Ali, to whom he attributes the revolt of the Albanians at Cairo, and his subsequent expulsion from the command of that capital.

The Sublime Porte yielded to the compound influence of foreign solicitation and domestic intrigue, and Mohammed Ali was ordered by an imperial *firman* to leave Cairo, and repair to Salonica (Thessalonica) to assume the administration of that Pachalet. He evaded obedience to the *Padischah's* firman, until important services supported by bribes judiciously distributed at Constantinople, induced the Sultan to reappoint him to the Pachalet of Egypt. He was deemed by the Imperial divan to

be the only man capable of governing that country, in the critical posture of affairs at that period.

French influence gained the ascendancy in the Ottoman councils in 1807, and Great Britain declared war against Sultan Selim and invaded Egypt. Mohammed Ali's troops met the British forces at Rosetta, and defeated them. They were subsequently compelled to evacuate Alexandria, which had capitulated to General Frazer. It was at this period that the British squadron, commanded by Admiral Sir John Duckworth, passed the tremendous batteries of the Dardanelles, and anchored off the city of Constantinople. The passage of the Dardanelles by an armed force, had never before, and has never since, been attempted. It was then that the navy of England could ask, *quæ regio in terris, nostris non plena laboris?* We may not forget, that some years before this signal event, our own Captain Bainbridge passed the Dardanelles, in his frigate the Washington, and displayed for the first time the star spangled banner in the Golden Horn.

The Sublime Porte was sensible of the important services rendered by Mohammed Ali, in the then war with England, and received frequent expressions of his Sultan's satisfaction, in rich and sumptuous presents. He continued to preserve his government against internal foes and foreign machinations. The Mamaluke Beys remained in arms against him, and carried on a desultory warfare. Mamaleuk Elfi Bey was supported by British influence.

On the 1st of March, 1811, Mohammed Ali succeeded in destroying the greater part of these refractory Beys, by a sanguinary and treacherous act, which has no parallel in any annals but those of eastern empires. It would be so judged by the rule of abstract morals, yet political necessity would sanction it in the east. The Pacha had not then studied Machiavelli, which he has in part since read. He had succeeded in conciliating those Beys to a certain degree, and had disarmed their fears and suspicions. About this period, the expedition against the Wahabees, the enemies of Islam, was preparing to leave Cairo. The departure of this expedition was made the occasion of calling together the civil and military authorities, under ceremonies becoming the occasion. The Mamaluke Beys were also invited to join the ceremonies and the procession which was to signalize the event. They obeyed the invitation, and were received with every demonstration of friendship, and with distinction suitable to their rank. Here then the Pacha had artfully succeeded in assembling, at the citadel of Cairo, the chief Mamalukes, to the number of four hundred, those early and formidable enemies, both to his personal aggrandizement and to the tranquillity of Egypt.

The citadel of Cairo, within which is the Pacha's palace, and the dilapidated, but once gorgeous serai of Selah-eddin, (Saladin) rests on a projecting shoulder of Mount Mokattam. From its frowning ramparts are seen, to the west, and beyond the Nile, the towering pyramids of Gizeh, and the lesser ones of Sakhara and Dashour; the allegoric sphinx lies couchant before you, as in centuries gone by, and the renowned Memphis is faintly distinguished by the few remains of her ancient glory, now concealed by clustering groves of the graceful palm. Immediately below the ramparts, reposes Cairo, the mother of the world, as she is called in the figurative language of Arabia, with her populous avenues, her tongues of Babel, sumptuous palaces, and more splendid mosques, and minarets. The silver stream of the "blessed" Nile, flows by the walls of Cairo, bringing fertility to the earth, and joy to its people.

From this citadel the military procession, led by Toussoun Pacha, who had been appointed to command the expedition against the Wahabees, moved, and in descending to the city, passed through a narrow passage or defile. On either side was the solid rock surmounted by high walls. When the Mamaluke Beys entered this defile, the gates at both ends were closed, and soldiers previously stationed for that object, commenced firing upon these unsuspecting victims of a treacherous design.—One Bey alone escaped from the horrible ambush.

The Pacha, a few years afterwards, replied to an allusion made to this dreadful massacre, that it would appear in history, along with the execution the Duke d'Enghien, by the great chieftain who had then filled the world, with the military glory of France.

An anecdote somewhat ludicrous, connected

with this tragic scene, may convey some idea of the indifference with which human life is regarded in the east, and the apathy of the Orientals to human blood. An European Consul asked an officer of the Pacha, who was witness to the massacre, if his feelings were not shocked. "Yes," he replied, "it was a pity to see so many embroidered dresses, rolling in the dirt." Another anecdote is told at Constantinople, of a Reis Effendi, who had lost his favorite circassian by the plague. The Dragoman of the Austrian Intendance, during an official visit to his Excellency, expressed himself in terms of condolence, for the painful event. "Yes it was a great loss," said the Effendi, "my *khanum* cost me one hundred purses."

The successful expedition of the Pacha, against the Wahabees of Arabia, the formidable enemies of the Moslem faith, established his reputation as a warrior. His claims to the consideration of the sublime Porte, and of the whole Moslem world, and secured his uninterrupted possession of Egypt. The war was concluded in 1813, by the capture of Derafeh, the Wahaba capital, and of their Chief *Abdallah-ebn-Souhoud*. The conduct of the war, which had been committed to Toussein Pacha, was subsequently entrusted to Ibrahim Pacha, Mohammed Ali's eldest son. By him the war was brought to a close, and Abdallah-ebn-Souhoud was sent to the Sultan, under the charge of Ismael Pacha, together with the few remaining objects of value, which was recovered from among those which Souhoud's father had plundered from the sacred shrines of Mecca and Medina. Of these the most remarkable was a copy of the Koran, so small as to have rivalled the Iliad of Homer, which Alexander carried about his person. There were also pearls and precious stones of unknown value, which pious veneration had bestowed as votive offerings, at the tomb of the Prophet. Abdallah-ebn-Souhoud was presented in chains at the foot of his sovereign, and Mohammed Ali had interceded in his favor, for imperial clemency. Sultan Mahmoud was relentless towards the chief of an heretical sect, which had for so many years defied his authority, desecrated the holy places of the Prophet, and interrupted the annual pilgrimages of the Moslem world, to the venerable *Cauha*, the waters of Zemzem, and the sacred sepulchre at Medina. Souhoud was publicly decapitated at Constantinople, in the open square, which may now be seen by the traveller, between the Porte of Sublimity and the Mosque of Santa Sophia.

The Wahabees, as a religious sect, have the same reference to the Mahomedan religion, which Socialism has to Christianity. The founder, Abd-ul-Wahab, was born in the last century, and after having studied divinity at Medina, and in the *Medressahs*, or theological schools of Bagdad, Basorah and Ispahan, he began to preach the novel doctrine, that the Prophet Mahomed was but a mere man, and that to invoke him with other saints, was idolatry, and was not authorized by the Koran. He adhered religiously to the text of the sacred book, but rejected all traditions, *Hadith* and the commentaries of the Imams or doctors. He contended that Mussulmans must be brought back to the original spirit of the Koran, to the exclusive worship of God, in his undivided unity. In this spirit, he forbade the pilgrimage to Mecca, the invocation of the Prophet, the use of luxuries, tobacco, opium, silk, and jewels. Following the example of the Prophet, he propagated his doctrines with the sword, and the armies of his successors marched upon Mecca and Medina, destroyed those venerable shrines, and robbed them of the unnumbered votive offerings, with which they had been enriched by piety and devotion.

Such were the doctrines of this warlike sect, which had for a long while contemned the spiritual, and defied the temporal, authority of the Sultan.

Relieved from this formidable enemy, Mohammed Ali was now at liberty to subjugate the southern provinces of Nubia, Sennaar, and Kordofan. These countries had for a long time, been in a state of anarchy and rebellion to the Government of Egypt. He accordingly, in 1820, sent an expedition of four thousand men, to those countries, under the command of his second son, Ismael Pacha, which resulted in the conquest of

those extensive provinces, with which Egypt has always had an important commerce. It was this expedition, which our countryman, *English*, accompanied. *Khalil Aga* of New York, was also attached to the army. We have another instance of the adventurous spirit of Americans, in one, who is at this moment, Governor of a District, within the territories of the Indian Prince, Runjeet Sing.

The Greek revolution commenced about this time, and Mohammed Ali prepared to obey his Sultan's *fermans*, and to furnish aid in troops, ships, and money. Whilst he opposed the movement of the Greeks, and contributed his efforts towards the suppression of their rebellion, it must be said in honor of his humanity, and in praise of his enlightened policy, that he did not imitate the massacre of these unfortunate subjects, who were residing at Constantinople. No Greek subject in Egypt was molested, and those who fled to that country were protected.

The friends of Greece, in Europe, did not so much fear the hostilities of the Sultan, as of the Pacha, in its struggle for independence. It is believed that this sentiment induced some of the greater cabinets to hold out to the Pacha the possibility of his independence, to withdraw him from combined operations with the Porte. Whether he distrusted Christian diplomacy, or was content to enjoy his *de facto* independence, he yet continued to furnish the principal means of operation against the Morea. The policy of European cabinets was for once imperfectly understood, and pertinacity caused the loss of the Egyptian squadron at Navarino, and the retirement of Ibrahim Pacha's legions from the peninsula.

The declaration of war against Russia in 1828, by the Sultan, was made contrary to the counsel of Mohammed Ali, and its result confirmed the wisdom of that advice. Causes of jealousy and dissatisfaction towards his Pacha continued to multiply in the mind of the Sultan; which found ostensible motives in the attack which Mohammed Ali made upon Abdallah Pacha of St. Jean d'Acre in 1831. The immediate origin of this war was the protection which the Pacha of Acre gave to the fugitive subjects of Egypt. Mohammed Ali asked not the intervention of the Porte, although he was equally its vassal with Abdallah Pacha. On the refusal of the Pacha to obey the mandate of the Porte, and to withdraw his troops from Syria, he was officially denounced by the Sultan as a rebel and outlaw. This sentence of excommunication from the Caliph or head of Islam, has as much force now, as had that of the Pope in the feudal ages.

The Sultan sent his forces into Syria, under command of Hussein Pacha, Beglerbeg of Anatolia, to oppose the advance of Ibrahim Pacha. Hussein was beaten in a pitched battle, and driven from Damascus to Hama, thence to Aleppo, and across the Taurus to Koniah. At this place the Grand Vizier, Reshid Mehemit Pacha, was made prisoner, in a sanguinary action, and the whole army of the Sultan became demoralized. Ibrahim Pacha might have marched upon Constantinople, but for the intervention of an armed Russian force, to protect the capital, and for the interference of European diplomacy.

In the city of Kutahieh, of Asia Minor, in the spring of 1833, the commissioners, envoys of England, France, and Russia, concluded an armistice and convention, for the evacuation of Anatolia. By this convention, with the consent of the Porte, Mohammed Ali received his confirmation to the whole of Syria, comprising the four Pachalicks of Aleppo, Tripoli, Damascus, and Saida, together with the province of Adana, which is of primary importance to Egypt on account of its timber. The news of peace was received at Alexandria, with demonstrations of public joy, and were attended with every species of festivity. The Pacha was compared to the "*Alexander of two horns*."

The negotiations that took place, and diplomatic notes that passed between Mohammed Ali and Admiral the Baron de Roussin, ambassador of France at the Porte, exhibit the true character of the former. He replied, in answer to the requisition of the Baron to withdraw his troops from Anatolia, "is not this pronouncing against me a sentence of political death? But I feel confident that France and England will not deny me justice. They will acknowledge my rights. Their honor is opposed to this step. But if I am unhappily deceived in this

expectation, I will submit myself, under such circumstances, to the will of God; and preferring an honorable death to ignominy, joyfully devote myself to the cause of my nation, happy to consecrate to it the last breath of my life. Upon this I am determined, and history offers more than one example of a similar immolation."

Mohammed Ali is now in the undisputed possession of Syria, Egypt, the Hedjaz of Arabia, Nubia, Sennaar, Kordofan, and the important Island Candia. That he will transmit his power and empire unimpaired to his successor in the dynasty, his past history justifies the belief. When he was invited to take supreme command in Egypt, thirty years ago, he said, "I have now conquered this country with the sword, and by the sword will I preserve it!"

Mohammed Ali is in person of middling, or rather low stature. He is now in his sixty-seventh year, and possesses a constitution sound and vigorous. His features are not those of the Osmanli, of Constantinople, where one may frequently find the *beau ideal* of manly beauty. The Tartar face, with its high cheek-bone, small eyes, and general flatness, which are peculiarly his, have been lost among the Ottomans, of the capital, by their marriages with the Greeks of Ionia, or the more languishing beauties of Circassia and Georgia. His dark gray eyes beam brightly with genius and intelligence, and his manners would be marked with more dignity, had they more repose. It would be difficult not to feel the presence of a superior man, when one is addressing Mohammed Ali. His dress, unlike that of Sultan Mahmoud, is not of the *mizam*, or reform. He still wears the turban, which the Sultan has abandoned, and this use of a most graceful head-dress will be approved by all persons of good taste. This remark applies only to the east. His dress is of plain olive colored cloth, without embellishment or decoration. At his side is always suspended a curved scimitar.

The Pacha is an early riser, and of abstemious habits. At the break of day he performs his orisons, and at sunrise, he repairs to his divan, for the transaction of business. After sunset he dines, and retires to his harem, where he either reads himself, or reclines on an ottoman, whilst one of his favorite Sultanas, the daughter of a mufti, and an accomplished woman, reads to him, by his instruction. He has lately been engaged in reading Montesquieu's *esprit des loix*, every successive sheet of which is prepared in manuscript by the translator, is taken by him to his harem, and becomes the occupation or relaxation of his evening. Machiavelli he read some years ago, and the code Napoleon is now the object of his deepest study and reflection.

This short sketch of the eventful life of Mohammed Ali, is not intended to exhibit the wonderful improvements which he has introduced into Egypt, nor the more wonderful personal superintendence, which he exercises over every department of the arts, and every branch of industry. It is hoped, that the impetus which he has given to civilization will not be checked, and that if his *de jure* independence should, in any manner, contribute to this desirable object, the conflicting interests of European and the Turkish cabinets, may be conciliated, and be directed to concur in such an acknowledgment.

*Mourning.*—In Europe, black is generally used because it represents darkness, unto which death is like, as it is a privation of life. In China, white is used, because they hope the dead are in heaven, the place of purity. In Egypt yellow is used, because it represents the decaying of trees and flowers which become yellow as they die away. In Ethiopia, brown is used, because it denotes the color of the earth from whence we came, and to which we return. In some parts of Turkey blue is used because it represents the sky, where they hope the dead are gone; but in other parts purple and violet, because being a mixture of black and blue, it represents, as it were, sorrow on one side, and hope on the other.

A person near London recently attempted to walk 7 miles in 60 minutes, and lost his wager by 30 seconds. He had 9 minutes 37 seconds to do the last mile in, but his strength was over tasked, and he failed in the attempt.

**Mechanical Skill of the Ancient Egyptians.**—The inner chamber contains subjects of the most interesting and diversified kind. Among these, on the left (entering), are cabinet makers, carpenters, rope makers, and sculptors, some of whom are engaged in levelling and squaring a stone, and others in finishing a sphinx, with two colossal statues of the king. The whole process of brick-making is also introduced. Others are employed in beating a liquid over a charcoal fire, to which are applied, on either side, a pair of bellows. These are worked by the feet, the operator standing and pressing them alternately, while he pulls up each exhausted skin by a string he holds in his hand. In one instance the man has left the bellows, but they are raised, as if full of air, which would imply a knowledge of the valve. Another singular fact is learnt from these frescoes—their acquaintance with the use of glue—which is heated on the fire, and spread, with a thick brush, on a level piece of board. One of the workmen then applies two pieces of different colored wood to each other, and this circumstance seems to decide that glue is here intended to be represented rather than a varnish or color of any kind.—[Wilkinson's General View of Egypt.]

**Principles of the Cotton Manufacture.**—Let us briefly review the different processes through which the cotton goes, in its conversion into cloth, all of which are performed in many of the large spinning and weaving mills. The cotton is brought to the mill in bags, just as it is received from America, Egypt, or India; and it is then stowed in warehouses, being arranged according to the countries from which it may come. It passes through the willow, the scutching-machine, and the spreading-machine, in order to be opened, cleaned and evenly spread. By the carding-engine the fibres are combed out and laid parallel to each other, and the fleece is compressed into a sliver. The sliver is repeatedly drawn and doubled in the drawing frame, more perfectly to strengthen the fibres, and to equalize the girth. The roving-frame, by rollers and spindles, produces a coarse and loose thread, which the mule or throstle spins into yarn. To make the warp, the twist is transferred from cops to bobbins by the winding machine, and from the bobbins to the spinning-mill to a cylindrical beam. This beam being taken to the dressing machine, the warp is sized, dressed and wound upon the weaving beam. The latter is then placed in the power-loom, by which machine, the shuttle being provided with cops of web, the cloth is woven. Such, without entering too much into the minutiae, are the processes by which the vegetable wool is converted into a woven fabric of great beauty and delicacy; and it will be perceived that the operations are numerous, and every one of them is performed by machinery, without the help of human hands, except merely in transferring the material from one machine to another. It is by iron fingers, teeth, and wheels, moving with exhaustless energy and devouring speed, that the cotton is opened, cleaned, spread, carded, drawn, roved, spun, wound, warped, dressed, and woven. The various machines are proportioned to each other in regard to their capability of work, and they are so placed in the mill as to allow the material to be carried from stage to stage with the least possible loss of time. All are moving at once, the operations chasing each other; and all derive their motion from the mighty engine, which, firmly seated in the lower part of the building, and apparently fed with water and fuel, toils through the day with the strength perhaps of a hundred horses. Men, in the meanwhile, have merely to attend on this wonderful series of mechanism, to supply it with work, to oil its joints, and to check its slight and unfrequent irregularities;—each workman performing, or rather superintending, as much work as could have been done by two or three hundred men sixty years ago! At the approach of darkness this building is illuminated by jets of flame, whose brilliance mimics the light of day,—the produce of an invisible vapor, generated on the spot. When it is remembered that all these inventions have been made within the last seventy years, it must be acknowledged, that the cotton mill presents the most striking example of the dominion obtained by human science over the powers of nature of which modern times can boast. That this vast aggregate of important discoveries and inventions should, with scarcely an exception, have proceeded from English genius, must be a reflection highly satisfactory to every Englishman.—[Gleaner's History of the Cotton Manufacture.]

**Platina.**—By a report in the Berlin State Gazette on the subject of platina, it appears that the quantity of ore extracted from the mines in the Ural Mountains, from the summer of 1824 to January 1834, was 230 quintals, two thirds of which consisted of pure metal. Of this, about 153 quintals were coined, amounting to a sum a little exceeding 8 million rubles. But little revenue had been derived from the mines, beyond the cost of the establishments. The coin is said to have thus far preserved an exact mean between the value of gold and silver.

**Christianity in Jerusalem.**—A Protestant church has been established at Jerusalem.—[There have been Catholic chapels in Jerusalem for more than six hundred years.]

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-1y febl4

#### STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads.

No. 264 Elizabethstreet, near Bleekerstreet, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J26 1f

#### NOTICE TO MANUFACTURERS.

SIMON FAIRMAN, of the village of Lansingburgh, in the county of Rensselaer, and state of New York, has invented and put in operation a Machine for making Wrought Nails with square points. This machine will make about sixty 6d nails, and about forty 10d nails in a minute, and in the same proportion larger sizes, even to spikes for shingles. The nails are hammered and come from the machine completely heated to redness, that its capacity for being clenched is good and sure. One horse power is sufficient to drive one machine, and may easily be applied where such power for driving machinery is in operation. Said Fairman will make, vend and warrant machines as above, to any persons who may apply for them as soon as they may be made, and on the most reasonable terms. He also desires to sell one half of his patent right for the use of said machines throughout the United States. Any person desiring further information, or to purchase, will please to call at the machine shop of Mr. John Humphrey, in the village of Lansingburgh. August 15, 1833. A29 (FRM&F

#### MILL DAM FOUNDRY FOR SALE,

The Proprietors of the Mill Dam Foundry offer for sale or lease their well known establishment situated one mile from Boston. The improvements consist of

No. 1. Boiler House, 50 feet by 30 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. Blacksmith's Shop, 50 feet by 30, fitted with cranes for heavy work.

No. 3. Locomotive House, 54 feet by 25, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with slate, 190 feet by 46, containing two water-wheels, equal to 40 horse power; Machine Shop, fitted with lathes, &c.; Pattern Shop; Rolling Mill and Furnaces, capable of rolling 4 tons of iron per diem, exclusive of other work; three Trip-Hammers, one of which is very large; Engine for blowing Cupola Furnaces, moved by water-wheel; one very superior 3 horse Steam Engine, which could be dispensed with; and a variety of other machinery.

No. 5. An Iron Foundry, 80 feet by 45, with a superior air Furnace and two Cupolas, Core oven, Cranes, &c. fitted for the largest work. Attached to the Foundry is a large ware-house, containing Patterns for the Castings of Hydraulic Presses, Locomotive and other Steam Engines, Lead Mill Rolls, Gearing, Shafts, Stoves, Grates, &c. &c. These were made of the most durable materials, under the direction of a very scientific and practical Engineer, and are supposed to be of great value.

No. 6. A building, 65 feet by 36, containing a large stock of chimneys, and furnaces, for making Cast Steel. This building is at present used as a boarding-house, and can accommodate a large number of men.

No. 7. A range of buildings, 300 feet long by 36, containing counting room, several store rooms, a Brass Foundry, room for cleaning castings, a large loft for storing patterns, stable for two horses, &c. &c.

The above establishment being on tide water, presents greater advantages for some kinds of business than any other in the United States. Coal and iron can be carried from vessels in the harbors of Boston, to the wharf in front of the Factory, at 25 to 30 cents per ton. Some of the largest jobs of iron work have been completed at this establishment; among others, the great chain and lift pumps for freeing the Dry Dock at the Navy Yard and Charleston.

The situation for Railroad work is excellent, being in the angle formed by the crossing of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at these works. With the Patterns and Machinery now in the premises, 12 Locomotives and as many tenders, besides a great quantity of cars and wagons, could be made per annum.

For terms, apply to

THOMAS J. ECKLEY, Treas'r &c., Boston, or to ROBERT RALSTON, Jr., Philadelphia. Boston, Dec. 30, 1834.

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMASTURNER, at the Factory, Troy, N. Y. sept. 12 7y

#### RAILWAY IRON.

65 tons of 1 inch by 1 inch,	Flat Bars in lengths of
200 do. 1 1/2 do. do.	14 to 18 feet, counter sunk
40 do. 1 do. do.	holes, cut at an angle
800 do. 3/4 do. do.	of 45 degrees, with splitting
500 do. 3/8 do. do.	plates and rails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Hubs of 20, 22, and 26 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 26, 28, 30, 32, 34, and 36 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. 47meowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, (54 Water street, corner of Market lane. J21 6t

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principle of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy;—also a Railroad Goniometer, with two Telescopes;—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes. WM. J. YOUNG.

Mathematical Instrument Maker, No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

Baltimore, 1832.

In reply to thy inquiries respecting the Instruments manufactured by these, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all Instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope; in place of the vanes which leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails;—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend, JAMES P. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most respectfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level. I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY M. CAMPBELL, Eng. Philad. Germantown, and Norristown, Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, MAY 2, 1835.

**TO CORRESPONDENTS.**—Our esteemed friend, L.—W.—, will very much oblige us by communicating the result of his experience. He should not withhold from the general fund, his share of the contribution, because he happens not to have enjoyed the advantages of education in the language of his adopted country.

It is the facts, and useful information, which his long experience enables him to give, and not the well turned sentences of a polished scholar, that we desire him to furnish us with. Let him, then, and others also, give to the world, through the columns of our Journal, the benefit of a well spent life in contributing to the improvement of the "ways" of their native, or adopted country.

**SARATOGA AND WHITEHALL RAILROAD COMPANY.**—The capital-stock (\$600,000,) having been readily subscribed on the opening of the books, the first directors named in the charter, consisting of Stephen Warren, Geo. R. Davis, Le Grand Cannon, James C. Hart, John Paine, Elias Pattison, Erasmus Corning, Lewis Benedict, John Townsend, John Knickerbocker, Geo. W. Kirtland, G. M. Davison, and Herman Gansvoort, organized on the 20th ult. by the appointment of the following officers, who hold until the first election of the stockholders in June next: Stephen Warren, President; G. M. Davison, Vice President; John Paine, Secretary; John Delafield,

Treasurer and Register of Transfers. Office in New-York.

We understand it is the intention of the Directors to cause this work to be commenced and completed without delay. The length of the road extending from Saratoga Springs to Whitehall, will be about 40 miles, over a very favorable country, not requiring stationary power. It will form an important link in the great thoroughfare from north to south; and when finished will, with the Lapeirrie and St. Johns, and Baltimore and Washington railroads, now in progress, afford an uninterrupted communication by steam between Quebec and Washington city, a distance of more than 800 miles! With such a facility, the northern travel, already heavy, will be greatly augmented, the intercourse with Canada increased, and the "northern tour" to summer visitants rendered double attractive. Indeed, when the Springs, Lake George, Montreal, and Quebec, can all be reached by steam, who will not be tempted to visit them? Certainly the road in question can hardly prove otherwise than a valuable and growing investment.

**DELAWARE AND ATLANTIC RAILROAD.**—Notice is hereby given, that the books for receiving subscriptions to the residue of the Stock of the Delaware and Atlantic Railroad Company, its price the Atlas opened at 1 o'clock, Philadelphia at the hour town; 6 o'clock, having Stock holders, and not of 14 m

The sum of \$5 on each Share is required to be paid at the time of subscribing.

**ON CANAL NAVIGATION, BY JOHN MACNEILL, ESQ.**—We have been favored by a scientific gentleman of this city with a treatise on the subject of canal navigation, or the "resistance of water to the passage of boats on canals," by John Macneill, Esq., member of the Society of Civil Engineers, London, which gives a series of results

that will appear incredible to those who are not familiar with great speed in canal navigation. There are many persons who will require further evidence before they will believe that navigation can be carried on on canals at the rate of 10 to 14 miles per hour, without injury to the banks and that too on a canal narrower than the canals of this State; and many others who will hardly credit the theory, that the resistance will be less on a narrow than broad canal; yet such appears to be the opinion of those who have examined the subject, and expounded upon it. We shall continue our extracts from the work.

The engravings at page 260 are designed, figure 1 to give an idea of the reservoir and apparatus with which the numerous experiments described in this number were made by Mr. Macneill, figure 2 represents the boats now in use on the Paisley canal—a full description of which will be given in our next; fig. 3 shows a transverse section of the Paddington canal, breadth 56 feet, and greatest depth 4 feet 8 inches.

The following is the introduction of Mr. Macneill:

The results which I have arrived at by experiments are so much at variance with generally received theoretical deductions, that it is with much diffidence I submit these pages to the consideration of the public, and to those more immediately concerned in Inland Navigation. The following observations are made with a hope that those discrepancies between theory and practice may tend to a more rigid adherence to experimental inquiries in other branches of practical science; but especially, that they may lead to a more varied and extensive series of experiments to ascertain the best form of boats, not only at the cost of public companies, whose canal property may well demand it, but also at the expense of government, who pay out large sums in steam navigation; for I trust it is clearly shown, that very great alterations and improvements may be made in the models of all ships and boats which are not impelled by the wind, and that passengers and light goods may be carried by canals at a velocity hitherto supposed to be impracticable.

**On the Resistance of Water to the Passage of Boats on Canals, &c.**

The laws which regulate the resistance and impulse of fluids are involved in such obscurity, that could investigation of this

Appointed a director in place of P. J. H. Myers, deceased.

branch of science are compelled to confess, that the dissertations of the physico-mathematician have failed in utility, and that even the deductions of the logician have been almost altogether ineffectual. The assumptions of the former, from which propositions have been deduced, and theories given out, are, at best, founded only on an hypothesis; the reasonings of the latter rest upon limited experience, and, in some cases, ill observed phenomena. And there is probably no branch of science which has so much engrossed the attention of the philosopher, and from which so little practical good has resulted.

That such is the fact, and that the farther the subject has been investigated, the more difficulties have been met with, if not always acknowledged, few can venture to deny.

If, in his zeal for information, the inquirer of the present day searches the shelves of philosophy, his labor will terminate in the settled conviction, that this branch of science is but yet in its infancy, even although illustrated by the novel algebraical calculus, and the beautiful results derived from it by French ingenuity. A long course of patient experiment will alone warrant the adoption of formulae; for as yet, as far as regards the mere resistance of the fluid, the practical application of the laws founded by the mathematician, has failed in producing any form which will rival the skiff of the Indian, the canoe of the Esquimaux, or the junk of the Chinese.

These observations apply to all boats and ships impelled by any other force than the wind; and this must not be forgotten, whilst we proceed to examine one particular department, viz. canal navigation. Every body moving in or upon the water, it will be seen, is under similar laws; and although the following remarks are applicable to every mode of conveyance, we will confine ourselves to the canal.

The object in we place a boat a good conveyance. So is it when we upon a gravelle snow. The dif modes of attain most striking. In each of these cases, the body to be moved has been rested on soft or yielding matter, and whilst, in the two latter cases, no mechanic would provide for the wheels of the carriage, or the runners of the sledge, a facility for cutting along, immersed in the softer matter under them, the boat-builder seems to have studied how he could best keep his vessel ploughing her way. The case may be different with sea-going vessels, which are impelled by the action of a wind "on the beam load," is no immov be in ble t! But there a sh be as unphilosophical as a knife-edged fel-los would be to a wheel intended for ploughed land. A cart-wheel will, on gravel or other yielding matter, sink to the determined line of gravitation with as much certainty as will a boat upon water; and a boat resting in water will (according to the velocity given to it, and the form of its prow and bottom,) rise nearer the surface of the water, as well as a cart-wheel will rise

when put rapidly into motion. The difference of density is, no doubt, much greater in one case than in the other; but the water will resist the penetration of the boat in the same manner, though not in the same degree, as the soft gravel or mould resists the wheel. Notwithstanding a conclusion so obvious to those who know the laws of gravitation, and the properties of matter, so easily calculated by every one who understands any thing of the combination of forces,\* we find it has been neglected in order to determine what law regulates the movement of a body immersed to the same depth, at all velocities.

At a time when it was generally held, that the resistance to a vessel in the water increased in the duplicate ratio of the velocity of the vessel through the water, the now keenly contested merits of railway transport, and canal transport, were brought under public discussion. Experiments were instituted in order to confirm this law of resistance, but it occurred to none of the experimentalists that, although they could not increase the density of the water, or harden it, as has been done with roads for carriages, that they could still increase the relative resistance of water, by giving the boat such velocity that her prow could not penetrate fast enough, and thus that she should rise out of the fluid. They might have reasoned, by a perfectly fair analogy between conveyance on land or on snow, and conveyance of water, and have legitimately concluded that, as their object was not to cut through gravel, but to get on it, in the one case, so at high velocities in the other, they should not have endeavored only to cut through the water, but also to raise the boat to the surface, and make her skim thereon.

Such facts are obvious to all, who have seen a boy make a thin stone skim the surface of a lake,—who have watched the action of a cannon ball on the smooth sea,—who have felt the difficulty of making any impression upon the stream forced from the small aperture of a fire-engine's hose-pipe,—or, indeed, who know any thing of the properties of matter; but they had never been applied to the purposes of navigation, until it occurred to Mr. Houston, of Johnstone Castle, to try the effect of a light gig-shaped boat upon a canal; and it is very surprising that the most strenuous advocates for the adoption of such boats still reject the above facts, as irrelevant. It matters not whether the water be forced against the object, or the object be forced against the water.

In the month of June, 1830, Mr. Houston succeeded in having a light, long, and shallow wrought-iron canal boat, established upon the Ardrossan canal, in Scotland, between Paisley and Glasgow. Since that period, such boats have continued to run regularly, conveying about sixty passengers a distance of "twelve miles, at a rate of eight miles an hour, stoppages included." Succeeding improvements in the construction of the boat, as well as in the mode of working the horses, enable us to state the above as a minimum of performance. In the Appendix (A) will be found a specification of one of such boats, and Plates III.

\* We find a good illustration of this resistance in "A Winter in Lapland and Sweden by Arthur de Capell Brooker, 1737," p. 338.—"The real superiority of the skis is chiefly shown when the enemy halt after a long march. Whatever precaution may then be taken, they are in constant danger from troops which have no occasion for path or road, and traverse with indifference marshes, lakes, rivers, and mountains. Even in those parts where the ice is too feeble to bear the weight of a man, the skis glide easily over, by the mere rapidity of his motion."

IV. and V. show their form and dimensions. The following quotation from the advertisements, the truth of which is well authenticated, shows the cheap rate of conveyance.

	Distance.	Cabin.	Stowage.
"Fare between Glasgow and Paisley.....	8 miles.	3d.	3d.
Fare between Glasgow and Johnstone.....	12	18	9
Fare between Paisley and Johnstone.....	4	5	3

Intermediate distances as in the way-bill.

"The boats, at times, carry twelve hundred passengers in one day; and during eight months of last year, (1832,) notwithstanding the prevalence of cholera, they conveyed one hundred and twenty-six passengers, which is at the rate of fifteen thousand seven hundred and fifty, monthly."

Mr. Thomas Grahame, in his "Letter to Canal Proprietors and Traders," says, "The experiments of great velocity have been tried and proved on the narrowest, shallowest, and most cursed Canal in Scotland, viz. the Ardrossan or Paisley Canal, connecting the city of Glasgow with the town of Paisley and village of Johnstone, a distance of twelve miles." The result has disproved every previous theory as to difficulty and expense of attaining great velocity on canals; and as to the danger or damage to the banks of canals by great velocity in moving vessels along them.

"The ordinary speed for the conveyance of passengers on the Ardrossan canal, has for nearly two years been from nine to ten miles an hour, and although there are fourteen journeys along the canal per day, at this rapid speed, the banks of the canal have sustained no injury."

The boats are formed seventy feet in length, about five feet six inches broad, and, but for the extreme narrowness of the canal, might be made broader. They carry easily from seventy to eighty passengers, and when required, can, and have carried upwards of one hundred and ten passengers. The entire cost of a boat, and fittings up, is about £125. The hulls are formed of light iron plates and ribs, and the covering is of wood and light oiled cloth. They are more airy, light, and comfortable, than any coach. They permit the passengers to move about from the outer to the inner cabin, and the fares per mile are one penny in the first, and three farthings in the second cabin. The passengers are all carried under cover, having the privilege also of an uncovered space. These boats are drawn by two horses (the prices of which may be from £50 to £80 per pair) in stages of four miles in length, which are done in from twenty-two to twenty-five minutes, including stoppages to let out and take in passengers, each set of horses doing three or four stages alternately each day. In fact, the boats are drawn through this narrow and shallow canal at a velocity which many celebrated engineers had demonstrated, and which the public believed to be impossible."

Mr. Grahame then proceeds making apparent his want of confidence in railways—"The entire amount of the whole expenses of attendants and horses, and of running one of these boats four trips of twelve miles each (the length of the canal) or forty-eight miles daily, including interest on the capital, and twenty per cent. laid aside annually for replacement of the boats, or loss on the capital therein invested, and a considerable sum laid aside for accidents and replacement of the horses, is 700l. some odd shillings, or taking the number of working days to be three hundred and

twelve annually, something under 21. 4s. 3d. per day, or about 11d. per mile. The actual cost of carrying from eighty to one hundred persons, a distance of thirty miles, (the length of the Liverpool railway,) at a velocity of nearly ten miles an hour, on the Paisley Canal, one of the most curved, narrow, and shallow canals in Britain, is therefore just 11. 7s. 8d. sterling. Such are the facts, and incredible as they may appear, they are facts which no one who inquires can possibly doubt."

The following is a statement I am enabled to publish showing the gross expense of running old heavy boats on the Paisley canal at the rate of four miles per hour, and new light boats on the same canal at the rate of ten miles per hour, and the comparative expense per mile; also the number of passengers carried before and after the introduction of the high and cheap speeds.

Speed per hr.	Number of boats	Number of passengers each day.	Whole cost per week.	Cost per mile, year, taken at 110 days.
1830* . . 4	2031	46	700l. 4s. 7d.	11d.
1831† . . 10	79455	vary'g	13144. 17s. 3d.	—
1832† . . 10	140516	156	918l. 5s. 11d.	104d.

The power of conveyance thus established on the Paisley canal, may be judged of from the fact that on the 31st of December, 1832, and 31st of January, 1833, there were conveyed in these boats nearly 2,500 passengers.

The number of passengers continue to increase. The number carried in April, 1833, was twenty thousand, or at the rate of two hundred and forty thousand yearly.

It does, therefore, appear surprising, that canal owners in particular, whose property was daily becoming less valuable in the share market, by the alleged superiority of railway conveyances, should have been so blind or supine as to allow nearly three years to pass over, without making vigorous efforts to follow the successful example; but it is not the less true that they were, and indeed are still so; although, if the system be a good one, and practicable, and lucrative, as to me it appears undoubtedly to be, they could not have hit upon a more happy arrangement for keeping up their dividends, and for improving their property to a greater extent than it has arrived at, since the commencement of canal navigation in England. In many situations throughout the kingdom, where the quick transit of passengers, and even of light goods, was of consequence, it would not only enable the canal companies to compete with existing turnpike roads, but also to supersede the necessity for railways for general purposes.

We must suppose that canal proprietors did not credit the various reports in circulation as to the speed at which the boats were drawn upon the Paisley canal, the ease with which horses perform their work, and the small surge produced on the sides of the canal. But even supposing many of these reports to be exaggerated, and that false conclusions were come to by those who witnessed the performance, the great points of speed and economy were established to the satisfaction of many inquirers. Had the facts been known to canal proprietors, we should have expected the institution of a series of experiments long ere this, for ascertaining the actual resistance of boats at high velocities, and under every

variety of circumstance, as well as the best form of boat suited to those velocities; the height of the wave or surge, as well as its character and effects, and many other important features, which were now for the first time exhibited.

It is most unaccountable why canal companies did nothing to determine such; and it is to be hoped they may now be induced to institute extensive experiments. The few experiments which are detailed in the following pages, though made with as much accuracy as circumstances would admit, and though they are conclusive on some points, are by no means as extensive and varied as the importance of the subject demands. The scale of expenses was so exceedingly limited that they could not be carried farther, and others of still greater importance have not, in consequence, been undertaken, and remain yet to be made.

The energy and inquiring habits of Mr. Telford would not let such a practically useful inquiry remain dormant. He therefore directed me to make some preliminary experiments on a small scale, and to his liberality we are indebted for the first series, which were made entirely at his expense, in the National Gallery of Practical Science in Adelaide street; where the arrangements of the room were so admirable, and the accommodation, which the managers of the Gallery always gave for uninterrupted experiment during three weeks, was such,\* that the most accurate results were obtained on a limited sheet of paper.

Plate (I.) represents the plan and elevation of the reservoir of water in the National Gallery of Practical Science in Adelaide street, with the apparatus which was fitted up by Mr. Saxton, for the purpose of making the experiments. The straight part of the reservoir is seventy feet long, and four feet wide, with upright sides. The wheel and axle, B & b, were of excellent workmanship; the axle on which the weight acted was of hard wood, three and a half inches in diameter, and the wheel on which the line that pulled the boats was coiled, was of brass, thirteen inches in diameter; the axis on which the wheel and axle turned was of polished steel, half an inch in diameter, working in brass. The pulley or sheave F, f, which was attached to the tin box or can, C & c, which held the weights, was of brass, two and a half inches in diameter, and its axis was of steel, with conical points working in brass. The line used for the weight was of cat-gut, one eighth of an inch in diameter, and the lines used for pulling the boats were, in some of the experiments, of silk, in others hemp, varying in thickness from one fortieth to one twentieth of an inch in diameter. The tension of the line in each exp was exerted on placed in the bucket, and was then drawn to the farther end of the reservoir; the required weight was put in the bucket, and on a signal being given, the boat was disengaged, and drawn by the weight in the bucket to the opposite end of the reservoir, where it was stopped by a bag of cork shavings (j). In some of these experiments an additional weight was allowed to act on the boat for the first twenty feet, in order to get up the velocity; then it was cut off, and the boat went on with the uniform velocity; this was accomplished by putting a ring of lead (s), weighing 20 pounds, on the top of the bucket holding the weights, and making this ring fast by

\* Every gentleman who witnessed the experiments, and saw the facilities with which the Committee and their manager, Mr. Payne, gave, agree with me in bearing testimony to the liberal and philosophical spirit with which we were aided. They not only allowed a large portion of the gallery to be set apart, and put themselves to considerable inconvenience, but showed the free admission of all persons interested or wishing in the experiments.

In making some preliminary experiments it was found that a considerable space was necessary to be passed over by the boats, from the point of starting, before they acquired a uniform velocity. It was therefore found necessary to limit the distance over which the uniform motion was measured, to a space of fifty feet, and consequently, great accuracy was necessary in determining the time of the boat's transit over so short a space. I therefore applied to my friends, Messrs. Arnold and Dent, the celebrated chronometer makers, in the Strand, who, with that liberality which usually accompanies science, not only furnished me with chronometers, but Mr. Dent himself, more than once, assisted in measuring the time, and comparing it with that observed by Mr. Turnbull and Mr. Burns, whose accurate and careful observations have contributed so much to the success of these experiments.

Occasionally two, and sometimes three chronometers were used, placed as at (A, A,) on brackets, screwed to the side of the reservoir, at the commencement and at the end of the measured space.

Closely to these chronometers, and exactly at fifty feet apart,\* two brass wires were stretched across the reservoir, at eight inches above the surface of the water; by means of which wires the observers could determine the exact instant of time that the bow of the boat came under them, as they were slightly touched by a slender piece of brass wire, rising perpendicularly from the stem of the boat.

In some of the first experiments it was found extremely troublesome to ascertain the exact interval of time of the boats passing between the wires, in consequence of the chronometers having different rates of going; but this difficulty was obviated by a suggestion of Mr. Cubitt, who proposed that after a certain number of experiments, the piece of the chronometers should be changed, and the experiments repeated. This effectually obviated the difficulty, and enabled us to get the time with great precision. In the latter experiments, only one chronometer was used; it was placed on the bracket at the first wire, and a line was brought from the second wire, along the side of the reservoir, up to the point: by which means, the observer, holding the line in his hand, and keeping his finger on the wire next him, was enabled to maintain dry the touch, the pass wire, and the wire between each wire of boats of the moments were five times noted by communicating until each series they were taken.

In making the experiments, the line was made fast to the stem of the boat, which was then drawn to the farther end of the reservoir; the required weight was put in the bucket, and on a signal being given, the boat was disengaged, and drawn by the weight in the bucket to the opposite end of the reservoir, where it was stopped by a bag of cork shavings (j). In some of these experiments an additional weight was allowed to act on the boat for the first twenty feet, in order to get up the velocity; then it was cut off, and the boat went on with the uniform velocity; this was accomplished by putting a ring of lead (s), weighing 20 pounds, on the top of the bucket holding the weights, and making this ring fast by

\* In most of these experiments this distance was reduced to 25 feet, as shown in the "general plan."

\* These charges are the bare outlays.

† These charges include loss on purchase and sale of additional horses, and ten per cent. on cost of horses, boats; deposited in a contingent fund.

four lines to the upper frame work, these lines being of sufficient length to allow the ring to act on the bucket, and to descend with it through a given space.

TABLE I.—Experiments made with different models over the sheet of water in the National Gallery of Practical Science, London, for the purpose of ascertaining the law of resistance, or force of traction at different velocities.

The boat used for the experiments was 10 ft. 2 inches long, 8.5-10 inches broad at water level, 3.5 inches deep, and when empty immersed 1.5 inches, and weighed 22.19 lbs.

In the first series of eight experiments, 17.06 lbs. of shot were placed in the centre of the boat, making its weight 39.25 lbs., and a line made fast to the boat, extended the length of the reservoir of water, and over a pulley, with one lb. weight attached to it. The length of the canal or reservoir in which the experiments were formed was 70 feet; but the space marked out to be passed over with a uniform velocity was 30 feet; the first part of the space being used merely to attain headway. The shortest period of passing the 30 feet marked off was 9.4-10, and the longest 10 seconds, giving an average rate of 2.069 miles per hour—with a force of traction or weight on the towing line during each experiment of 0.466 lbs.

and an average difference of +0.40 between theory and experiment.

In the second series of eight experiments, boat, load, and distance same as above, with 5 lbs. weight attached to the cord—the time was 7.0—7.0—7.0—7.0—7.20—7.4—7.0—7.0 seconds, and the average velocity 2.802 miles per hour—and the force of traction, or weight on the towing line, during each experiment, 1 lb., with a difference between theory and experiment of -0.102.

In the third series of eleven experiments, the boat, load, and distance same as in the first and second series, with 10 lbs. attached to the cord, time in seconds of passing the 30 feet with uniform velocity was 6.2—6.2—6.0—6.4—6.2—6.2—6.4—6.2—6.0—6.2—6.4—with an average of 3.290 miles per hour, and a force of traction of 1.718 lbs.—or weight on the towing rope during each experiment, giving a difference of -0.556 between theory and experiment.

In the fourth series of ten experiments, boat, load, and distance same as above, with 20 lbs. weight attached to the cord; the time in seconds of passing 30 feet was 4.0—4.2—3.8—3.4—4.0—4.0—4.0—3.8—4.0—4.0 seconds, or an average of 5.232 miles per hour, with a force of traction, or weight on the towing line during the experiments—giving a difference of -0.316 between theory and experiment.

In the fifth series of nine experiments, boat, load, and distance same as in preceding, with 40 lbs. weight attached to the cord, the time in seconds of passing 30 feet was as follows: 2.8—2.8—3.0—2.8—3.0—2.8—2.8—2.8—2.8 seconds, or an average of 7.196 miles per hour, with a force of traction, or weight on the cord, of 5.912 lbs. during each experiment, and -0.261 between theory and experiment.

In the sixth series of six experiments, boat, &c., as in preceding experiments, with 60 lbs. attached to the cord, the time of passing 30 feet was as follows, viz.: 2.2—2.0—2.2—2.2—2.0—2.0 seconds, or an average of 9.607 miles per hour, and force of traction of 8.500 lbs. on the towing line during each experiment—with a difference of +1.412 between theory and experiment.

In the seventh series of three experiments, weight of boat and cargo 55.06, distance 30 feet, with 10 lbs. weight attached to the cord, the time of passing 30 feet was as follows, 7.0—7.2—6.8; making an average of 2.982 miles per hour—force of traction, or weight on the towing line 1.718—giving a difference between theory and experiments of -0.800.

In the eighth series of five experiments, boat, cargo and distance, same as in preceding series, with 20 lbs. attached to the towing line, the time of passing 30 feet was as follows: 5.4—5.2—5.4—5.4—5.2—ma-

king an average of 3.845 miles per hour, with a force of traction, or weight on the towing line, of 3.156; making a difference between theory and experiments, of -1.568.

In the ninth series of eight experiments, the boat weighing 22.19 without load, the distance passed over, and weight attached to towing line, same as in the preceding, time of passing 30 feet was as follows, viz.: 3.0—3.0—2.9—3.2—3.1—3.2—3.0—3.2—at an average rate of 6.600 miles per hour, with a force of traction, or weight on the towing line during each experiment, of 3.156; making a difference between theory and experiment, of +1.608.

In the tenth series of four experiments, or from the 69th to the 72d; the boat, distance, space and weight, attached to the rope same as in preceding, the time of passing over 30 feet was as follows, viz.: 3.0—3.0—3.1—3.0, at an average rate of 6.763 per hour, with a force of traction, or weight on the towing line, of 3.156; making a difference between theory and actual experiment of +1.756. In this series, an additional 10 lbs. weight was added for the first 30 feet of the canal, to bring the boat to her full speed, before reaching the measured space of 30 feet.

In the eleventh series of seven experiments, or 73 to 79 inclusive, the boat, load and space passed over, same as in the first series, with a weight of 20 lbs. attached to the line, the time of passing 30 feet was as follows, viz.: 3.4—3.6—3.8—3.4—3.6—3.6—3.8, at an average rate of 5.601 per hour, with a force of traction, or weight on the rope, during each experiment, of 3.156, giving a difference between theory and experiments of +0.322. In this series an ac-

celerating force of 10 lbs. was added during the first 20 feet of the canal.

In the twelfth series, or from 80 to 82 inclusive, boat, load, space and power, (except the 10 lbs. additional,) as in the preceding time as follows: 3.8—4.0—3.8, with an average of 5.392 per hour, and a power of traction of 3.156, and a difference of -0.034 between theory and experiment.

In the thirteenth series, from 83 to 87 inclusive, boat, load and space, same as in preceding, with 40 lbs. weight, (and 10 lbs. additional to 86 and 87,) the time in passing the thirty feet, was as follows, viz.: 2.8—2.7—2.7—2.7—2.7—with an average speed, of 7.521 miles per hour, force of traction of 5.812; making a difference between theory and experiment, of +0.263.

In the fourteenth series, or from 88 to 92 inclusive, boat, load and space, same as in preceding, with 70 lbs. attached to the rope, the time of passing over the 30 feet was 1.9—1.9—1.8—1.6—2.0—with an average rate of 11.180 miles per hour, power of traction 9.863; making a difference between theory and experiment of +3.561.

In the fifteenth series, from 93 to 101 inclusive, boat and space, same as in preceding, and in No. 1, with 80 lbs. attached to rope, the time of passing 30 feet was as follows: 1.9—1.8—1.8—1.8—1.8—1.6—1.6—1.6—or an average of 11.928 miles per hour, and a power of traction of 11.217, and a difference between theory and experiment of 4.063.

The following experiments are given in full as contained in the table, and not, as in the previous descriptions, in a condensed form.

I call attention particularly to these individual experiments, in order that the wide deviation may be noticed, and serve to shake the confidence still entertained by the adherents of the old school, who cannot allow that a high velocity is attainable upon canals with economy. Not that I consider the old law of the squares to be incorrectly stated; in so far as the boat remains immersed in the water to the same water line, that law may be correct; but that whenever the velocity of the boat is increased beyond a certain point, as will be seen hereafter, the boat emerges a little out of the water, and skims nearer the surface. The transverse section of immersion being lessened. This will be proved as we proceed.

Such facts being obtained and found to differ so widely from the opinions of philosophers, it was exceedingly desirable that they should not go forth to the public without the fullest confirmation. Happily for science, Colonel Page, Chairman of the Kennett and Avon Canal Company, to whose exertions and liberality it is entirely owing, induced the principal canal companies in England\* to subscribe towards paying the expenses of an extended course of experiments with a large boat. I accordingly proceeded to Scotland, and purchased one of the Paisley Canal Company's quick boats, "the Swallow," which we afterwards named the "Grahame and Houston," in compliment to the two gentlemen who have been so eminently successful in improving the canal conveyance of Scotland. Indeed, Mr. Grahame's letters on the subject of canal navigation will furnish the most satisfactory reason why we should have used his name for the boat.

\* The Grand Junction, the Kennett and Avon, the Aire and Calder, the Oxford, and the Leeds and Liverpool.

The National Intelligencer says: We refer those who are interested in such undertakings, to the invitation to contractors, given by the Georgia Union Railroad Company, in this day's paper. Lest any persons in the northern parts of the Union, disposed to offer for the contract, may be deterred by apprehensions of unhealthfulness of the country through which the road passes, we think it proper to state that the route of the road pursues the elevated ridge separating the waters falling into the Savannah river from those falling into the Ogeechee and Oconee rivers, and is presumed to be as healthy as any tract in the Southern country. The length of this road is 75 miles, and it is intended to extend branches to Athens and to Madison, making in all 145 miles of railway.

The New-Brunswick Fredonian says, that Railroad Stocks are all the go now-a-days, among the speculators and capitalists. A few days since books were opened in Philadelphia for subscription to the stock of the Lancaster, Portsmouth and Harrisburgh Railroad. In thirty-one minutes every share was taken, and a large number applied for beyond the ability of the Commissioners to supply.

The stock of the New-Jersey Railroad and Transportation Company is gradually advancing to its real value. It is eagerly sought after now at 126, and will, it is believed, not stop much, if any, short of 200! The stock of the Camden and Amboy Railroad is also selling at an advance of something like fifty per cent.

It is stated by the Belfast, Maine, Advocate, that there will be sawed on the Penobscot this year, one hundred and fifty million feet of boards—worth at the mill about \$1,000,000 of dollars.

It will be observed in the above tables, that as the velocity was increased, the power did not require to be increased in any thing like the duplicate ratio, and that the difference shown in the above column, betwixt the theory of the duplicate ratio and the actual experiments becomes greater as the velocity is increased. I select from these experiments the following as instan-

ces. They are not taken from the means, but from the items of the experiments themselves.

At a velocity per hour of

2.703 miles, 1. lb is required, or .180 more

than the theory of the square.

**Central-discharging Water Wheel,**  
New-York, March 18th, 1865.

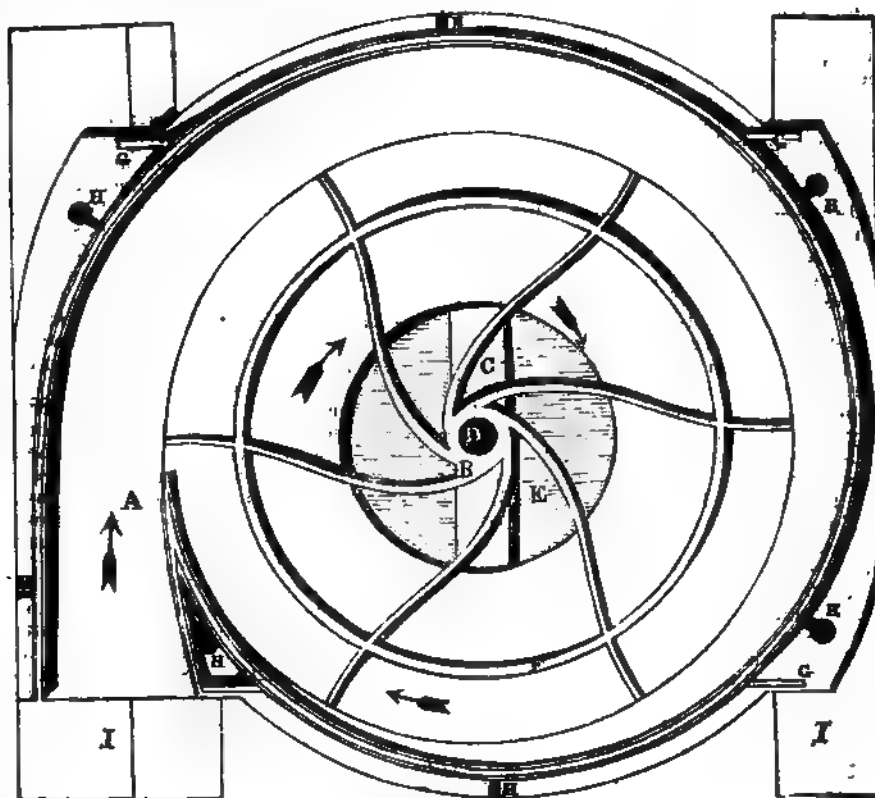

To the Editor of the *Mechanics Magazine*:

Sir,—I herewith forward you a drawing of Joel Eastman's Central-discharging Water Wheel, patented lately. The inventor died before he had brought it to that degree of perfection it has now attained. The undersigned being a joint patentee, has devoted considerable attention to this wheel, in order that he might present it to the public for their patronage, in a form that would do them, and the wheel itself, justice. This, he thinks, has now been fully attained. During the last year, many of them have been built and put in motion in the western part of New-York, with a degree of success unprecedented. The wheel is adapted to all degrees of head and fall. It runs as well in backwater as out of it, the head being the same. In cold climates, where the ice is troublesome, this wheel is a relief from the difficulty, as it can be so placed that ice cannot form near it. It may be wholly buried in water to effect this object; in which case the shaft must be surrounded with a water-tight case, to prevent the water from coming into the wheel around the shaft, as that would injure its action.

In many instances this wheel has been put in comparison with those before in use, and in every instance the comparison has been very much in its favor. A few facts on this point will be stated in this place, believing they will be acceptable to your readers, and especially interesting to mill owners.

The first wheel which the undersigned put in operation was for Messrs. Ford & Chapman, Clyde, Wayne County. The head and fall in this case was 4 feet; it took the place of a reaching wheel, and was designed to carry two large double carding machines, pecker, and a grindstone. The wheel was made of wood, 4½ feet diameter, 4 arms, or floats, morticed through the shaft, 12 inches wide. The throat was 8 inches wide, and 12 inches high, = 96 square inches area of water. The reaching wheel had 12 openings, whose aggregate area amounted to 336 square inches. In this place it should be remarked, that, from the peculiar nature of this wheel, it does not expend the water so fast under the same head and aperture, as in the case of the wheels in common use. When the wheel runs light, or without a load, the difference is one half; in other words, only half as much water is expended as would flow through the same aperture when the wheel is removed out of the way. This has been ascertained by experiment. When the wheel is charged with its ordinary load, the expense of water is one third less than if discharged under the same head and aperture on an undershot wheel; so that in the case above, where the aperture was 96 inches, the expense was only equal to 62 inches.

When this wheel was set to work, it was found to exert more power than the reaching wheel, which the millwrights in this case judged consumed from four

to six times as much water. When the operation of fulling commenced, this wheel was found able to finish a stock of cloth in six hours that used to require eight hours by the reaching wheel. This wheel was built and put in motion in three days by four men, and, as may be supposed from the above statement, gave great satisfaction. The proprietors, among the most intelligent mill owners in the State, unsolicited, have furnished me with a statement of the performance of this wheel, certified.

Another wheel was put in motion in Eldridge. It took the place of a tub wheel, 6½ feet diameter, which received 280 inches of water. This wheel was 5 feet 10 inches, used just one half of the water required by the tub wheel to drive a pair of heavy rock cornstones, and with one half the water it ground faster.

In Courtland County, there are about

20 of these wheels in use, generally with a head and fall of about 5 feet, on a stream very sluggish, and in time of floods the head is sometimes reduced to 16 inches; still the wheel goes, though with less power, bearing a just proportion to the head and fall. The general rate of the performance of this wheel is, that it requires only half the water used on the ordinary undershot, tub, and flutter wheels, and about one third less than a low breast wheel; and, as it is known that the overshot wheel doubles the working effect with some water and head used by the undershot, it follows from analogy that this wheel (being found to do the same) is equal to the overshot in its effect. It has not been tested against an overshot wheel, except in one instance, a common country mill; in this case it exceeded the overshot in effect, but it is not considered a satisfactory experiment. The under-

signed, however, is so well convinced that it will equal the overshot in its performance, that he would not hesitate to put it to the test under a heavy forfeiture.

Millwrights, generally, when they first see the plan, are inclined to treat it with utter contempt; which, in every case that has come under observation, has been subdued. When they have seen the wheel at work, they uniformly give it up, and admit that it excels all other wheels for low heads, although its being so small and simple puzzles them to account for the effect.

This wheel is also well adapted for saw-mills. When used for this purpose, the shaft is usually placed horizontal, and the wheel vertical. If the head is less than 6 feet, then the best way to apply it to sawing is to form the wheel of its usual size, varying from 4 to 6 feet, according to head and fall, and gear to the crank shaft by two small bevel wheels. There are several saw mills in operation on both of these plans; that is, when the motion is given directly to the crank shaft by the wheel being on it, and by gearing. The accompanying drawing represents one of these wheels, made entirely of cast iron, except seven screw bolts, to secure it in its place upon a foundation of bed timbers. Fig. 1 represents a plan. Fig. 2, a view of the same in perspective. The circle in which the wheels revolve is  $4\frac{1}{2}$  feet, about medium size. Fig. 3 shows the wheel in its place, the floats being connected and supported by a ring of iron near their extremities. A represents the throat, by which the water is admitted, 10 wide by 18 high, forming an aperture of 180 square inches. B on the plan represents the wheel; C, the bed piece, supporting the step of the shaft; D, the shaft; E, the opening in the bottom of the case containing the wheel, by which the water is discharged, 2 feet in diameter, equal to 452 square inches. The general rule is, to make the discharging circular opening about four times the dimensions of the aperture by which the water is admitted on the wheel. F, the ring of support to the floats. G G G, brackets to add strength. H H, &c., holes and notches, to admit of bolts to secure the whole together, and to the bed timbers, I I.

The top of the case, in which the wheel revolves, is not shown in the drawing; it is made to fit on the top edge of the rim, forming the spiral exterior of the wheel; a groove of slight depth is formed in it, to admit of making it tight. The throat enlarges outward, and at its extremity on either side is provided with vertical grooves, the more readily to admit of connecting it with the flume. A wheel of this size will weigh from 2000 to 2500 lbs., and can be put up, all expense included, for about \$150. Nearly all the wheels in use are made of wood, in the following manner, viz.: a course of 2 $\frac{1}{2}$  or 3 inch plank is laid level in the bed timbers; the rim, or circumference, is formed of timber framed together at the corners, and curved out so as to form the proper inside shape. The top

is to be formed also of plank jointed together, and the whole well secured together; an opening must be left through the top, to admit the shaft to turn freely, without rubbing.

The periphery of the wheel case varies as much from a true circle as is equal to the breadth of the throat. A convenient mechanical method of generating this spiral curve is as follows: when the breadth of the throat is determined on, prepare a circular piece of wood, whose circumference is equal to the breadth of the throat; plant this circle exactly in the centre of the shaft; then fasten a small wire to the side of the circle opposite the throat, and in a loop prepared for the purpose, put the point of the scribe, and proceed to trace the curve; when an entire revolution is made, the wire will be wound once around the circular plane in the centre, and of course the radius will be shortened just the breadth of the throat. This is a convenient and true method of generating the required spiral curve.

In conclusion, it may be remarked that this wheel is entirely new; in form it is very simple, small in bulk, having no friction except on the journal of the shaft, and the friction of the water in passing through the case. When the

head and fall is eight feet and upwards, no gearing is necessary to give the proper motion to millstones; and when the head of water is below eight feet, single gearing, quite small, is all that is necessary. This wheel runs nearer the motion of the water than any other; and from the known effects of its operation, it clearly proves that water, when acting by its impulsive force, if such force can be intercepted, as is the case in this wheel, yields its maximum effect, equal gravity.

Having thus, sir, at some length, given a description of this new wheel, and the mode in which it may be constructed, should you deem it worthy, you are at liberty to give it a place in your valuable journal. The right to use this invention in all the States and Territories, except Delaware, New-Jersey, New-York, and the Eastern States, is not disposed of. Persons wishing to purchase the right for a State, County, Town, River, or a single dam, will be met on liberal terms by addressing me, post-paid, at this place. The wheel must, in all cases, be properly portioned to the head and fall in any given case, and the power required.

Yours respectfully,

JOHN MARTINEAU.

[From the Mechanics' Magazine.]

#### Description of Scripture's Power-Press.

On the platform, A, stand six posts, four long, B B B B, and two short, C C. Between the latter is suspended the windlass, D, upon a horizontal shaft, to which is attached one end of the rope, E, which passes in an inclined direction over a sheave in the upper end of an elevated post, F, the foot of which is secured by bolts, or staples, upon one of the long posts, from which sheave the said rope is

returned several times around the shaft of the windlass, D, and is fastened to the outer end of the acting lever, G, the opposite end of which lever is connected by means of an elliptical lever, H, to the power beam, J, which, by the operation of the windlass, D, forces down the moving fulcrum and follower, K and L, upon the material to be acted upon, M.

When this press is arranged for light pressure, as in the pressing of cheese, &c., a weight suspended upon the end of

the acting lever, G, is used instead of the windlass power, as above described.

The proposed advantages of this press, whether employed in heavy or light pressure, is derived from its powerful compound leverage, uniting economy in construction, with facility and simplicity of operation.

This press is well adapted, by a proper variation of its size, to the various purposes of letter pressing, seal and metal stamping; cotton, tobacco, cheese, &c.; for all of which it is manufactured and for sale by FRANCIS S. LAMB; 279 Bleecker, corner of Barrow street, New York.

**N. Y. AND ERIE RAILROAD.**—We publish to-day the proceedings of a public meeting, at Owego, in reference to the rejection, by the Legislature, of the application of the N. Y. and Erie Railroad for aid in constructing that work.

It is not surprising that, in the portion of the State whence these proceedings come, there should be such a feeling of resentment against the Legislature, for refusing the assistance which they might, with such perfect safety, have afforded to this enterprise; and which, timely given, would insure its prompt accomplishment.

The Company having it in charge, are indeed earnest in pushing on the work, but they cannot, from private subscription, hope to obtain at once so large a sum as will be requisite, nor feel justified in advancing with as much rapidity, as if the State had agreed to countenance the undertaking. Hence, there must be inevitably more delay than otherwise would have occurred—and in delay—there is in this, as in every other urgent case—danger.

Pennsylvania, however sluggish she may sometimes be deemed as a Commonwealth, is abundantly awake to the natural advantages of her position, and bold and persevering in the adoption of every plan, for improving still further those advantages.

In addition to the direct line of communication, now and for some weeks past, in such successful operation between Philadelphia and Pittsburgh, a new enterprise is about to be undertaken, which will become a direct rival as it were, for the trade of the West, with the Erie Rail Road. It is that connecting, through the waters of the Beaver river and the Mahoning, through the Mahoning valley, Pittsburgh, with the Ohio Canal at Akron—by means of a canal through Trumbull and Portage counties, Ohio. A road, into the heart of that great State is thus opened—direct—avoiding the circuitousness of the Ohio river, and striking the Ohio canal at a point so near Cleveland, as to make it possibly the earliest and easiest route, through that port, to convey merchandise to Michigan, and to the upper parts of Indiana and Illinois.

This work is thus recommended by the Board of Trade of Philadelphia, to the citizens of Pennsylvania.

The Directors of the Board of Trade, observe with great satisfaction that Books are to be opened in this city, on the 27th instant, for subscriptions to the capital stock of the Pennsylvania and Ohio Canal Company, under the very liberal Charter granted by the two States for the purpose of connecting the great Canals of Ohio and Pennsylvania, by a canal along the valley of the Mahoning to intersect the Ohio canal, at or near Akron—a work which has engaged the attention of the Board of Trade since its organization, and which on several occasions they have urged upon the attention of our Legislature and citizens, as an improvement of vital importance to the State and City. And now that the construction of this valuable improvement is placed within our power, the Board would again press

its claims upon the attention of the commercial and landed interest of our city, and upon all who desire to secure to Pennsylvania and Philadelphia the trade of Ohio, the Upper Lakes, and the Illinois and Indiana Canals, which lead to these Lakes. Therefore,

Resolved, That the Directors of the Board of Trade continue to entertain undiminished confidence in the advantages of a connection with the Ohio Canal, by the route of the Mahoning Valley, and of the important benefits which must result to the trade and commerce of our State and City.

Resolved, That this Board recommend to their fellow citizens, to secure the speedy construction of the said Canal, by promptly filling up the stock on the opening of the books.

Thos. P. CORN, President.

J. M. WRIGHT, Sec'y.

The stock, we need not add, was at once taken up—the work will proceed rapidly—and while the sordid calculations of political and personal interests, are permitted to paralyze the public energies, and to trifle with the highest interests, of this great State, Pennsylvania and Maryland are marching with giant strides, to take possession of those avenues of commerce with the West, which, when once formed, it is always most difficult, and frequently impossible, afterwards to change.

#### Railroad Meeting.

At a meeting of the citizens of Owego and other towns in the county of Tioga, held at the court house, on Friday evening, 10th inst., for the purpose of expressing their sentiments in relation to the recent rejection, by the Assembly, of the bill for aiding the construction of the New York and Erie Railroad—Hon. S. B. Leonard, was called to the chair, and George J. Pumpelly, appointed Secretary.

After a few very spirited and appropriate remarks by the chairman, as also by several other gentlemen present, a committee consisting of L. A. Burrows, T. Farrington, S. B. Leonard, James Pumpelly and Henry McCormick, Esquires, were appointed to draft resolutions expressive of the sense of the meeting.

The committee having retired for a short time, reported the following, which were unanimously adopted:

Resolved, That we consider the New York and Erie Railroad an object of the first importance to the State, and that its speedy construction is dictated by the soundest policy.

Resolved, That we entertain a high regard for the ability and experience of Judge Wright, as an Engineer, and that we believe his recent report to the Legislature, relative to the survey of the route for the contemplated Rail Road from New York to Lake Erie, to be entitled to the fullest credit.

Resolved, That in view of the great benefits that would necessarily flow to the State, when this grand work shall have been consummated, and especially to that portion of it through which the road is to pass,—in view of the strong claim which the southern tier of counties have for a participation in that system of internal improvement for which the bounty of the State has been so liberally extended to other sections of its territory,—and in view, also, of the fact, that an enterprising and responsible Company, chartered for the purpose, have proposed to enter immediately upon the construction of the work, and prosecute it to completion, on condition that the State would lend its aid, by authorizing a loan to the amount of one third of the stock, for which loan the company offered to furnish the most abundant security,—and from the fact, that this proposition, thus honorable as regards the Company, and safe, as respects the interests of the State, has been contumeliously rejected by one branch of our Legislature—we are reluctantly compelled to believe that there exists a settled determination to withhold from those privileges to which we are legitimately entitled, with the view of advancing the interests of our more favored neighbors at the north. Under all these circumstances, we feel called upon, as citizens of the Southern tier of counties, to express our full, unequivocal, and unqualified disapprobation of the course which has been pursued by the present Legislature, and we do not hesitate to pro-

nounce the policy by which they appear to have been governed in this matter, as unjust and oppressive,—and one which, if persisted in, cannot but be productive of the most pernicious consequences. The claims of the Southern section of the State, have been repeatedly and respectfully submitted, for a number of years in succession, by prayers and petitions, and as often have they been turned off with cold neglect. Forbearance, under such circumstances, cannot longer be considered a virtue. We have RIGHTS in this matter, and we owe to ourselves and to our posterity, independently to assert, and, if possible, maintain them. If sectional interests and influences are thus to be arrayed against us, and our equitable claims forever to be disregarded, we shall be compelled to act on the defensive, and waiving all other considerations, have recourse to our own sectional views and interests.

Resolved, That the acknowledgments of this meeting are due to the liberal minded and enterprising directors of the New York and Erie Railroad Company, for the determination manifested by them immediately to commence this great and important work, notwithstanding the refusal of legislative aid for the purpose.

Resolved, That we pledge ourselves to the Directors of the New York and Erie Railroad Company, to sustain them in this spirited and patriotic effort to the best of our ability.

Resolved, That disregarding all minor and party considerations, we will unite with our brethren of the other counties in this sequestered region of the State—in a vigorous and continued effort to assert those rights which have been disregarded and trampled upon, and that we will support no man for office, executive, or legislative, who is not known to be in favor of the New York and Erie Railroad, and who will not exert his utmost effort for the accomplishment of this great and important improvement.

Resolved, That we hereby respectfully request the Members of the Assembly from this county, and the Members of the Senate from this Senate District, to oppose all appropriation of public money for Internal Improvement, until justice shall be done to the southern tier of counties.

Resolved, That we are unwilling to submit our rights, either political or pecuniary, to the control of an Albany interest—and that when the stockholders and stockjobbers of that city, can bring themselves to bear thus effectively upon the legislation of the State—it is high time the Capitol was removed to some other location.

Resolved, That the thanks of this meeting are due to those members of the Assembly, who by their votes, and by their efforts on the floor of the House, sustained the bill for aiding the New York and Erie Railroad Company.

Resolved, That the thanks of this meeting are also due to those conductors of the newspaper press, who have so ably and faithfully sustained the interests of the southern tier of counties.

Resolved, That with a view to that concert of action which is necessary to the efficiency of our future efforts, it is expedient that a General CONVENTION be held at some central point, in the course of the next summer.

Resolved, That we respectfully recommend to our fellow citizens of the southern tier of counties, to appoint delegates to meet in convention at the Court House in the village of Owego, on Wednesday, the 29th day of July next; and that our fellow citizens of the adjacent counties, and all others interested in the construction of the New York and Erie Railroad, be invited to send delegates to said convention.

Resolved, That this meeting recommend to the people of the several towns in the county of Tioga, that a county convention be held at this place, on the 2d Tuesday in June next, for the purpose of appointing delegates to attend the general convention.

Resolved, That for the above purposes, Jedediah Fay, Ezra S. Sweet, and Harmon Pumpelly, Esqs. be a corresponding committee.

Resolved, That the proceedings of this meeting be signed by the officers thereof and published in the "Owego Gazette" and the other papers of the southern tier of counties; and that the editors of all other papers in the State friendly to the object, be respectfully requested to publish the same.

S. B. LEONARD, Chairman.

G. J. PUMPELLY, Secretary.

**Pennsylvania Canals and Railroads.**—A friend called at our office yesterday, and stated that he had just met a Western Merchant who had the day before returned from Tennessee, after having received, by way of the Pennsylvania Canals and Railroads, a stock of goods that he had purchased in Philadelphia this Spring. In conversation with the gentleman who communicated this statement, the Tennessean mentioned that a neighbor who travelled with him from the West during his first trip, and who preferred making his purchases in New York, was still in that city waiting for an opportunity to forward his goods by the canals of that state. No wonder our neighbors are anxious for the completion of the Erie Railroad. Goods to the the amount of thousands have been passing westward by way of the Pennsylvania improvements, for more than a month past, and yet the Erie canal has but just been filled with water.

The Argus will doubtless think it very questionable policy in us to republish such a paragraph as that above, from the Philadelphia Inquirer—but we feel nevertheless that it is both right and useful to do so. Until this State, and particularly this city, is made sensible of the enormous advantages which year after year Pennsylvania will derive from her earlier communication with the West by her Railroads and canals, than can be had by us, through the Erie Canal, there will not be aroused here that spirit, which alone is wanting, by making the accomplishment of the Erie and New York Railroad a certainty, to secure to New York very much of what Pennsylvania now monopolizes.

We have recently had occasion to see for ourselves, part of the prodigious benefits which the line of internal improvements from Philadelphia to Pittsburgh, is working to both cities, and to every intermediate point on the way. The point at which the railroad commences in Philadelphia—where within a recent period all was dullness—is now alive with the most hurried movements of an immense trade. Ranges of brick stores of the largest dimensions, built and building, line the street on each side for a great length, burdened care innumerable through the way—and all that steam and animal power can do, seems insufficient to satisfy the demands that are making for transportation both to and from this line.

Philadelphia itself has not known for many years such a trade as she is now carrying on, in sales of merchandise to the West. Merchants in numbers such as she has not before seen, are flocking thither from the valley of the Mississippi to make their purchases—very many of whom would come here in preference, if they could get their goods as early to market. But even though they should buy here and expedite their purchases to Philadelphia—as in twenty-four hours by the means of the Camden and Amboy Road, or Raritan Canal, they can do—they have not the same certainty of having their goods forwarded from Philadelphia, as if they were purchased in that city. This fact was stated in our hearing by merchants from the West—and it is not unnatural that it should be so. It is not pretended that goods bought in New York are always, or even systematically thus held back, but that when there is great pressure and great struggle for preference, the Philadelphia bought goods will have the precedence.

We do not belong to that school of economists which assumes, that the prosperity of one city is incompatible with, or adverse to, that of others—and it is not that spirit of envy, or hostility to, the growing greatness of Philadelphia and of Pennsylvania, by reason of her line of canals and railroads, that we desire so earnestly to impress the fact of this prosperity upon our readers. Our motive is to stimulate our own State and people to exertion—there is field enough for both. But if we are su-

pine, Pennsylvania will have by far the largest portion of the field.

If the owners of real estate, and the active merchants of this city, would only go and see for themselves the effect, in Pennsylvania, at this early part of the season, of a ready communication with the Ohio, we venture to say, the stock of the New York and Erie Railroad, the only expedient by which we can share in these benefits, would not remain unfilled another day.

[From the Baltimore American.]

As the recent Act of Pennsylvania, authorizing the extension of the State Canal from Columbia to the Chesapeake Bay, has placed our city in a new and most commanding position in reference to the whole line of Internal improvements of that State, we have thought that a brief notice of the extent and location of those improvements would not be unacceptable to our readers. In their Annual Report to the Legislature, presented in January last, the Canal Commissioners of Pennsylvania say to their fellow citizens:—"The six hundred miles of Canal and one hundred and twenty miles of Railroad which you directed us to have constructed, are now ready for use." Seven hundred and twenty miles is then the length of the State internal improvements, to which are to be added improvements by private companies, making the entire facilities of transportation by means of Canals and Railroads in the State of Pennsylvania amount in extent to upwards of a thousand miles. We propose rapidly to trace the course of the greater part of this great system, the Main Line of which commences in Philadelphia and ends in Pittsburgh.

The Columbia Railroad commences at two points on the Delaware river, the one near the Navy Yard in the southern extremity of Philadelphia, the other in the northern, in what is called the Northern Liberties. The routes from these two points join in the north western part of Philadelphia, and thence the road crosses the Schuylkill by a viaduct of one thousand and eight feet in length, and runs to Columbia, on the Susquehanna river, by a route of eighty-two miles. At Columbia commences the main line of the Pennsylvania Canal, running up the Susquehanna to the mouth of the Juniata, and thence along the Juniata to Hollidaysburg, a distance of one hundred and seventy-two miles. From Hollidaysburg the course westward is continued over the mountains by the Portage Railroad for thirty-six miles to Johnstown, where the canal navigation is resumed and continued to Pittsburgh, the length of the canal from Johnstown to Pittsburgh being one hundred and four miles. By this route the whole distance from Philadelphia to Pittsburgh is three hundred and ninety-four miles. By the Schuylkill and Union Canals—private works—the latter of which strikes the Pennsylvania Canal at Middletown, seventeen miles above Columbia, the distance is about four hundred and forty miles.

At the junction of the Juniata with the Susquehanna, which takes place about forty-three miles above Columbia, while the main line of the canal ascends along the banks of the Juniata, the northern line continues up the Susquehanna to Northumberland, a distance of about thirty-five miles. There it divides into two branches, one up the North Branch extending a distance of seventy miles to the mouth of the Lackawanna, ten miles above Wilkesbarre, and the other up the West Branch by a circuitous route of about the same distance to Dunstown. These two branches lead into regions that are rapidly improving. That on the North Branch abounds in anthracite coal, and that on the West Branch is bituminous.

By a reference to the map, the reader will perceive that all the improvements north and west of Columbia, the starting point of the Pennsylvania Canal, will be opened to Baltimore by the construction of the canal from that point down to the Maryland line, a distance of only 23 to 30 miles. From the Maryland line to Port Deposit a canal has long existed.

The Locomotive Engine, ordered for the Paterson and Hudson River Railroad, has arrived at this port from Liverpool and will be placed on the rail in a few days.

**First Boat at Buffalo.**—Extract from a letter dated at Buffalo, 29d April 8 o'clock, A. M.:—"The Troy and Erie Line Boat Nile, from Troy, has just arrived with a full cargo of merchandise destined for Ohio, Michigan and Illinois. No other boat has yet arrived from Albany or Troy."

The boats White Pigeon and Nile were the first boats arrived at Rochester which was the 20th inst., both belonging to the Troy and Erie Line.

**Lake Open—First Arrival.**—On Saturday evening last, the steamboat Wm. Penn, Capt. Dwight, arrived at this port from Detroit. This is the first arrival at the port of Dunkirk this season. The Wm. Penn, we understand, has been fitted up in a neat and handsome style, and has undergone several essential alterations, by which her speed and ability to encounter the frequent rough seas of the Lake has been much increased. [Dunkirk Whig of April 31.]

The Dunkirk Whig of 21st April, says that owing to the late strong winds blowing down the lake for several days past, the ice, which previous to the 21st inst. extended near 50 miles above this place, has been driven down about 10 miles below us, and lies packed up in one solid mass between that and Buffalo, so that it is believed that a navigable communication from Dunkirk to Buffalo will not be opened short of from three to five weeks. Should this be the fact, a vast amount of western produce will find its transit through the Welland canal, giving to the Canadas all the advantages of a trade which of right belongs to the State of New York.

In connexion with this subject, in relation to an earlier communication between the Lakes and the City of New York, we make use of the following language of the Rochester Democrat:—"New York may, if she will, enjoy almost exclusively and forever, the trade of the immeasurable west."

"The New York and Erie Railroad would for the present, secure all that is now secured by the Erie Canal. But this means is, for the present, perhaps for years, put aside. In thrusting it away, the State has struck a suicidal blow at its own prosperity and greatness."

The Burlington Free Press of the 24th, says: "Our steamboats are now all in motion. The Franklin and Phoenix commenced their regular trips yesterday, and will run for the present the same as last season—leaving each end of the Lake at one o'clock, P. M., and meet here about nine."

The Pittsburgh Gazette of the 16th, says:—"Business was we believe never so brisk as at present. The Canal is in full and successful operation—steamboats crowded with passengers and with full cargoes, are arriving and departing daily. Our Manufactories have all as much work as they can do. As to our merchants and commission merchants, they are all literally oppressed with business, being usually kept at work from daylight to midnight. We must admit that they bear this pressure most patiently, for we have not heard a single complaint."

The amount of tolls received for transportation on the Pennsylvania Improvements during the week ending the 18th inst. was 20,514 dollars 19 cents—a much larger amount, says the Harrisburg Reporter, than was derived from the same source during the corresponding period of last year.

A meeting of the freeholders of Alexandria was held on the 21st inst. and a resolution passed directing the Common Council to subscribe fifty thousand dollars to the stock of the Alexandria Canal Company, and that for the payment of the interest on this sum a tax be levied on the real estate in the town.

## NEW-YORK AMERICAN.

APRIL 25—MAY 1, 1835.

## LITERARY NOTICES.

CONFESSIONS OF A POET, 2 vols. Philadelphia, CAREY, LEA & BLANCHARD; for sale here by G. & C. CARVILL.—We hardly know what to make of these handsomely printed volumes. They purport to be confessions, and they unfold a state of mind which is pitiable enough. The story, which is altogether in the dark vein, of disgust of life, of doubt, not to say disbelief, of the future, and of actual guilt, is yet wrought out with occasional power and skill.—There are notes too, some in French, some in English, and one or two in Latin, which are meant to explain, extenuate, or justify the sentiments expressed in the text—and which are misanthropic and unjust enough to human nature. We can conceive no good to be acquired, and not much interest to be experienced, in reading this record of libidinous excesses and sceptical ravings.

JOURNAL OF A RECENT VISIT TO THE PRINCIPAL VINEYARDS OF SPAIN AND FRANCE, &c. &c. by JAS. BUSBY, Esq. N. Y., C. G. FRANCIS. A treatise on wines from New South Wales, is certainly a curiosity in literature, as well as in the progress of civilization, of which wine drinking is in some degree an indication. Mr. Busby having found the climate of the Convict Colony of England, favorable to the grape, determined on visiting the vine districts of the same or merely same climate in Europe, and collecting from them specimens of the most approved vines, and learning the process of making the wine. This therefore is a practical book, and in that point of view of interest even here.

THE PENNY MAGAZINE; THE PENNY CYCLOPEDIA; N. Y., WM. JACKSON 53 Cedar st; These publications—cheap, accurate, and comprehensive, issued by the London Society—for the diffusion of useful knowledge, continue to be regularly published here in monthly numbers, at 12 1/2 cents each.

JAFRET IN SEARCH OF A FATHER—Franklin Library Edition—part 1. N. Y., WALLIS & NEWALL.—This admirable story by Capt. Marryatt is republishing in this library—in numbers which cost 12 1/2 cents each—as fast as it is received from England.

LIVES OF THE ENGLISH PIRATES, HIGHWAYMEN AND ROBBERS; by C. WHITEHEAD. 2 vols.—Philadelphia: E. L. Carey & A. Hart. For sale in New York by Wiley & Long.—The records of crime are always more attractive than those of virtue. We will not stop here to inquire, what principle of our nature it is which determines this preference, but appeal to the fact, that books, such as that now under notice, always find ready sale and willing readers. This compilation, beginning with Robin Hood, and ending with the pickpocket Barrington,—almost a contemporary of the men of this day,—developes a series of crimes, murders, thefts, and violence of all sort, that cannot but be very edifying to all inquirers after, or believers in, the perfectibility of human nature.

DISCOURSES ON VARIOUS SUBJECTS BY REV. ORVILLE DREW; 1 vol: N. Y. DAVID FELT.—“Cut off by ill health,” as the Rev'd author tells us, from his pastoral connexion with a people with whom, during a period of ten years he had been accustomed to meet in the service of religion, he now publishes the sermons preached during that time, as a record of the interest taken by him in his congregation. The volume is dedicated to “the first church and congregation in

New Bedford,” and it is most to be received by them, to judge from portions of the work we have looked at, with affection and respect.

SKETCHES OF SOCIETY IN GREAT BRITAIN AND IRELAND; by C. S. STEWART. 2 vols. Carey Lea & Blanchard.—This is a second edition, handsomely printed, of a work heretofore noticed by us. Its popularity may, we presume, be inferred from the fact, that it has thus early run to a second edition. We see no reason however, to alter our original opinion, that it is a light work, rather calculated for the eye of partial friendship, than for the ordeal of a calm and cold public.

We have received, and cheerfully publish, the following notice of some little works fraught with moral and religious instruction, which are published by a Society, and are to be had at 205 Broadway:

“ANN CONOVER” is the history of a young Irish girl, who, being deprived of her mother by death soon after her arrival in this city, was compelled to resort to domestic service for a support. In her attempts at procuring a situation, she was aided by an affectionate aunt, who was well qualified by long experience and true Christian principles, to instruct her niece in the duties of her station. Her counsels and directions are founded on the only true rule of duty, *the Bible*; and the whole is written in a style of great simplicity and clearness.

This work is well calculated to benefit the large class for whom it is specially designed; and, when we remember how much of our domestic happiness depends upon the proper discharge of the relative duties which devolve on servants and their employers, we cannot but recommend to every lady at the head of a family, first to read “Ann Conover” herself, gleanings many useful hints for her own guidance, and then to place it in the hands of her domestics.

“THE GOOD RESOLUTION;” a little book of 69 pages, containing an account of a young girl, who rendered herself uncomfortable, and caused much unhappiness to her parents, by the habit of indulging in a fretful and irritable temper.

On the morning of her fourteenth birthday, she was induced by the judicious instructions and entreaties of her kind mother to form a solemn resolution to try to subdue her perverse temper. In this resolution, she was enabled to persevere, and succeeded so well, that, before the year had closed, her improvement was hailed with delight by her family, and was the source of new happiness to herself. All little girls who indulge in similar bad habits, are invited to read this account of Isabella Gardner, and “do likewise.”

“THE REFUGEE;” or story of Archibald Thompson.—This is the narrative of a boy whose mother, anxious for her son's improvement, sent him to a good school six days in the week, and on Sundays, to a good Sunday School.

But, notwithstanding his mother's kindness, and his teachers' faithfulness, he yielded to the influence of evil association, and the power of temptation, until, he was at length, guilty of a crime for which he was summoned before a magistrate, and sent to the House of Refuge. The book commences with an allusion to the *Cities of Refuge*, as once existing in the land of Judea; and then states more particularly the design of a House of Refuge, and its first introduction into the city of New York, and the subsequent erection of a similar building in Philadelphia. Of the arrangements of this latter institution, a minute and

interesting account is given. To Archibald Thompson was sent, as a place of correction and instruction. This history is continued in another little volume lying before us, called,

“THE INFIDEL'S CLASS;” the design of which is stated to be, “to remove some of the common difficulties which young men find in the attempts they make to form religious habits, and to furnish them with such rules of conduct, as will enable them to escape from much of the evil that is in the world.” In the course of his instructions in the House of Refuge, the teacher was surprised to find *seventeen* of the older boys, who *entirely disbelieved the Bible!* He at once proposed to form a class to talk about the truth of the Bible, and to find out what evidences there might be to support it. The proposal was acceded to, and in five distinct conversations with the boys, various proofs of the authenticity and inspiration of the scriptures are adduced and carefully examined, and objections answered so satisfactorily, that each one of the class separately declared his sincere and honest belief that *the Bible is true*. The book concludes with various directions to Archibald on the occasion of his leaving the Refuge, to live with a respectable farmer in the country.

These little books are elevated in their character, written in an easy perspicuous manner, and treat of subjects so important to all, that, not young readers merely, but those of more matured intellect, may read them with interest and profit. They are besides, presented in a very neat dress, and embellished with many appropriate engravings.”

MEMOIRS OF CELEBRATED WOMEN OF ALL COUNTRIES, by MADAME JUNOT, 2 vols.: Philadelphia, CAREY, LEA & BLANCHARD. For sale by G. & C. CARVILL, N. Y. These two volumes will certainly attract attention, for they present very striking pictures. Queens, murderers, women celebrated in letters, and in arms, figure alternately. The list however is far from complete. We give an extract from the life of *Charlotte Corday*, whom love of country, and the excitements of a revolutionary age, made a murderer:—

The day after she went to the Palais Royal and bought a sharp-pointed carving-knife, with a black sheath. On her return to the hotel in which she lodged—Hotel de la Providence, Rue des Augustins—she made her preparations for the deed she intended to commit next day.—Having put her papers in order, she placed a certificate of her baptism in a red pocket-book, in order to take it with her, and thus establish her identity. This she did because she had resolved to make no attempt to escape, and was therefore certain she should leave Marat's house for the Conciergerie, preparatory to her appearing before the revolutionary tribunal.

Next morning, the 14th, taking with her the knife she had purchased, and her red pocket-book, she proceeded to Marat's residence, No. 18, Rue de l'Ecole de Médecine. The representative was ill, and could not be seen, and Charlotte's entreaties for admission on the most urgent business were unavailing. She therefore withdrew, and wrote the following note, which she herself delivered to Marat's servants.

“CITIZEN REPRESENTATIVE, I have just arrived from Caen. Your well known patriotism leads me to presume that you will be glad to be made acquainted with what is passing in that part of the republic. I will call on you again in the course of the day; have the goodness to give orders that I may be admitted, and grant me a few minutes conversation. I have important secrets to reveal to you.”

“CHARLOTTE CORDAY.” At seven o'clock in the evening she returned, and reached Marat's antechamber; but the woman who waited upon him refused to admit her to the monster's presence. Marat, however, who was

in a bath in the next room, hearing the voice of a young girl, and little thinking she had come to deprive him of life, ordered that she should be shown in. Charlotte seated herself by the side of the bath. The conversation ran upon the disturbances in the department of Galvados, and Charlotte, fixing her eyes upon Marat's countenance as if to scrutinize his most secret thoughts, pronounced the names of several of the Girondist deputies.

"They shall soon be arrested," he cried with a howl of rage, "and executed the same day." He had scarcely uttered these words, when Charlotte's knife was buried in his bosom.

"Help!" he cried, "help! I am murdered."—He died immediately.

Charlotte might have escaped, but she had no such intention. She had undertaken what she conceived a meritorious action, and was resolved to stay and ascertain whether her aim had been sure. In a short time, the screams of Marat's servant brought a crowd of people into the room. Some of them beat and ill-used her, but the Members of the Section having arrived, she placed herself under their protection. They were all struck with her extraordinary beauty, as well as with the calm and lofty heroism that beamed from her countenance. Accustomed as they were to the shedding of human blood, they could not behold unmoved this beautiful girl, who had not yet reached her twenty-fifth year, standing before them with unblenched eye, but with modest dignity, awaiting their fiat of death for a deed which she imagined would save her country from destruction. At length Danton arrived, and treated her with the most debasing indignity, to which she only opposed silent contempt. She was then dragged into the street, placed in a coach, and Drouet was directed to conduct her to the Conciergerie. On her way thither, she was attacked by the infuriated multitude. Here for the first time she evinced symptoms of alarm. The possibility of being torn to pieces in the streets, and her mutilated limbs dragged through the kennel and made sport of by the infuriated rabble, had never before occurred to her imagination. The thought now struck her with dismay, and roused all her feelings of female delicacy. The firmness of Drouet, however, saved her, and she thanked him warmly.

"Not that I feared to die," she said; "but it was repugnant to my woman's nature to be torn to pieces before every body."

Whilst she was at the Conciergerie, a great many persons obtained leave to see her, and all felt the most enthusiastic admiration on beholding a young creature of surpassing loveliness, with endowments that did honor to her sex, and a loftiness of heroism to which few of the stronger sex have attained, who had deliberately executed that which no man in the country had resolution to attempt, though the whole nation wished it, and calmly given up her life for the public weal.

Charlotte's examination before the revolutionary tribunal is remarkable for the simplicity of her answers. I shall only mention one, which deserves to be handed down to posterity.

"Accused," said the President, "how happened it that thou couldst reach the heart at the very first blow? Hadst thou been practising beforehand?"

Charlotte cast an indescribable look at the questioner.

"Indignation had roused my heart," she replied, "and it showed me the way to his."

When the sentence of death was passed on her, and all her property declared forfeited to the state, she turned to her counsel, M. Chauveau Lagarde:

"I cannot, Sir, sufficiently thank you," she said, "for the noble and delicate manner in which you have defended me; and I will at once give you a proof of my gratitude. I have now nothing in the world, and I bequeath to you the few debts I have contracted in my prison. Pray discharge them for me."

When the executioner came to make preparations for her execution, she entreated him not to cut off her hair.

"It shall not be in your way," she said; and taking her shawl, she tied her thick and beautiful hair on the top of her head, so as not to impede the stroke of the axe.

In her last moments, she refused the assistance of a priest; and upon this is founded a charge of her being an infidel. But there is nothing to justify so foul a blot upon her memory. Charlotte Corday

had opened her mind, erroneously perhaps, to freedom of thought in religion as well as in politics. Deeply read in the philosophic writings of the day, she had formed her own notions of faith. She certainly rejected the communion of the Roman Church; and it may be asked whether the conduct of the hierarchy of France before the revolution was calculated to convince her that she was in error? But because she refused the aid of a man as a mediator between her and God, is it just to infer that she rejected her Creator? Certainly not. A mind like hers was incapable of existing without religion; and the very action she committed may justify the inference, that she anticipated the contemplation, from other than earthly realms, of the happiness of her rescued country.

As the cart in which she was seated proceeded towards the place of execution, a crowd of wretches in the street, ever ready to insult the unfortunate, and glut their eyes with the sight of blood, called out: "To the guillotine with her!"

"I am on my way thither," she mildly replied, turning towards them.

She was a striking figure as she sat in the cart. The extraordinary beauty of her features, and the mildness of her look, strangely contrasted with the murderer's red garment which she wore. She smiled at the spectators whenever she perceived marks of sympathy rather than of curiosity, and this smile gave a truly Raphaele expression to her countenance. Adam Lux, a deputy of Mayence, having met the cart, shortly after it left the Conciergerie, gazed with wonder at this beautiful apparition—for he had never before seen Charlotte—and a passion, as singular as it was deep, immediately took possession of his mind.

"Oh!" cried he, "this woman is surely greater than Brutus!"

Anxious once more to behold her, he ran at full speed towards the Palais Royal, which he reached before the cart arrived in front of it. Another look which he cast upon Charlotte Corday completely unsettled his reason. The world to him had suddenly become a void, and he resolved to quit it. Rushing like a madman to his own house, he wrote a letter to the revolutionary tribunal, in which he repeated the words he had already uttered at the sight of Charlotte Corday, and concluded by asking to be condemned to death, in order that he might join her in a better world. His request was granted, and he was executed soon after. Before he died, he begged the executioner to bind him with the very cords that had before encircled the delicate limbs of Charlotte upon the same scaffold, and his head fell as he was pronouncing her name.

Charlotte Corday, wholly absorbed by the solemnity of her last moments, had not perceived the effect she had produced upon Adam Lux, and died in ignorance of it. Having reached the foot of the guillotine, she ascended the platform with a firm step, but with the greatest modesty of demeanor. "Her countenance," says an eye witness, "evinced only the calmness of a soul at peace with itself."

The executioner having removed the handkerchief which covered her shoulders and bosom, her face and neck became suffused with a deep blush. Death had no terrors for her, but her innate feelings of modesty were deeply wounded at being thus exposed to public gaze. Her being fastened to the fatal plank seemed a relief to her, and she eagerly rushed to death as a refuge against this violation of female delicacy.

When her head fell, the executioner took it up and bestowed a buffet upon one of the cheeks. The eyes, which were already closed, again opened and cast a look of indignation upon the brute, as if consciousness had survived the separation of the head from the body. This fact, extraordinary as it may seem, has been avowed by thousands of eye witnesses; it has been accounted for in various ways, and and no one has ever questioned its truth.

#### SUMMARY.

EXTRAORDINARY BALLOON VOYAGE.—The Cincinnati Gazette of the 18th inst., furnishes the following statement by the *Frontier* Mr. Clayton, of by far the longest voyage on record, we believe, in a ship of the air. In January, 1785, Blanchard, and Dr. Jeffries, an American, crossed the channel from England to France in a balloon, a distance of not more than 23 miles. Here the distance gone over is more than 400 miles.

We happened to be in Cincinnati when Clayton

made his ascent on Wednesday, 18th inst., and though we have seen many such performances, never saw one better conducted, or undertaken with more sang-froid. The voyager stood on the top of his car, supporting himself by the hoop through which the ropes passed from the netting of the balloon to it, and waved his flag, as long as he was visible, with as much confidence as though he were on *terra firma*. He told every one that he had with him provisions and clothing, and meant to do something that had never been accomplished before. He has fulfilled his promise amply.

Clayton is an American—a mechanic, we believe, of Cincinnati—and both constructed his own balloon and superintended the preparation of the gas, and the filling of the balloon. It is, too, his first experiment.

#### Mr. Clayton's Account of his Aerial Excursion.

At 6 o'clock I took my departure from the Amphitheatre, which was pretty well filled with spectators, the beauty and fashion of the city, and ascended with celerity into the atmosphere, amidst the cheering sounds of music, and the acclamations of my friends. In a few moments I had a full view of Cincinnati, of Newport, and Covington, and of the thousands of spectators that surrounded the amphitheatre, and covered every point which afforded a favorable opportunity of seeing the ascension. I soon arrived at a sufficient altitude to give the spectators a good view of the descent of my parachute, containing a dog of about 20 pounds weight. The parachute, on being liberated from the car, descended with great velocity for a considerable distance before it spread open. When it opened its descent was more slow, and as I watched its course downwards, thought for some time it was falling in the Canal, but at last saw it pass a little on one side; and I have no doubt it arrived safe upon *Terra Firma*. As I ascended the scene became more extended and diversified, but every object more diminutive. The spectators shrank to Lilliputians, and the horses and carriages on the roads were like the toys of children. The hills around the city, which form the boundary of one's view when below, sank into the earth, and became on a level with the plain; and far beyond them, amidst the vast woods, I could distinguish numerous towns and cultivated spots. The whole appeared like an extensive map spread at my feet, with every street, and alley, and building, and every improvement plainly marked upon it. Through the centre the Ohio passed, and wound its serpentine course in each direction, until lost in the mist, which surrounded the scene, and for a number of miles I could trace the river Licking, the zig-zag course of the Miami Canal, and the turnpikes and different roads branching from the city. At starting the Barometer stood at 29.3.10 inches, and Thermometer at 72 degrees. The wind carried me east south east, in the direction of Batavia.

At a quarter past 5, the Barometer stood at 19 inches, and the Thermometer 26 degrees, I began to feel cold, and put on my great coat. At this time I heard the report of a Cannon, and could hear at this height the noise of the Woodman's axe. About this time I passed over the Little Miami River, kept the Ohio River a little to my right, and after descending a little I had a fine view of the towns and cultivated spots on each side of me.

A little before six I passed over Batavia, and continued to travel in an East South East direction. My altitude at this time, as indicated by the Barometer, was 21-2 miles. I again felt a little cold; the Thermometer stood at 23 deg. I sat myself down in the car and took some refreshment. I was now moving delightfully through the air; the little agitation the balloon received on starting had now ceased, there was not the least rotary or oscillatory motion perceptible; not a ripple in the silk of the balloon to be seen, and all was perfect silence. I could have almost imagined that I was an inhabitant of a little world of my own, fixed in the immensity of space, and could view at my feet, the earth in motion, re-

volved on its axis. I felt no unpleasant sensation, no difficulty in breathing, no pain nor swelling in my head, as has been said by some Aeronauts, to be experienced at great altitudes; but I have no doubt, that at the altitude of 3 1-2 or 4 miles, owing to the rarity of the atmosphere, a difficulty in breathing, and a swelling in the head, is experienced.

At the altitude of 2 1-2 miles, the scenery is not so beautiful as it is when about half a mile from the earth; for the objects appear concealed in mist, and have a monotonous appearance. At 25 minutes after six, I had a fine view of the setting of the Sun; 30 minutes after six I passed over Williamsburg; about 7 o'clock over Georgetown; and although I was several miles distant from the Ohio river, it appeared but very little to the right of me, and I could distinctly see Augusta and Maysville, and the towns and farms alongside of the river. A little before 8 o'clock I passed over West Union. The wind now changed a little to the south, about one point, making S. E. by East. About 9 o'clock, I passed a little to the left of Portsmouth; could see plainly the Scioto River and the canal. I was enabled to see the different places over which I passed by the light of the Moon, and by the lamps and lights in the houses. These lights, which were numerous, and which I could see in every direction in which I turned my eye, formed a field of fiery stars at my feet, and contrasted finely with the brilliant stars that shone in the cloudless hemisphere above me.

A little beyond Portsmouth I had a fine view of the Iron Forges and Furnaces, whose fires illuminated the atmosphere for a number of miles. I could not by the light of the moon, make any Thermometrical observations, the quicksilver in the tube being so small I could not see its height; but the quicksilver in the Barometer being of greater volume, I could plainly see it move up and down; and although I could not see the figures on the scale,—yet, I could tell when I was at a safe distance from the earth, by the distance that the quicksilver stood above a piece of brass which formed a protection to the Thermometer, immediately alongside of the Barometer. Whenever I felt tired, I would seat myself in the bottom of the car, placing the Barometer opposite to me, watch its height, and when I found it rising, would throw out some ballast and counteract its course. Now and then I would look over the car, and notice, particularly, the direction and situation of the water courses which I had in sight, nearly the whole of my voyage, and without which I should not have been able to trace my course. Soon after passing the Scioto River, I entered another current of air, which carried me due East, and immediately over Concord. Soon after I passed into another current, which carried me East North East, and brought me at 11 o'clock, nearly up to Gallipolis, a little below which I crossed the Ohio River. On passing into a new current of air, the Balloon is slightly agitated, at which time I would always be particular in ascertaining its direction. Soon after crossing the O., the Balloon was again agitated, and I found that I had passed from the East North East current, into another, which carried me South East, and soon brought me over the Kanawha River, and from the rapidity the terrestrial objects appeared to move, I found my rate of travelling had increased. At half after 12 I passed over Charleston, and in a few minutes I was carried over the Furnaces of the Kanawha Salt works. I continued this course until I was in sight of the fork formed by Gauley and New rivers.

While in sight of New River I approached the earth: my ballast was nearly exhausted, and as the place over which I was floating appeared to be an open country, I prepared for a descent. I threw overboard my Anchor, which, after dragging for a little distance, caught firmly hold of a tree; but on coming close to the top I found, to my surprise, that instead of a fine open country, I was in a dense forest, on a considerable elevation. The wind was blowing powerfully, and finding it impossible to break the hold of the anchor, the only way of liberating myself from this situation was to cut away the cable. This I did, and in a short time ascended to an altitude as great as I had previously attained. The cold was intense, but I could not ascertain the height of the Thermometer: I have no doubt it was nearly as low as zero. I had now lost sight of the water courses, and could see no lights in any direction. I had myself down in the bottom of the Car, buttoned my coat tightly around me, put on my gloves, covered myself with

two blankets, which I had taken as wrappers for the Balloon, drank some brandy, felt comfortable and highly delighted with my novel trip, and in this situation fell fast asleep. I was awakened, at last, by my Car striking. I immediately sprang on my feet, and in another moment the Car was dragging over the tops of the trees. I saw before me a river and I thought some buildings; they appeared but a little distance from me; but I afterwards found they were about four miles off.

I attempted to stop my Balloon by clinging to the branches of the trees. Several of them broke; but at last I caught hold of a strong bough, and by clinging with all my strength with one hand, and pulling the Valve-rope with the other, I was enabled in a short time to draw my Car down the tree several feet, and to secure it by means of a rope. After being confident that I had secured my balloon, I looked at my watch and found it to be half after 2 o'clock. At this time of the morning I thought it would be useless to go in search of any assistance. I therefore remained in the Car, 40 feet at least from the ground, until day-break, and then descended to explore the wilderness in which I had landed.

I could discover no trace of human footsteps, no mark of change produced by man. Numerous large trees had been levelled to the ground, but there was no mark of the woodman's axe upon them; they had evidently been uprooted by the hurricane. Perceiving that I was on a mountain and that there was another point still higher, I ascended to the top of it and could perceive in the valley, and in the direction that I had seen the river the previous evening, a cultivated spot. After travelling alongside of a beautiful spring rivulet for about 3 miles, I found this spot, and had to follow a track of 2 miles further to get assistance. We conveyed the balloon to the house of Mr. Joseph Graham, a respectable and intelligent farmer with whom I remained 3 days before I could get a conveyance to return. During my stay at Mr. Graham's I was visited by great numbers of people from the surrounding country.

The spot on which I landed, is the top of the mountain, 3000 ft. (as indicated by the Barometer) above the level of the sea, and is called Stevenson's Knob, or Stinson's Knob, near Keeney's Knob, Monroe county, Virginia, about four miles from Green Brier River, 18 miles from Union, 20 miles from Louisville. I travelled in the Balloon, of three hundred and fifty miles, but according to the usual method of travelling, more than 400 miles, which distance I travelled in 9 1-2 hours.

This voyage I believe has fulfilled the promise made in my advertisement, and is the longest voyage, by far, ever performed by any person in a Balloon.

**EXTRAORDINARY PERFORMANCE.**—The purse of \$1000 offered by Mr. J. C. Stevens to any one who should succeed in going ten miles, on foot, within the hour, was yesterday gained, eleven seconds within the time, over the Union Course, L. L., by a Connecticut man, named Henry Stannard, a farmer of Killingworth. Two others, as we learn from the Courier, went the 10 miles, one a Prussian, named George W. Glaeur, who did the distance in 60 1-2 minutes—and the other an Irishman named Mahoney, who did it in 61 3-4 minutes.

There were at starting nine competitors, whose names and deeds are thus set forth in the Courier:

	MILES.									
	1st	2d	3d	4th	5th	6th	7th	8th	9th	10th
Stannard,	3	4	3	3	3	2	2	1	1	1
Glaeur,	2	2	1	1	2	3	3	3	2	2
Mahoney,	1	1	5	5	4	4	4	4	2	2
Downes,	5	3	2	2	1	1	1	2	gave in.	
McGargy,	6	7	7	7	5 gave in.					
Wall,	4	5	4	4	4 gave in.					
Sutton,	8	8	6	6	gave in.					
Mallari,	9	9	8	8	fell and gave in.					
Vermillye,	7	6 gave in.								

The winner did not show much fatigue, and was seen soon after riding about the Course.

The other two who went the ten miles received \$200 each.

The Courier gives this statement of the time in which each mile was done by the winner:

	Min.	Sec.
1st. mile.	5	36
2d. "	5	45
3d. "	5	58
4th. "	6	29
5th. "	6	9
6th. "	6	3
7th. "	6	1
8th. "	6	3
9th. "	5	57
10th. "	5	54
	59	48

It is said that the course is six feet over a mile, making sixty feet more than the ten miles, in the distance run.

Now 60 feet being the 88th part of a mile, it would allow (taking the time of the last mile) four seconds, which is to be deducted, making the distance therefore in 59m. 44s.

The speed of the runners will be best estimated perhaps by stating, that Stannard was accompanied the whole distance by Mr. Stevens on horseback, and that the horse was all the time on a fast center.

A bill passed the Assembly to-day, by a vote of 89 to 8, subjecting non-resident lands to taxation, for the improvement of roads and bridges, to the same extent that the lands of residents are taxed in the several towns. The bill passed the Senate last week, and only requires the signature of the Governor to become a law. It will be an important law for the western part of the State.—[Albany Evening Journal.]

**New Publications**—from the press of Messrs. Cary Lea & Blanchard:—"Memoirs of Celebrated Women of all Countries," by Madame Junot—two duodecimos. The translation was made in London, and has been commended there. We doubt not that Madame Junot has acquitted herself well as far as she has proceeded in her interesting task, which will be continued without delay.

"The Juvenile Popular Library"—Boston—published by John Allen & Co. The first volume—a very neat one—of this series, is on *Domesticated Animals*, considered with reference to civilization and the arts. It is well adapted to the instruction and entertainment of youth.

"The American Popular Library"—Boston, duodecimo—conducted by an Association of Gentlemen. The present number is entitled *New England and her Institutions*, and contain some good sketches of New England life. But the eleventh chapter deserves strong reprehension. It consists of foul obloquy on the Irish Catholics, and seems to have been introduced as a seasoning for the book. False anecdotes of priests and Irishmen are told, with a strain of remark such as this—"An Irish Catholic is impervious to reason. It is in vain to argue with him. \* \* \* Look at a gang of fifty Irishmen, and you can select a Yankee, if there be one among them, almost as readily as you could if he were surrounded by so many negroes." Forbear Gentlemen!—[Gazette.]

**SEAT OF WAR IN THE NORTHWEST**—Commencement of Hostilities.—From the latest intelligence received and contained in the following letter in the Cleveland Whig, of April 22d, we regret to perceive that matters are assuming a more serious aspect than we had imagined:

MAUMEE, April 16, 1835.—"With regard to the war, I will say without entering into particulars, that I strongly suspect that blood will be shed here in less than ten days. May God avert it; but if the present rash course of Michigan is pursued, the sword and bayonet will have to determine the controversy. We are driven from our homes for acting under the authority of Ohio; our houses are broken open in the dead of night; citizens taken prisoners, bound hand and foot, and tied to wild fiery horses, gagged that they may not alarm the rest of the citizens; the females too in the same house are treated with violence by being held and prevented from going to alarm the neighbors; and all this for saying to an individual he need not obey the laws of Michi-

gas. After this first attack, 280 horsemen, armed with guns and bayonets, came into our place, took three individuals, two of whom they released. They were not able to take any of the officers, whom they designed to take, and were so overpowered that they fell at the Ohio flag, made out of cotton cloth, and tied it to a horse's tail, and dragged it through the streets and departed. The citizens soon raised another, and three days after they came with an armed force, and took an Irishman for whipping a negro after he had been dared to do it; and took an axe, cut down the tree that contained the flag, and bore it to Monroe as a trophy of their victory, and burnt it.—We can destroy this band of ruffians, and the Governor wishes us to forbear; and it is probably the best. He will probably be molested in remarking our northern line; and then we shall have an opportunity to settle the whole."

**THE ARMY.**—We learn from the Army and Navy Chronicle that General Roger Jones has resigned his commission, in the line of the Army, as Lieutenant Colonel of the Fourth Regiment of Artillery. He retains however, his Staff appointment as Adjutant-General of the Army.

The following List of Promotions, is from the Chronicle:

Major A. S. Brooks, of the 3d Artillery to be Lieutenant-Colonel of the 4th Artillery, vice Jones resigned.

Captain Sylvester Churchill, of the 1st Artillery, to be Major of the 3d Artillery, vice Brooks, promoted.

First Lieutenant Justin Dimick, of the 1st Artillery, to be Captain, vice Churchill, promoted.

Second Lieutenant Edmond French, of the 1st Artillery, to be 1st Lieutenant, vice Ramsey, appointed Captain of Ordnance.

Second Lieutenant, William Palmer, of the 1st Artillery, to be 1st Lieutenant, vice Dimick, promoted.

Brevet 3d Lieutenants T. A. Morris, and E. T. P. Allen, of the 1st Artillery, to be 3d Lieutenants, vice French and Palmer, promoted.

Gen. J. E. West, one of the inspectors General of the Army, is on a tour of inspection to some of the Northern military posts.

The Branch Bank of the United States at Washington has commenced the operation of winding up its concerns, preparatory to the expiration of the charter.

By the following notice from the Freedmen, it will be perceived that the Farmers' & Mechanic Bank of New Brunswick has resolved to withdraw from circulation all notes of the denomination of those stolen last winter:

TO THE PUBLIC.

The Farmers' & Mechanic Bank of New Brunswick, hereby give notice, that in consequence of the depreciation committed upon it in February last, it has withdrawn from circulation its first emission of notes of the denominations of 100 dollars and 50 dollars. None of them are now out, it is believed, but those that were stolen; and they will not, of course, be redeemed.

A new emission, is, however, to be made of those denominations. They will be filled up with red ink; dated on the 1st of May, 1835; made payable, the 100's to C. Dunham, and the 50's to P. Nefus; numbered from 200 upwards; and endorsed by Wm. P. Furman, Assistant Cashier.

By order, L. CARMAN, Cashier.

New Brunswick, April 12, 1835.

**Things at New Orleans.**—The Legislature of New Orleans have enacted that a poll tax of one dollar per head on every cabin passenger, and fifty cents on every deck and steerage passenger that shall arrive at that place by ships or steam boats, shall be collected. The proceeds are to be appropriated, one half to the Charity Hospital; the other half to be divided between the Orphan Asylum, male and female, and the primary schools of the city. A new mode of levying contributions this; it will become that annually, a Whig Legislature that elects a Jackson Senator in Congress. Two collectors are to be appointed

whose salaries shall not exceed \$3000 each!!! Such an enactment would produce a pretty sum to Cincinnati.—Quere, as to its policy, liberality or constitutionality?—[Cincinnati Gaz.]

The Estate of the late Mr. Samuel Slater, who died recently at his residence in Webster, Mass., is estimated at about Two *ARMIES* of Dollars! the result of a life devoted with singular perseverance and industry to the manufacturing business, into which he has introduced many valuable improvements.

The brig Fairy, Capt. Josiah Wing, arrived at Boston from Philadelphia, on Thursday morning, having made the trip from Boston to Philadelphia and back, in just fourteen days, with full cargoes both ways.

**Battle of Lexington.**—An interesting ceremony took place at Lexington, Mass., on Monday, April 30th, in commemoration of the events in 1775. "The concourse of people from that and the neighboring towns, and from Boston," says the Boston Gazette, "was very great. At eleven o'clock, a procession, escorted by two military companies in uniform, under the direction of General Chandler as chief marshal, aided by several assistant marshals, was formed in front of the "Monument House," and proceeded to the burying-ground. Here the remains of Monroe, Parker, Hadley, the two Harringtons, Muzzy, Brown and Porter, the men who fell a sacrifice to the cause of liberty and the country, on the morning of the memorable nineteenth, (which had previously been taken from the grave and placed in a sarcophagus) were received into the procession, drawn on a hearse by a white horse; and the whole proceeded to the Meeting house. The sarcophagus was placed in the aisle fronting the pulpit, the two military companies standing in the aisle." The services of the occasion were as follows: Durga by the choir; prayer by Rev. Mr. Walker, of Charlestown; Ode,—written by Mr. Pierpont of Boston; Oration by the Hon. Edward Everett; Ode,—written by Miss H. P. Gould. At the close of these services, the procession was again formed, and the Remains were taken to the Monument, where a new tomb had been prepared for their reception. Having completed this interesting ceremony, the procession returned to the "Monument House," in the rear of which, and under a spacious pavilion, a collation had been provided.

**Death of Dr. Nutt.**—In copying our late contradiction of the decease of Dr. Nutt of this State, in Candia, in Egypt, to Cairo, the Landmark adds the following

formed by an American gentleman from Egypt, with whom we the traveller alluded to is not York, but Dr. Nutt of Natchez, Nutt, accompanied by his son, is in the latter part of September proceeded up the Nile, geological reconnoissances of the Nile, so far as the second cataracts. He then purposed to cross the desert, to Mount Sinai, and thence passing through Palestine and Syria, to return to Paris, via Constantinople and Vienna.

There were three Americans in Alexandria when Dr. Nutt arrived, and by them he was supposed to be Dr. Nutt. They were all delighted with the arrival of their distinguished countryman, and they immediately said he must be introduced to the Pacha, and talk about his inventions. But unfortunately Egypt required no steam, and possessed no *infrastructure*: at all events there should be a Yankee improvement upon the oven for *hatching* *attorneys*. Nutt was, however, soon found to be Nutt, and with this discovery disappeared the Yankee projects of improving Egypt. Some *slavagery* *and* *quackery* *and* *northern*, and a *Piedmontese* *hulk* of Cairo to our informant, *was* *not* *at* *all* *contemptible*. Very true, he replied, we are always improving.

We may mention some names of American travellers who were in Egypt last year: Mr. Lard, of South Carolina; Stackpole, of Boston; Cohen, of Baltimore; Hammondeley, of New-York; Muyo, of North Carolina. Mr. Lowell, of Boston, accompanied by a *nut*, which distinguished him for taste and opulence, was travelling in Turkey. He was expected in Egypt, and it was said that he designed to visit India by way of the Red Sea,

The brig Haleyon, which arrived at Boston from Trieste, reports that she passed Gibraltar on the 14th ultimo, in company with an American Frigate, bound to this country, having on board a large number of expatriated Poles.

The following gentlemen were yesterday elected Trustees of the New York Society Library for the ensuing year:—John J. Morgan, Edward W. Lought, David S. Jones, Gulian C. Verplank, J. Kearny Rodgers, Everett A. Bancker, John Le Conte, James Campbell, Rev. William Berrian, John Anthon, Henry I. Anderson, Washington Irving. [\*Newly elected.]

**STATE LANDS AT AUCTION.**—The Saragosa General has given notice, that all the un sold State Lands situated in Buffalo will be sold at Auction—the sale to commence on Monday the 22d day of June next. One-fourth of the purchase money to be paid at the time of sale, and the remainder in six equal annual instalments, with interest at six per cent.

The packet ship Charlemagne sailed Friday, for Havre, seventy-three days from the date of her previous departure for the same port. Within that space, she has had on board three full cargoes, and landed two of them on opposite sides of the Atlantic.

**Cotton.**—The Columbia Telescope of the 19th inst. says: "A choice lot of 90 bales of Cotton, from the plantation of Dr. Herndon, of Union, was sold yesterday by the Hon. Wm. Rice, to Mr. Felix Meetez, for 18 7-8 cents—the highest price that has been given in our market this season. Good to fair ready commands from 17 to 17 1-2."

**POPULAR EDUCATION.**—We consider the annexed act, lately passed by our Legislature, as laying the foundation—if it be duly appreciated and fully carried out, by the inhabitants of the School districts—of a most essential and much needed improvement in our Common School Education.

The smallness comparatively of the sum, must not lead any one to suppose, that the consequences will be in proportion. Far, very far from it. A few books well selected, may inoculate—no one can say how many, minds, and decide their bias forever. The District Library will be the foundation, or we mistake the matter much, of a new and higher order of district instructors; for the master who has scholars that can read, will not be able long to hold his place, if he do not too, both read and think.

We trust the country papers generally will exert themselves to make this law universally known, and to point out the certain and unalloyed benefits, which the establishment of libraries such as it contemplates, must confer upon every district where they are introduced.

An act relating to Public Instruction. Passed April 12, 1835.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

§ 1. The taxable inhabitants of each School District in the State, shall have power, when lawfully assembled at any district meeting, to lay a tax on the district, not exceeding twenty dollars for the first year, for the purchase of a district Library; consisting of such books as they shall, in their district meetings, direct, and such further sum as they may deem necessary for the purchase of a book case. The intention to propose such a tax shall be stated in the notice required to be given for such meeting.

§ 2. The taxable inhabitants of each school district shall also have power, when so assembled in any subsequent year, to lay a tax, not exceeding ten dollars in any one year, for the purpose of making additions to the District Library.

§ 3. The clerk of the District, or such other person as the taxable inhabitants may, at their annual meeting, designate and appoint by a majority of votes, shall be the Librarian of the District; and shall have the care and custody of the Library; under such regulations as the inhabitants may adopt for his government.

§ 4. The taxes authorized by this act to be raised, shall be assessed and collected in the same manner as a tax for building a school house.

*Progress of the ancient Egyptians in the Fine and the Useful Arts.*—On the right hand wall are some very elegant vases, of what has been called the Greek style, but common on the oldest tombs in Thebes. They are ornamented as usual with *Arabesques* and other devices. Indeed, all these forms of vases, the *Tuscan* border and the greater part of the painted ornaments which exist on Greek remains, are found on Egyptian monuments of the earliest epoch, even before the Exodus of the Israelites; which plainly removes all doubt as to their original invention. Above these are carriages, chariot-makers, and other artisans. The semi-circular knife used for cutting leather is precisely similar to that employed in Europe at the present day for the same purpose, of which there are several instances in other parts of Thebes; and another point is here satisfactorily established, that the Egyptian chariots were of wood, and not of bronze, as some have imagined. —[Wilkinson's General View of Egypt.]

*Literary Confession.*—A French author I was reading last night says, he that has written will write again. If the critics do not set their foot upon this first egg that I have laid and crush it, I shall probably verify his observations; and, when I feel my spirits rise, and that I am armed with industry sufficient for the purpose, undertake the production of another volume. At present, however, I do not feel myself so disposed; and, indeed, he that would write should read; not that he may retail the observations of other men, but that, being thus refreshed and replenished, he may find himself in a condition to make and to produce his own. I reckon it among my principal advantages, as a composer of verses, that I have not read an English poet these thirteen years, and but one these twenty years. Imitation, even of the best models, is my aversion; it is servile and mechanical, a trick that has enabled many to usurp the name of author, who could not have written at all, if they had not written upon the pattern of somebody indeed original. But when the ear and the taste have been much accustomed to the manner of others, it is almost impossible to avoid it; and we imitate, in spite of ourselves, just in proportion as we admire. —[Cowper the Poet's Letters.]

*Plagues during the Middle Ages.*—Every country in Europe, and Italy perhaps more than any other, was visited during the middle ages by frightful plagues, which followed each other in such quick succession that they gave the exhausted people scarcely any time for recovery. The oriental bubo-plague ravaged Italy sixteen times between the years 1117 and 1340. Small-pox and measles were still more destructive than in modern times, and recurred as frequently. St. Anthony's fire was the dread of town and country; and that disgusting disease, the leprosy, which in consequence of the crusades, spread its insinuating poison in all directions, snatched from the paternal hearth innumerable victims, who, banished from human society, pined away in lonely huts, whither they were accompanied only by the pity of the benevolent and their own despair. All these calamities, of which the moderns have scarcely retained any recollection, were heightened to an incredible degree by the Black Death, which spread boundless devastation and misery over Italy. Men's minds were every where morbidly sensitive; and as it happens with individuals whose sense, when they are suffering under anxiety, become irritable, so that trifles are magnified into objects of great alarm, and slight shocks, which would scarcely affect the spirits when in health, give rise in them to severe diseases, so it was with this whole nation, at all times so alive to emotions, and at that period so sorely pressed with the horrors of death. —[Hecker's Epidemics of the Middle Ages.]

*Excitability of the Female Imagination.*—The imaginations of women are always more excitable than those of men, and they are therefore, susceptible of every folly when they lead a life of strict seclusion, and their thoughts are constantly turned inwards upon themselves. Hence in orphan asylum hospitals and convents the nervous disorder of one female so easily and quickly becomes the disorder of all. I have read in a good

medical work that a nun, in a very large convent in France, began to mew like a cat; shortly afterwards other nuns also mewed. At last all the nuns mewed together every day, at a certain time, for several hours together. The whole surrounding Christian neighborhood heard, with equal chagrin and astonishment, the daily concert, which did not cease until all the nuns were informed, that a company of soldiers were placed by the police before the entrance of the convent, and that they were provided with rods, and would continue whipping them until they promised not to mew any more. But of all the epidemics of females which I myself have seen in Germany, or of which the history is known to me, the most remarkable is the celebrated convent epidemic of the 15th century, which Cardan describes, and which peculiarly proves what I would here enforce. A nun in a German nunnery fell to biting all her companions. In the course of a short time all the nuns of this convent began biting each other. The news of this insatiation among the nuns soon spread, and it now passed from convent to convent throughout a great part of Germany, principally Saxony and Brandenburg. It afterwards visited the nunneries of Holland, and at last the nuns had the biting mania even as far as Rome. —[Dr. Babington.]

*Napoleon's Character.*—These transactions throw as important a light upon the moral as the intellectual character of Napoleon. To find a parallel to the dissimulation and rapacity by which his conduct to Venice was characterized, we must search the annals of Italian treachery; the history of the nations to the north of the Alps, abounding as it does in deeds of atrocity, is stained by no similar act of combined duplicity and violence. This opens a new and hitherto unobserved feature in his character, which is in the highest degree important. The French republican writers uniformly represent his Italian campaigns as the most pure and glorious period of his history, and portray his character, at first almost perfect, as gradually deteriorated by the ambition and passions consequent on the attainment of supreme power. This was in some respects true; but in others the reverse; his moral character never again appears so base as during his earlier years; and, contrary to the usual case, it was in some particulars improved by the possession of regal power, and to the last moment of his life was progressively throwing off many of the unworthy qualities by which it was first stained. Extraordinary as this may appear, abundant evidence of it will be found in the sequel of this work. It was he same with Augustus, whose early life, disgraced by the proscriptions and horrors of the triumvirate, was almost overlooked in the wisdom and benevolence of his imperial rule. Nor is it difficult to perceive in what principle of our nature the foundation is laid for so singular an inversion of the causes which usually debase the human mind. It is the terrible effect of revolution, as Mad. de Staël has well observed, to obliterate altogether the ideas of right and wrong, and instead of the eternal distinctions of morality and religion, to apply to other test in general estimation to public actions but success. It was of this corrupted atmosphere that the mind of Napoleon, like that of Augustus, at first arose, and it was then tainted by the revolutionary profligacy of the times; but with the possession of supreme power, he was called to nobler employments, relieved from the necessity of committing iniquity for the sake of advancement, and brought in contact with men professing and acting on more elevated principles; and in the discharge of such duties, he cast off many of the stains of his early career. This observation is no impeachment of the character of Napoleon; on the contrary, it is its best vindication. His virtues and talents were his own; his vices in part at least, the fatal bequest of the revolution. \* \* \* United with the great qualities of Napoleon's character, was a selfish thirst for glory, and consequent jealousy of any one who had either effectually thwarted his designs, or rendered him such services as might diminish the lustre of his own exploits. His undying jealousy of Wellington was an indication of the first weakness; his oblivion of Kellermann's inappreciable service, an instance of the

second. When this young officer was brought into the presence of the first consul, after the battle, he coldly said, "You made a good charge this evening;" and immediately turning to Bessières, added, "The guard has covered itself with glory." "I am glad you are pleased," replied Kellermann, "for it has placed the crown on your head." He repeated the same expression in a letter, which was opened at the post office and brought to Napoleon. The obligation was too great to be forgiven. Kellermann was not promoted like the other generals, and never afterwards enjoyed the favor of the chief on whose brow he had placed the diadem. Napoleon, at the same time, was perfectly aware of the immense service rendered by the charge of Kellermann; for he said in the evening to Bouronne, "that little Kellermann made a happy charge. He struck in a critical moment; we owe him much." On what trivial events do affairs depend! —[Alison's Europe during the French Revolution.]

*Emigrants in America.*—A German emigrant generally remains in a large city only as long as he cannot help it; his great and laudable desire is always to get a farm, and to own it. The Irish are, in this respect very different; they prefer the cities, and wherever you meet with a populous place in the United States—I do not only speak of the Atlantic cities, but also of those in the interior, such as Albany, Utica, Cincinnati, Louisville, you are sure to find a great number of poor Irish in and about it. The German, as I said, pushes on; if he has not the means to proceed immediately to the west, and must take his temporary abode in a large place, it is only in order to save, as soon as he possibly can, the requisite sum to carry him and his family to those parts of the Union where land is cheap and fertile. Here again he has not perhaps, the means to purchase a few acres, though Government sells public lands for the low price of one dollar and twenty-five cents per acre. If this is the case, he will first work for another farmer; never, however, losing sight of his main object, the having a farm to himself. As soon as he has it, he loves it as a German trooper loves his horse; it becomes his "all in all," so that he sometimes forgets the proper mental education of his offspring. Scotch emigrants, I imagine, arrive here provided with sufficient means to begin farming immediately, and it is very interesting to see how the Scotch and Germans, among whom I count the Alsacians, since they are French in a political sense only, always show their natural predilections wherever the wide west offers them a fair chance of displaying it. The Scotch uniformly select hilly parts of the country, and dearly love their dairies. Germans prefer the water-side; they settle upon land bordering upon rivers and creeks. The German, the boldest of all in science and knowledge, is slow when he comes to acting; I mean the German who has not left his country, where, by its peculiar state of politics, brisk practical activity is so much cramped in its operation. When he sees other countries, and has free intercourse with their inhabitants, he generally finds his way uncommonly well; for though the German has, as things now stand, originally not much of a practical disposition, his versatility of mind is very great; which is proved as much by the truly noble height of criticism to which German science elevates itself, because it requires his entering into all the views of other nations, and ages, as by the success by which the German meets in all climes and under all forms of Government. A Frenchman shifts easier than a German; but his mind has not that degree of versatility to enable him to persevere in a totally new situation. A Yankee is bolder and shrewder than a German, and will often succeed where few others may hope for success; but he is not willing to labor as hard and plod as perseveringly, nor has he that knowledge of languages which the German naturally possesses. The German, in foreign countries, if a man of business, labors always under one great disadvantage; he is not backed and supported by a political nationality. Germans and French change, perhaps, more to their advantage, by travelling and collecting experience in foreign countries, than any other people; the former by obtaining more practical views of things, and learning to keep their diffusive thinking more within definite limits; the latter by becoming more liberal, more reflective, by expanding their

views beyond national vanity. However, who does not or ought not to improve in the latter way by travelling? Certainly, neither John or Jonathan is here excepted. Gothe says, "He who is ignorant of foreign languages is ignorant of his own." And, he who is ignorant of foreign countries is ignorant of his own.

*The Philosopher on Horseback.*—I never see the word "momentum" but it brings to my recollection an anecdote of an old friend of mine, a Fellow of a college, and a good fellow too, who was used to amuse me much by talking philosophically and mathematically on riding to hounds, the words *momentum*, *vis viva*, and *impetus* being forever on his tongue. With the nerves of a bull-dog, and no mean opinion of his prowess, he was in the habit of purchasing horses, which, from natural or acquired defects, had failed of making hunters in the hands of others. His idea was, that if nature had unfortunately intended such brutes to carry themselves in all forms but the right, that intention could be obviated by the means of mechanical force. To effect this, all sorts of trapping were resorted to; and it was really alarming to men with any nerves at all, to see him sailing across a country with the *momentum*, *vis viva*, and *impetus* all in full operation, on horses with manes like the hair of oak, but with their heads confined with a strong cavesson-martingal. On one occasion a most ludicrous accident occurred. This gentleman was out with the Duke of Beaufort's hounds, in Oxfordshire, on a horse thus accoutred, when the cavesson he was riding in unfortunately gave way. As may be expected, having no further power over the brute, away went the philosopher, like a ship at sea without a rudder, and, as ill-luck would have it, the *momentum*, *vis viva*, and the *impetus* all formed their nucleus in the person of an unfortunate butcher on his pony, who was going quietly along a road; and the two riders and their horses were laid prostrate on the ground. —[Nimrod's Hunting Torte.]

*Chinese Advertisement.*—The following is a specimen of the manuscript bills or advertisements, which it is the custom in China to stick up against the walls, when children have been stolen, apprentices have run away, &c.:—"Chang-Chaoulai, who issues this thanksgiving advertisement, lives outside the south gate in Great Tranquility lane, where he has opened an incense-smoking-mosquito shop. On the evening of the 19th instant, two of his fellow workmen in the shop, Neahung and Atik, employed a stupefying drug, which, by its fumes, sank all the partners in a deep sleep, during which they robbed the shop of all the money, clothes, &c. which they could carry away. Next morning when the partners awoke, no traces was to be found of these two men. If any good people know where they are and will give information, a thanks offering in flowery red paper of four dollars will be presented. Decidedly I will not eat my words. This advertisement is true. Neahung is about 20 years of age, short stature, has a white face, and no beard. Atik, whose surname is not remembered, is upwards of 20 years of age, is tall, and no beard. Reign of Taonk-wong, 9th year, 9th moon, 3d day."—[Mirror.]

*Discovery of Valuable Mines in the Pyrenees.*—"Two learned Mineralogists, Messrs. Malas Dietrich, have discovered in the Pyrenees, and described, above five hundred mines: some containing gold; others silver, copper, lead, iron, zinc, pyrites, fossil coal, &c. &c. Nearly one half of these mines have been opened; but nearly all of them as soon as glanced at abandoned.—This discouragement has followed the very first attempts; frequently through the ignorance of the miners; but nearly always from the want of communication with these high and remote regions."

[To remedy in some degree, the latter evil, it is proposed to extend the Canal of Languedoc from Toulouse to Bayonne.]

[Sterne has told us, "they manage these things better in France." How widows manage to get husbands there, the following advertisement from the *Courrier Francaise* of the 17th of last month, will show.]

\**Marriage.*—A widow, 46 years of age, without children, and possessing an income of 50,000 francs,

is desirous of uniting herself with a person who has seen the great world (*le grande monde*). Address Madame de Nantouil, rue de Bondy, No. 13, post paid."

*Invention to enable persons to descend into cellars, buildings, &c. when on fire.*—M. Paulin, Colonel in the corps of sapeurs-pompier, has invented a dress which covers the head and part of the body, without hindering the freedom of his movements, or depriving him of the power of seeing. It is fitted with pipes, by which he is supplied with the air necessary to sustain life; and with others by which he breathes it out again. The air is supplied from without by an ordinary pump. The experiment made has been perfectly satisfactory. They heaped up in the cellar of a hay barrack, wet straw, shavings, rosin, brimstone, &c. No sooner was the fire put to the heap than a thick cloud of fetid smoke issued from all the apertures. As soon as the fire was completely kindled, a pompier, protected by the covering of M. Paulin, descended into the cellar, and remained there 19 minutes. The stench of the exhalations which came out of the cellar during this time was such that no one could stand on the highest step of the cellar, without being instantly suffocated. They likewise closed the cellar door and the vent holes.

At length the pompier came up, (he had been provided, it should have been stated, with a pipe from a fire engine,) and he had completely extinguished the fire. Doubtless, the high temperature of the cellar on fire had rendered his situation one hard to bear; although he was continually refreshed by the air conveyed to him from without. They found his pulse beat at the rate of 130 per minute; and likewise that the metallic parts of the dress were very hot; notwithstanding, the experiment showed the possibility of conveying assistance where cellars are on fire, without risk to the life of those who undertake the task. It is an invention which renders us indebted to the zeal and ingenuity of M. Paulin.

[The invention would be applicable in many other cases beside those of cellars on fire.]

[From Blackwood's Magazine]  
The Last Journey.

Michael, in his description of an Egyptian funeral procession, which he met on its way to the cemetery of Rosetta, says,—"The procession we saw pass, stopped before certain houses, and sometimes receded a few steps. I was told that the dead stopped thus before the door of their friends, to bid them a last farewell, and before those of their enemies, to effect a reconciliation before they parted forever."—[Correspondance d'Orient, par M.M. Michael et Ponjoulat.]

Slowly, with measured tread,  
Onward we bear the dead  
To his long home.  
Short grows the homeward road,  
On with your mortal load,  
Oh, Grave! we come.

Yet, yet—ah! hasten not  
Past each remembered spot  
Where he had been;  
Where late he waited in gloom,  
There from henceforth to be  
Never more seen.

Yet, yet—ah! slowly move—  
Bear not the form we love  
Past from our sight—  
Let the air breathe on him,  
And the sun beam on him  
Last looks of light.

Rest ye—set down the bier,  
Ope he loved dwellings here.  
Let the dead lie  
A moment that door beside,  
Weak to fly open wide  
Ere he drew nigh.

Hearken!—he speaketh yet—  
"Oh, friend! wilt thou forget  
(Friend more than brother!)  
How hand in hand we've gone,  
Heart with heart linked in one—  
All to each other?"

"Oh friend! I go from thee,  
Where the worm feasteth free,  
Darkly to dwell.  
Giv'st thou no parting kiss?  
Friend! is it come to this?  
Oh, friend, farewell!"

Uplift your head again,  
Take up the mourning strain!  
Pour the deep wail!  
Lo! the expected one  
To his place passeth on—  
Grave! bid him hail.

Yet, yet—ah!—slowly move;  
Bear not the form we love  
Far from our sight—  
Let the air breathe on him,

And the sun beam on him  
Last looks of light.  
Here dwells his mortal foe;  
Lay the departed low,  
Even at this gate.  
Will the dead speak again,  
Uttering proud boasts and vain,  
Last words of hate?  
Lo! the cold lips unclose—  
List! list! what sounds are those,  
Plaintive and low?  
"Oh thou, mine enemy!  
Come forth and look on me,  
Ere hence I go."  
"Curse not thy foeman now,  
Mark! on his pallid brow  
Whose seal is set!  
Pardoning I passed away—  
"Thou—wage not war with clay—  
Pardon—forget."  
Now his last labor's done!  
Now, now the goal is won!  
Oh, Grave! we come.  
Seal up this precious dust—  
Land of the good and just.  
Take the soul home!

MILL-DAM FOUNDRY.

ON MONDAY, June 1, at 12 o'clock, at City Hall, (unless previously disposed of a private sale,) will be sold by auction, the above well known establishment, situated one mile from Boston. The improvements consist of—

No. 1. *Bell House*, 50 feet by 30 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. *Blacksmith's Shop*, 50 feet by 30, fitted with cranes for heavy work.

No. 3. *Locomotive House*, 54 feet by 25, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with slate, 130 feet by 40, containing two water-wheels, equal to 40 horse power; Machine Shop, filled with lathes, &c.; Pattern Shop; Rolling Mill and Furnaces, capable of rolling 4 tons of iron per day, exclusive of other work; three Trip Hammers, one of which is very large; Engine for blowing Cupola Furnaces, moved by water-wheel; one very superior 18 horse Steam Engine, which could be dispensed with; and a variety of other machinery.

No. 5. An Iron Foundry, 80 feet by 45, with a superior air Furnace and two Cupolas, Core oven, Cranes, &c. fitted for the largest work. Attached to the Foundry is a large ware-house, containing Patterns for the Castings of Hydraulic Presses, Locomotive and other Steam Engines, Lead Mill Rolls, Gearing, Shafts, Sproves, Grates, &c. &c. These were made of the most durable materials, under the direction of a very scientific and practical Engineer, and are supposed to be of great value.

No. 6. A building, 65 feet by 35, containing a large stock of channels, and furnaces, for making Cast Steel. This building is at present used as a boarding-house, and can accommodate a large number of men.

No. 7. A range of buildings, 300 feet long by 36, containing counting room, several store rooms, a Brass Foundry, room for cleaning castings, a large loft for storing patterns, stable for two horses, &c. &c.

The above establishment being on tide water, presents greater advantages for some kinds of business than any other in the United States. Coal and iron can be carried from vessels in the harbor of Boston, to the wharf in front of the Factory, at 25 to 30 cents per ton. Some of the largest jobs of iron work have been completed at this establishment; among others, the great chain and lift pumps for freeing the Dry Dock at the Navy Yard and Charleston.

The situation for Railroad work is excellent, being in the angle formed by the crossing of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at these works. With the Patterns and Machinery now in the premises, 12 Locomotives and as many tenders, besides a great quantity of cars and waggon, could be made per annum.

For terms, apply to

THOS. J. ECKLEY, Treas. &c., Boston, or to  
ROBERT RALSTON, Jr., Philadelphia.

Boston, April 21, 1835.

PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to. HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by I. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 229 Waterstreet, New York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; DeGrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

**Stocks Higher and Higher.**—The Bulls have it all their own way. The Bears suffer most awfully. On Friday several descriptions, which had been deemed too high, took a fresh start—Dry Dock up to 145, higher, we believe, than any Bank stock has sold at in ten years; Mohawk Railroad sold at 130, an advance of twenty-five per cent. in five months. We give the following, to show the most extraordinary rise in stocks in five months.—[Daily Adv.]

[From the Portland Advertiser.]

**Good News from Quebec.**—We understand that Gov. Dunlop has received a letter from Lord Aylmer, the Governor General of British America at Quebec, stating in substance that he and his government are ready to meet ours in a survey of the route for the proposed Railroad from our Atlantic Sea Board to Quebec, whenever our Government shall appoint the necessary Surveyors and Engineers. The Report in our Legislature on this subject, we are informed, has attracted the attention of the Quebec and Montreal papers, who have republished it and commented upon it at some length. The Montreal people feel but little interest in it, as they have comparatively an easy communication with the Atlantic via New York. But the Quebec people look to this city as their grand outlet and inlet, particularly in the winter, spring, and the months of October and November. The republication of the report in our Legislature in the Quebec newspapers, with the interest felt by the Quebec public in the establishment of such a communication, induced Lord Aylmer to enter upon the subject with zeal—and therefore, he has tendered a co-operation in a survey, to the Governor of Maine. Probably Lord Aylmer, as Governor of Lower Canada, has under his command a corps of Engineers attached to the army stationed at Quebec—or has the power of defraying the expense out of the income arising from the sale of the crown lands—for it seems that he has the power to make the Canada part of the survey without an appropriation by the Colonial Legislature.

**Portugal.**—The sale of the National property is expected soon to take place, and it is said that orders for purchasing £100,000 worth of it have arrived from different persons in England. Mr. Creig, an English Engineer, is about to Macadamise the road from Lisbon to Cintra. The road between Lisbon and Oporto is also to be improved. The new Minister of the Interior has begun his career well with these improvements in the means of communication.

**Lafayette's Tomb.**—A simple slab of black marble in the burying ground at Plopar, in Paris, marks the spot where repose the remains of Lafayette. It bears this inscription:—"Here lies M. P. J. R. C. M. de Lafayette, Lieut. General, Deputy, born at Auvergne, in 1757; married 1776 Mlle. de Noailles; died in 1834; Requiescat in pace"

## PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-14

## RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of EIGHT pages, devoted mainly to the subject of internal improvements, in all its various modes and forms. Three volumes were completed in December, 1834, and the 4th volume is now in progress. Terms, \$3 a year, in advance. Previous volumes same price; full set of four volumes, \$12.

## RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$2.

## MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has completed 4 volumes, or two years. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, in advance. Previous volumes \$1.50 each.

## THE APPRENTICE'S COMPANION.

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* \* All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY-THREE for \$10. D. K. M.

## NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

## QUARTERLY JOURNAL OF AGRICULTURE, MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$5, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 230 pages.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher, D. K. MINOR, 35 Wall street, New-York.

## RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle & Furnace and Machine Shop, will make to order cast wheels, chairs and knees, and every other description of castings required for railroads. R-1y 1614

## STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads.

No. 204 Elizabeth street, near Blacker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J36 tf

## RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.  
Also, Flange-Tires turned complete.

J8 ROGERS, KETCHUM & GOSVENER

## PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory. Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water. Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept 13 y

## RAILWAY IRON.

95 tons of 1 inch by 1 inch.	Flat Bars in lengths of
200 do. 1½ do. do.	14 to 15 feet, counter sunk
40 do. 1½ do. do.	holes, end cut at an angle
300 do. 2 do. do.	of 45 degrees, with eye
300 do. 2½ do. do.	clipping plates and nails to
soon expected.	suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins. Wrought Iron Rims of 20, 23, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels. Axles of 2½, 3, 3½, 4, and 5 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d11mawr

## SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by E. & G. W. BLUNT, 154 Water street, corner of Maiden lane. J21 6t

## SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes. WM. J. YOUNG.

Mathematical Instrument Maker,  
No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1832.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of this kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely anything to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLER, Supt of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833. Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

German town, February, 1833.

For a year past I have used instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad. mi 1y  
German and North. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, MAY 9, 1835.

We have been furnished with a copy of the proceedings of a meeting held at Norwich, Conn., on the 29th of April, in relation to the railroad from Norwich to Worcester, for the purpose of opening an easy communication between Boston and Long Island Sound, and of course with New-York, which will be found on the 5th page of this number. This road will pass through a thickly populated and wealthy part of the country, which abounds in those productions that will, aside from the immense travel which will pass over it, insure, we doubt not, a good return upon the investment. Norwich will not quietly relinquish to Providence and Stonington the entire business between New-York and Boston, but with a spirit which does her credit, and which will ensure her success, enters the field, and will contend manfully for the prize—a prize indeed well worth her utmost efforts; and it is time that her citizens awake, as we perceive that the commissioners of the Long Island Railroad have given notice of their intention to open books to receive subscriptions for stock.

It is therefore important that those who mean to contend successfully for the business, should be ready to connect with that road when completed, as completed it surely will be.

We have been requested to call attention to the Great Au Sable Railroad, from Port Kent on Lake Champlain, to Keeseville. The following article was furnished us by a gentleman who is perfectly familiar with the business of that vicinity, and he assures us that it will prove a good investment.

**GREAT AU SABLE RAILROAD.**—This road runs from Port Kent, on Lake Champlain, to Keeseville, on said river, 5½ miles. It was laid out by Major Beach, civil engineer of Newark. His report to the President was published in detail in vol. 3, p. 50, by which it will be seen from statistical documents, that upwards of 50,000 tons would pass over the road in the offset, yielding a neat income of 20 per cent., and constantly increasing, to which may be added, that the charter extends to 50 years, and that the amount of produce is unlimited; and that the road can be made for \$6000 a mile, the materials being along the route.

We can safely recommend this stock to our friends, as among the most certain and productive in the United States. Capital stock, \$60,000; 1200 shares at \$50, 500 of which have been taken near the road. The residue, we are informed, will be in market next week, with explanatory maps, &c. It is contemplated to finish the road in October next. John T. Norton, President; Robert Gilchrist, Treasurer; Ephraim Beach, Chief Engineer.

The United States have also caused a breakwater to be laid off in front of the harbor of Port Kent, which has been acted upon by Congress, and will doubtless go into effect the ensuing year.

Our readers must know that Port Kent is the outlet of what is emphatically called the Sweden of America.

[From the Baltimore American.]

New York is alarmed for her Western trade, and well may she be. Pennsylvania has the shortest, cheapest and quickest line of communication between the West and the Atlantic, and we venture to assert without hesitation that her immense line of Canals will in a short time be as much thronged with trade as those of New York now are.

By the recent act of Pennsylvania, authorizing the extension of her Canal from Columbia down to the Chesapeake, Baltimore is placed in a position which gives her a direct and very large interest in all that concerns the Internal Improvements of that State. The opening of the extension Ca-

nal—Columbia being but forty miles from the tide waters of the Chesapeake—will unite our city with the Pennsylvania Canals by an unbroken water communication which will render the Baltimore market of easier and cheaper access than any other on the sea board. A share—a very large share—of the trade of Pennsylvania and of the great West, will descend to the Chesapeake through the Extension Canal, and make its way to us. This short work, at the first moment of its completion will turn the course of this immense trade in this direction, and if the undertaking is taken up and prosecuted with vigor and efficiency commensurate with its importance to those who are directly concerned in its successful accomplishment, it may be in full operation by the spring of 1837. The Maryland Canal, reaching from Port Deposit to the State Line, can easily be enlarged to the requisite dimensions while the remaining thirty miles between the Line and Columbia, divided into half mile sections, are being constructed. The friends of the work have only to determine that it shall be finished by the end of 1836, and will it be done.

**Trenton Trade.**—New evidences of the prosperity of our city, are daily opening upon us. A year ago, and our "Editor's attic" was in the most retired and quiet part of the town—now, the din of masonry, carts, and falling lumber, is in our ears—huge piles of stone, brick, and plank, are around our doors—and just before our window, proudly floating on the breeze, rolls our national flag, from the mast head of a gallant schooner. We walked out to make acquaintance with the stranger, and found her to be the *Caroline Frances*, a trim built craft from the New York ship yards, taking in a cargo of lumber, grain, flour, tar, Indian meal, &c. for the Eastern markets. She is the first of a regular line of packets owned by our enterprising citizens, Messrs. Rose, Green, Hoy & Co., intended to ply constantly between this place and New York. This brings the up-river trade of the Delaware in rivalry with the trade of the Hudson, and enables East Pennsylvania and New Jersey to throw their produce into the Eastern markets, with as little, if not less, freight and duties than the interior of New York. Besides, goods stored at Trenton have this advantage—should sales in the Eastern market be dull, the Southern are of still more easy access.

During the day, the *Caroline Frances* passed round from the Feeder Basin to the Trenton Basin, and there now waive her stripes and stars over the very fields where first that flag won the respect of its enemies, and the adorations of freemen—the Battle Field of Trenton.—[Trenton N.J. Emporium.]

To the Editor of the Am. Railroad Journal:

SIR,—What objection could there be to using a steam engine on the towpath of a canal?

Will some one of our readers who has leisure, answer this "query?"—[Ed. R. J.]

*Macneill on Canal Navigation.*

(Continued from our last number.)

With this boat the results exhibited in the following tables (II. III. IV.) were obtained on the Paddington canal, opposite Holsden Green. The important effects which they are calculated to produce in the minds of the unprejudiced, not only upon inland navigation, but to nautical science in general, have determined me to publish them in the fullest manner, giving every particular connected with their arrangement, as well as the names of those scientific gentlemen who assisted me, together with the names of the assistants from my own office, so that the most ample evidence of accuracy and care may be had. For more advantage will be derived by accurate trains of experiments than will follow from the assumptions of a mathematical century.

The first requisite was a good dynamometer for measuring the tractive force necessary to move the boat at various velocities, and as I showed a marked preference for my own, with which I had obtained such important results during my surveys of roads for the parliamentary commissioners, I shall give a description of it, in order that readers may be satisfied such preference was justly given.

The dynamometer or pirameter, I originally intended for measuring the draught of carriages on turnpike roads, and for this purpose I have used it very extensively under the Parliamentary Commissioners, for the London and Holyhead road, and elsewhere. The following is a description of the instrument, and in the appendix (B) will be found the opinions of competent judges upon its merits. When I at first endeavored to adapt Marriot's spring weighing machine, so as to ascertain from it the amount of the horse's draught, the stepping motion of the horse created a quick succession of vibrations, which completely prevent any one from reading off the figures indicated—and this confusion of vibrations will always prevent the simple adoption of any species of spring weighing machine. To remedy this inconvenience, and do away with the vibrations as much as was necessary, I applied a piston, working in a cylinder full of oil, and connected with the spring in such a manner that when any power or force is applied to it, so as to make the hand traverse the index, the piston is at the same time moved through the fluid. The connection of the spring and index with the cylinder is by means of a lever working on a pivot: the arms of the lever are of unequal length; the tail-piece of the spring and index is connected with the short arm; at the extremity of the long arm the piston rod is connected; the piston rod, after passing through a stuffing-box in the cap of the cylinder, is screwed into a piston or circular plate of thin brass, perforated with small holes; and out of one part of the circumference a square notch is cut, the use of which will be seen below.

By this construction, the resistance of the fluid to the piston, which acts at the extremity of the long arm of the lever, prevents the sudden jerks of the horse from being marked with those vibrations on the index so much to be avoided; at the same time the piston will move over a space proportioned to the intensity of the force exerted by the horse, and the same will be indicated accordingly upon the dial of the instrument; if the pulls follow each other in rapid succession, the piston will move slowly out, and the hand upon the index will turn round steadily and uniformly, until the power is balanced by the spring.

The dial is graduated in pounds, and decreases from zero upwards, in order to compensate for the increased force which the spring exerts in proportion as it is wound up; in consequence of this the index does not pass over equal spaces when equal forces are applied in different states of tension of the spring: the piston therefore will not pass through equal spaces in the cylinder, and the vibrations would consequently be greater in the higher numbers, because the velocity of the piston being less, the resistance to the piston in passing the fluid will be less, at the same time the power opposed to it is greater. To obviate this, and to make the index equally steady on all parts of the dial, a narrow slip of brass, formed into an inclined plane, is soldered to the inside of the cylinder, parallel to its axis, the largest (or highest) part of this inclined plane being at that end of the cylinder towards which the piston rises when the index moves towards the greater power. The notch which is said above to be cut in the circumference of the plate, (which traverses like a piston in this cylinder,) corresponds in size exactly with the largest part of this inclined plane; so that when the piston is at the upper end of the cylinder, the notch is completely filled up by the inclined plane; on the contrary, when the piston is at the lower end of the cylinder, the aperture is completely opened. By this contrivance the aperture through which the fluid is obliged to pass, as the piston moves from the lower end of the cylinder to the higher, is gradually contracted, and of course the resistance to the passage of the piston through the fluid is gradually increased, and thus compensates the increased power of the spring; rendering the vibrations nearly uniform from the lowest to the highest power. This compensation is similar to that by which the fusee regulates and gives uniform power to the main-spring of a watch.

This instrument\* was placed in the doorway of the front cabin, (which is about fourteen feet from the stem of the boat,) and in a line with the ordinary tugging hook; secured with wooden braces and screw nails in such manner as to be perfectly firm and steady, in some instances the towing line was made fast to the weighing bar of the dynamometer, and the power communicated directly to it. In other cases the towing line was made fast to a shackle on an iron lever, the fulcrum of which was the screw bolt which made the bar fast to the gunwale of the boat on the bow nearest the towing path; the power being communicated from the lever to the dynamometer by means of another shackle; this last mentioned shackle being precisely twice the distance from the fulcrum. By this arrangement we were enabled to bring either the whole tractive force to be indicated on the dial plate at once, or only one half that power, as we please, by merely shifting from one position to the other.

I consider this arrangement to be advisable, lest by any chance there should have been an error in the graduation of the dynamometer. To prove its accuracy, we repeated most of the experiments with and without the lever. If when the power was communicated to the weighing bar of the dynamometer, the instrument indicated the whole traction to be one hundred pounds, and if, when the power was communicated

\* In the modification of this instrument, which I have now mounted in a light double-bodied phetion, the dial plate is fitted, not only with an index and hand, but also with a card for determining the bearing; a pendulum which shows, by means of an index and hand, the inclination; a time-piece; and an index and hand to show the distance travelled by the wheels.

to the other shackle, the instrument indicated only fifty pounds, we were warranted in concluding, that as far as this experiment was concerned, the dynamometer was accurate. Now this I had done on numerous occasions, to prevent the possibility of error; and in order to be more perfectly assured, I repeatedly employed weights, suspended over a pulley, to check the dynamometer.

In making the observations with the dynamometer, every care was taken to have accuracy. Mr. Whitwell kindly assisted me in all these observations. He took the time with an excellent watch, having a detached second hand, with a dead beat, which enabled him to give a signal very accurately at intervals of two seconds. At these signals the power of traction indicated by the dynamometer was read off silently and distinctly by two gentlemen, whose names are at the head of their respective copies. Each of these gentlemen added the observations together, and took the means of each set.

Whilst these observations were making at the fore sheets of the boat, the times of the boat's passage were noted a little farther aft, by Mr. Turnbull and Mr. Dundas, who had each an excellent chronometer (from Arnold and Dent's.) The word "time" was given by Mr. Wilson, when the boat passed the stakes which had previously been driven in the embankment at distances of one hundred yards apart. By this means the observers of the time had never occasion to lift their eyes from the chronometers, except to note down the observations.

Besides the gentlemen making these observations, I was always assisted by others; but more especially by Mr. Alexander Gordon and Mr. Saxton, both of whom being so well qualified from their practical and scientific acquirements, for such a series of experiments, contributed very materially to prevent errors from taking place, by a general view over each department.

Fig. 3 represents a transverse section of the Paddington canal, opposite the village of Holsden Green; the soundings and measurements having been taken by Mr. Bourne and Mr. Turnbull.

[In the following experiments great care appears to have been taken to ensure accuracy; as the time of passing each stake, placed at 100 yards distance from each other, was marked by two first rate chronometers, and a full account of each is given, both the moment of passing each and the time between the stakes. It is not, however, deemed necessary here to give the separate statements of each time-piece—but merely the mean time of passing over the space of 100 yards between each stake, the velocity of passing, the mean force of traction as observed, and the weight of passengers in lbs., &c.]

In Table II., the first ten experiments are not published, because the arrangements were not, at that time, as perfect as could be wished. The length of the horse line was 82.1 feet; girth, 1.7.8ths; weight, 10 lbs. 1 oz. The length of the light line was 68.1 feet; girth, 7.8ths; weight, 2 lb. 8 oz. The standard adopted for calculating the squares and cubes of the velocities in the experiments mentioned in this table, and all those made on the Paddington Canal, was 2.517 miles per hour.

In Table III., experiments 5, 6, 7, 8, were made by a weight over a pulley; no accurate result. Experiments 13, 14, 15, 16, were also made by a weight over a pulley.

TABLE II.—Experiments made with the "Graham and Houston" Iron Boat, on the Paddington Canal, for the purpose of ascertaining the law of resistance, or force of traction at different degrees of Velocity. 8th April, 1883.

No. of Experiments.	Mean time of passing over 100 yards between each stake.	Velocity in miles per hour.	Mean Force of Traction in lbs., as observed.	Mean Force of Traction, calculated from the squares of the Velocities.	Mean Force of Traction, calculated from the cubes of the Velocities.	Weight of Passengers in lbs.	Wind ahead, but scarcely perceptible.

APPENDIX.

A.  
Specification of a Light Iron Passage Boat, such as ply on the Summit Level of the Forth and Clyde Canal, between Port Dundas and Windford, and such as was used in the Experiments detailed in the foregoing paper.

Extreme length, 70 feet; do. breadth, 54 feet. The iron of the very best manufacture. The body plates in particular must be free from rust, cracks, blisters, and roughness of every description. The whole of the iron must be coated with linseed oil, previous to its being used. And the boat must be built under cover, so that the work may be kept dry until the boat is finished.

Although not shown on the plan, the said boat has a hollow keel, so as to prevent the lodgement of water beneath the floor, between the ribs. The stem and stern shall consist of bars of iron, six inches in breadth, and a quarter of an inch thick, which are hammered flat at the lower part to the breadth and thickness of the keel-plates, to which they are scarfed and secured with clenched rivets.

As stated above, the keel-plates are formed hollow, and consist of hoop iron, six inches in breadth, and one eighth of an inch in thickness. To which a wood keel of Mahoe plank, fifty feet in length, nine inches in depth, three inches in thickness next the bottom at the each end, and a into distance. The iron, of two tenders being built, two rows of holes are punched on the flat side of the angle and T ribs to secure the body plates, and holes at convenient distances are punched through the upright flange to secure the false ribs for the inside lining.

The body-plates must consist of the best double rolled No. 16 sheet iron, two and a

half lb. per superficial foot, and these sheets are in lengths of eight and ten feet. The first range of bottom plates which join the hollow keel, eight feet in length and 24 inches in breadth; the next two ranges on each side which form the bilge, ten feet in length, by twelve inches in breadth, and the range next gunwale, ten feet in length by eighteen inches in breadth. Particular attention is requisite, both with the view to the strength and appearance of the boat, that the whole of the body-plates be run in fair sheer lines from stem to stern, and that the lower edge of each succeeding length or range of plates cover the upper edge of their accompanying ones, three quarters of an inch, so that the boat in every respect may have the appearance of being clencher built.

The butts, or end joints of the plates, must be kept smooth, and meet on the centre of the T rib, and the joints of each succeeding plate be so shifted as to meet on the T rib nearest the centre of its accompanying ones. It must, however, be expressly understood, that previous to any of the plates being rivetted, a thin stripe of cotton cloth, dipped in white lead paint, be put in between the overlaps of the edge joint, and between the ribs and the end joints, so as to prevent leakage and corrosion. The whole end and edge joints must be secured with countersunk rivets, made from a three-sixteenth of an inch bore, placed at the distance of three fourths of an inch from centre to centre, and made from the best charcoal rivet iron; the rivets, except those for securing the end joints, must be placed two inches distant from each other, and the whole, as stated above, be countersunk, and kept as smooth as possible.

Plates, six inches in breadth, and one eighth of an inch in thickness, to be placed on each side along the bilge, over the body plates, where they are most exposed to injury when taking on board and landing passengers, which will extend from the round of the entry, at the bow, to the commencement of the run or exit at the stern, and is secured to the ribs and body plates with countersunk rivets, placed at the distance of three inches apart; but before they are secured, both the bilge plates and body plates must be properly coated with white lead paint, and a ply of sheathing dipped in the same, put in between.

One and a quarter inch of angle bars extend from stem to stern, to form the gunwale, to which welts or wood mouldings are secured; and another of the same dimensions to be placed seven inches below the gunwale, to which the wood-belt, three inches thick, and four inches deep round off, is to be secured.

The boat is framed and moulded, and in every respect formed exactly and agreeably to the plan, and the work must be done in a substantial and workmanlike manner.

#### *Specification of the Carpenter and Joiner Work of such a Light Iron Canal Passage Boat.*

The length of the boat as specified, at seventy feet in length, five feet six inches in breadth, and two feet six inches in depth. It is divided in the following manner, viz. Fore deck, 4 feet in length; fore sheets, space for steerage cabin and principal cabin, &c., and after sheets, according to the number of the travellers intended for; after deck, 4 feet.

The false ribs for securing the inside lining consist of willow timber, one inch in breadth, and seven-eighths of an inch in deepness, which must be free from knots and shakes, so that they may bend easily after being stoved to the curved form of the

boat, to which they are secured with nails, rivetted to the upright flange of the ribs.

The sea-crofts, fore and aft, must extend from the stem and stern to the end of the cabins, and be four inches in breadth, and two inches in thickness, of best Memel plank, which is kept flush with the gunwale inside, and secured with three-eighths of an inch rivets, one throughout each rib.

Two timber heads on each side, near the bow and stern, are placed in the most convenient situation for mooring the boat, and secured with glands fixed with clenched rivets, so that the timber heads may be taken out and replaced when found necessary; to consist of solid oak timber, five inches in breadth, two inches thick, one foot in length below the gunwale, and seven inches above.

The beams which support the deck fore and aft, consist of oak plank two inches thick, three inches deep in the centre, and two inches deep at each end, with a curve of half an inch to the foot in length; and they are secured with a sheet-iron plate to the gunwale, angle iron, and sea-croft.

The gunwale or covering boards should consist of the best Memel fir plank, one inch in thickness, which extends from stem to stern; the cover is secured to the gunwale flange and wale that forms a moulding round the same.

The ends and divisions of the cabins should consist of Memel plank, two and a half inches in breadth, and one and three-fourths inch thick, which will form diagonal frames, for the purpose of strengthening the boat, so as to resist external pressures. The said frames must be lined at the ends of the cabins outside, with the best half-inch American yellow pine plank. The framing in the inside of the cabins may be lined as may be approved of.

The sleepers, for support of the flooring, should be two inches deep, by one and a quarter inch thick, placed and fitted to each alternate rib, and fixed to the upright flange with rivet nails. The flooring should consist of the best yellow pine plank, one inch thick, and not to exceed six inches in breadth, which must be properly cleaned, ploughed, and feathered.

The height of the cabins, from the top of the floor to the lower part of the beams, six feet at the centre, and the height of the sides above the level of the floor will be five feet under the beams, consequently the beams will have a curve of twelve inches.

The standards or stanchions of the sides of the cabins should consist of the best white American oak, one inch thick, and one and a half broad at the gunwale, and one inch in breadth at the top of the cabin, and placed at each alternate rib, to which it is secured, the distance being twenty-four inches from centre to centre. The top gunwale, for the support of the roof, to be made of the best Memel fir or red pine, free of blemish or knots, and extend the whole length of the cabins, two and a half inches deep outside; the upper edge is bevelled to suit the curve of the beams, and two inches in thickness, mortised to fit the tenure of the standard, having a projection for a bead, and thickness of outside lining.

The beams, as stated above, to have a curve of twelve inches, to consist of the best clean ash timber, an inch and a half in breadth, by one inch in depth, the lower part rounded to a half-circle, and is placed at the distance of two feet from centre to centre, dove-tailed and secured to the gunwale with screw-nails; and a framing of iron wire gauze, well painted, shall be

made to connect them, so that the top may form one solid connected form from end to end.

A stringer extends the whole length of the cabins in the centre to support the roof, which is let in, and bound to the diagonal frames, the upper edge kept flush with the top of the curve, consisting of clean solid white Quebec oak timber, three inches in depth, by an inch and a half thick; into which the beams are let nearly in the whole depth, and made exactly for the top covering.

The space outside of the cabin, fore and aft, must be lined from the floor to the gunwale with five-eighths of an inch red pine boards, and seated in the usual form; the tops seven-eighths of an inch thick, with round supports and cross bearers, with two front rails, two and a half inches in breadth, beaded, and let in flush with the bottom and top of the supports or feet.

In order that the boat may be kept as light as possible in the fittings-up, there should be no inside lining of wood from the floor up, consequently the whole seatings in the cabins must have fronts supported with brackets; these brackets to be secured to a stringer, fixed to the sides of the boat the whole length of the cabin, three inches in breadth, by an inch and a quarter thick, to which the brackets are let in flush, and nailed to it and the floor. The seats in the principal cabin to be sixteen inches in height, so as to allow cushions two inches thick and eighteen inches in breadth; the back to be one inch lower than the front, which is considered an improvement as a comfortable seat; the seats in the principal cabin may consist of cane, light wood, or lacing, as may be approved of; the fronts consisting of the best American yellow pine five-eighths boards. The seats in the steerage, eighteen inches in height, by fourteen inches in breadth, and fixed with brackets in the same manner as the principal cabin, and be seven-eighths of an inch in thickness.

The outside lining between the gunwale and top of the cabins should consist of the best yellow pine half-inch boards, well seasoned, free of knots, sound, and properly cleaned, ploughed, and feathered. The first board will extend the whole length of the cabins, eight inches in breadth, neatly joined to the covering boards, thin fitters being fitted between the standards or stanchions, and, laid in white-lead paint, so as to be water-tight, is fixed to the side standards with springs.

The space between the standards being twenty-four inches from centre to centre, it is proposed that light windows or patent gauze wire shall be placed in every alternate space, so as the passengers may have a view of the country without being under the necessity of removing to the outside. These windows and frames should be made as light as possible, and made to slide or fold, as may be considered most convenient.

The inside lining, from the seats up, and between the windows, should consist of oil-cloth, fixed and finished with beads and facings.

The top or cover of the cabins to consist of oil-cloth, which must be perfectly water-tight, and fixed to the beams, top gunwales, and ends of the cabin, with a moulding. It will be necessary to have a thin sheet of plate-iron for the funnels, so as to prevent any danger from the heat of the stoves during the winter.

The outside doors should consist of red pine plank, one inch and a quarter thick, bound and pannelled, to be hung with neat

light bats and bands, have good five-inch rimmed locks, brass mounted, to open out in two halves, and to have small brass slip bolts at top and bottom. The doors in the divisions to have check locks, and hung with five-inch edge hinges.

The inside doors should consist of the best yellow pine plank, one and one-eighth inch thick, and twenty-two inches in breadth, and finished with facings.

That the whole of the inside, previous to the joiner work being commenced, should have two coats of good lead color paint, and the whole of the iron-work on the outside, as well as the wood-work in the outside and inside, should have three coats of paint of different colors, and finished in a sufficient and workmanlike manner.

(To be continued.)

[For the American Railroad Journal.]

# Railroad Meeting.

In pursuance of public notice a meeting of gentlemen interested in the railroad from Norwich to Worcester, was held at Norwich in the Town Hall on Wednesday evening last—J. G. W. Trumbull in the chair, L. F. S. Foster, secretary.

M. J. A. Rockwell, from the committee appointed at a former meeting to collect and furnish facts connected with the subject, presented a full report. This report contains a mass of interesting and important matter in relation to the proposed road, which will be laid before the public. Mr. Rockwell read such portions as he judged had the most direct bearing upon the question, from which it appears,

1. That the route of the Norwich and Worcester railroad is a direct route to Worcester by the valleys of rivers, through a country in every respect favorable, with an elevation to be overcome in no point of more than 30 feet per mile, and the average elevation of 11½ feet per mile, and that the materials of construction are at hand, and the expense would be unusually small.

2. That within five miles of the route there are 75 cotton manufactories, 27 woolen mills, about 100 stores, and numerous mills for the manufacture of iron, paper, &c. That the number of cotton spindles employed in the two counties in Connecticut through which this railroad passes, is officially ascertained to be 100,229, being more than three fourths of the entire cotton manufactories in this state; and that there is probably nearly an equal amount in the county of Worcester, and that there is not in any part of this country a region so abounding in manufactories as on the borders of this route.

3. That the present amount of transportation to market from towns very near, and on the borders of this route, is at least equal to thirty thousand tons annually transported through the entire route, and would be greatly increased by transportation on the borders of the Boston and Worcester Railroad, from Boston, and from the country north of Worcester.

4. That there is unoccupied water power on and near the borders of this route, ascertained by actual surveys to be not less than sufficient to carry 1,000,000 spindles.

5. That there are in various places on and near the route, valuable stone quarries, for building; and in the town of Killingly inexhaustible quarries of flagging stone, pronounced by Professor Mather superior to any flagging stone now in use in this country.

6. That the railroad from Norwich to Worcester, and from Worcester to Boston, passes through the most populous part of this country; and that the counties through

which these railroads will pass, exclusive of the county embraced by Boston, contained in 1830 a population of 273,606, and that there is a population north of Worcester, and of the railroad from Boston to Worcester, which would find this the most direct route to New-York, not less than 250,000, exclusive of Boston.

7. That the route by railroad from Boston to Worcester and Norwich, and thence by steamboat to New-York, is 100 miles by railroad, and 130 by steamboat; and when completed, the passage may be made in 16 hours, and is the best existing route between Boston and New-York, being the easiest, cheapest, most direct, and rapid.

8. That the route from Boston to Worcester may be readily reduced to 88 miles; that Norwich is within three miles as near New-York as Stonington, and the route from Boston by the way of Norwich, to New-York, would be as near as by way of Stonington.

9. If a railroad is constructed on Long Island, the distance from Norwich to its termination is 28 miles, and from Stonington 25 miles—enabling the Norwich and Worcester railroad to avail themselves equally well of the Long Island railroad.

10. That a railroad constructed on the borders of Long Island Sound would accommodate the long travel, it being estimated that the number of passengers annually passing in the steamboats between New-York and the towns on the borders of the Sound is not less than 300,000; and that the distance from Norwich to New-York is 130 miles, and from Stonington to New-York, including two ferries, is 122 miles.

11. That by the extension of the Railroad communication to Lowell, and thence farther north and east, every part of the chain is benefitted, and this route greatly improved.

12. That the extension of the Boston and Worcester Railroad to Springfield, and thence to Albany, by opening the valley of the Connecticut, and affording a railroad communication with the interior of New-York and the west will add to the revenue of this railroad.

The following resolutions were offered by Mr. C. W. Rockwell, and unanimously adopted:

1. Resolved, That this meeting consider the valleys of the French and Quinebaug rivers as affording the natural and most inviting route for a railroad from Worcester to Long Island Sound.

2. Resolved, That inasmuch as the survey of this road is entirely through a valley, crosses no hills, and abounds with the best materials, the construction of a railroad can be effected at an expense much below any other route.

3. Resolved, That since the contemplated route for a railroad from Norwich by Worcester to Boston, is through a section of country the most populous of any in the Union, there must be a support for passengers on the borders of this route, unequalled by any road now in operation or contemplated.

4. Resolved, That the amount of transportation and travel, from upwards of one hundred cotton and woollen manufactories, and from one hundred stores on the line of the road, make it certain that ample remuneration will follow the immediate construction of it.

5. Resolved, That the unemployed water power on and near the line of this road, (equal to the operation of at least five hundred thousand spindles,) the almost inexhaustible supply of ship timber, the quarries of building and flagging stone, present

additional inducements that urge most strongly to the early completion of the work.

6. Resolved, That since, by a branch not exceeding 5 miles, to the Boston and Worcester Railroad (at Millburg), Boston will be brought within about 88 miles of Norwich (the same distance as Stonington,) this route between New-York and Boston, is within three miles as near as by Stonington and Providence, and is at least equally favorable, since it avoids that part of Long Island sound which is often boisterous.

Resolved, That the construction of a railroad upon Long Island will benefit the road from Norwich to Worcester, to the same extent as the Providence and Stonington route, since from Greenport, the eastern termination of the Long Island road, the distance to Norwich is only three miles greater than to Stonington, and to counterbalance this, the distance in the Sound is 10 miles less.

8. Resolved, That as charters of the most favorable character have been granted for this route by Connecticut and Massachusetts, it is important that measures be immediately adopted to prosecute this great enterprise.

9. Resolved, That it be recommended, that a convention of delegates from the towns on the borders of the route be held at Norwich on Wednesday the 10th of June next, for the promotion of this object, and that a committee be appointed to make arrangements for the same.

The following gentlemen compose that committee: C. W. Rockwell, W. C. Gilman, James L. Ripley, John Breed, and Asa Child.

The meeting was addressed by Messrs. J. A. Rockwell, W. C. Gilman, P. Lanman, C. W. Rockwell, John Breed, W. P. Eaton, and H. Fiske.

The following were appointed as delegates to attend the convention to be held at Worcester on the 2d of July next: Messrs. Calvin Goddard, Nathaniel Shipman, D. Ripley, Wm. P. Greene, Jno. L. Buswell, Chas. P. Huntington, Elisha Tracy, Sam'l. Tyler, John Breed, Asa Child, Wm. C. Gilman, J. A. Rockwell, Thos. Robinson, C. W. Rockwell, Wm. Williams, Jr. Jed. Huntington, Geo. L. Perkins, Amos H. Hubbard, J. G. W. Trumbull, J. W. Kinney, Jas. L. Ripley, Leonard Perkins, Charles Coit, Jno. T. Adams, Edward Whiting, Samuel Story, Gurdon Chapman, Jos. Backus, E. C. Chapman, Jos. Spalding, Andrew J. Clark, L. F. S. Foster, Erastus Coit, Geo. B. Ripley, W. P. Eaton, Simeon Thomas, Gurdon A. Jones, and Gurdon Pendleton.

Colonel Long has been appointed by the Secretary of War to survey the route of a railroad from Portland to the Canada Line. Lord Aylmer, Governor of Lower Canada, expresses himself highly in favor of the project of connecting that province with Maine, by the proposed railroad, and has appointed a gentleman to survey the route in connection with Col. Long.

[From the London Mechanics' Magazine.]  
*Morgan's Paddle-Wheel in its Latest and  
 Most Approved Form.*

The paddle-wheel now commonly known by the name of *Morgan's*, was originally invented by Mr. Elijah Galloway, and patented by him in 1829. The first trial made of it was on board a steam vessel, of which Mr. Wm. Morgan was the principal and acting owner, who was so much pleased with its performance that he became by purchase the proprietor of the patent. The Commissioners of the Admiralty were afterwards induced to order that a pair of these wheels should be fitted by Mr. Morgan to H. M.'s steam vessel *Confiance*. On the 9th of September, 1830, Commodore Warren, accompanied by Mr. Lang, of the Dock-yard, Woolwich, proceeded down the Thames in the *Confiance*, on an official trial of the wheels. The Report made by the Commodore to the Admiralty, was, "That with 23½ revolutions of the engine, (24 to 25 revolutions being their regulated speed,) the vessel had improved in speed (as far as could be collected from so limited a trial) from 1 to 1½ knot an hour; that although the floats, in leaving at such rapidity, must necessarily disturb the water, so perfectly were the ill effects of the back-water obviated, that when the vessel was going at her utmost speed, he had caused a wherry, which was being towed astern, to be hauled up along-side, and close up to the paddle-box, without the slightest inconvenience, or without her shipping even a spray; and finally, that the previous vibration suffered from the action of the wheels was so reduced as to be barely sensible on the paddle-box itself."

On the 11th of September, Admiral Sir Geo. Cockburn embarked on board H. M.'s steam yacht, the *Lightning*, to

proceed to the channel on an experimental cruise, H. M.'s steam vessels, the *Confiance* and *Echo*, being ordered to proceed in company. These three vessels were all fitted with engines of equal power, namely, 100-horse power each. The *Lightning*, however, having been originally laid down for a steamer, is fifteen feet longer, three feet narrower, and draws nearly two feet less water than either of the other two vessels, and from her superior swiftness and other qualities, was selected for H. M.'s steam yacht. The *Confiance* and *Echo* are in every respect sister vessels, were laid down from the same drawing, and were originally intended for gun brigs. The three vessels were started abreast by signal from the Vice-Admiral. The improvement in the *Confiance* was evident from the first starting, as she was enabled to keep even pace with the *Lightning*, whenever the revolutions of her engines reached 23, and to pass her whenever they exceeded that velocity. In this way they ran together to the Downs, where they anchored. The *Echo*, although previously of equal speed with the *Confiance*, fell back so rapidly, that at the expiration of the first hour, the Vice-Admiral made her signal to return, she being then two long miles astern. Hitherto the weather had been calm, and the water smooth.

On the 12th September the two vessels, *Lightning* and *Confiance*, were ordered to weigh, and to stand to the S. W., wind fresh, and sea rough ahead, circumstances in which the previous superiority of the *Lightning* had been most remarkable. The lead was now, however, very decidedly taken by the *Confiance*, whose gain over her competitor, under these circumstances, was about a half knot on seven miles per hour, that being the speed at which the *Lightning* was driven.

The following day the *Confiance* was ordered to New-Haven, and accordingly started at 8½ A. M., wind strong, and heavy sea from W. S. W. At 4 P. M., off Beachy Head, she passed H. M.'s steamer *Carron*, (which vessel had left the Downs five hours before her,) making the best of her way to Plymouth on earthe behavior of the wheels, stated "that vice. Having performed the service required of her, the *Confiance* was ordered back to Woolwich, where she anchored September 14. The commander, Lieut. Belson, having been ordered to report on the improvement in the vessel's speed was proportionately greater in a sea-way than in smooth water; that the action of the wheels was no way impeded by that of the waves, since the variation in the velocity of the engines did not exceed one to two revolutions; that the vessel's way was never stopped; and that there was no sensible increase of vibration on the paddle-boxes during the gale, over the very slight tremor felt in smooth water."

The commanders of H. M.'s steam vessels *Carron* and *Confiance* having received orders to proceed on a further experimental cruise to Cape Clear, and thence round the Fastnet Rock back to Plymouth, these vessels, similar in every respect, excepting in their wheels, started from the Breakwater by signal from the Port-Admiral on the 1st of October, wind strong, and a rough sea from the W. S. W. In five hours the *Carron* was hulled down astern. The *Confiance* anchored at Haroaze on the 4th of October, and the *Carron* on the 5th. The *Confiance* performed in 54 hours the distance which occupied the sister vessel, the *Carron*, 84 hours in running. Independently of the great saving of fuel effected, namely, 10 bushels per hour on the time saved in running the same distance as the sister

vessel, viz., 30 hours, other advantages have been secured by the modification in question, as may be collected from the reports officially made, jointly and separately, by Lieut. Potbury, then commanding the *Confiance*, and Lieut. Lapidge, in command of the *Carron*. In reply to the questions put to them by the Admiral commanding at Plymouth, in virtue of directions from the Commissioners of the Admiralty, these officers stated, "that the *Confiance* had, on a comparison of their respective logs, gained by the alteration in her wheels an increase of speed of 2 knots on 7 in smooth water, and 2½ knots on 4 to 4½ knots in rough weather; that the action of the paddles did not bring up the engines or retard their velocity in a head sea; that in rolling, their action assisted in righting the vessel, and that the wear and strain, as well on the vessel as on the engines, was materially reduced."

The superiority of the new wheel was considered to be so decisively established by these trials with the *Confiance*, that Mr. Morgan was subsequently employed by the Lords of the Admiralty to apply it to the other government steamers—the *Flamer*, the *Firebrand*, the *Columbia*, the *Spitfire*, and the *Lightning*. We extract the following particulars respecting the performances of these vessels, from the evidence lately given on the subject by Mr. Morgan, before the select committee on Steam Navigation to India, and from the official reports of their respective commanders to the Admiralty:

The *Flamer* displaces 590 tons (including 120 for engines, 140 for coals, and 30 for stores); her cylinders are of 42 inches diameter, and 4 feet stroke; and her wheels 18 feet in diameter, and 5 feet 6 inches wide. When the vessel is deep, her wheels revolve from 14 to 20 times per minute in rough water, and 26 times per minute in smooth. When the vessel is light, the speed of the wheels is increased from 18 to 22 revolutions in rough water, and from 26 to 28½ in smooth. The commander of the *Flamer*, Lieut. Bastard, in report of 23d January, 1834, says of the wheels, "in six weeks of most tempestuous weather, found them to act remarkably well, without even a single float being shifted."

The *Firebrand* was built on the same lines, and is of the same scantlings, as the *Flamer*, with the exception of having 9 inches more depth; she had also originally 20 horses more steam power. Her paddle-wheels were at first of the common sort, and then her velocity was three quarters of a mile less than that of the sister vessel, with wheels of Mr. Morgan's construction. But since the *Firebrand* has been supplied with Morgan's wheels, she has attained nearly the same speed as the *Flamer*; and this though her old engines have been replaced by a new pair, of no greater power than those of the *Flamer*—namely, two sixty's.

The *Columbia*, as originally constructed, displaced altogether 480 tons; her engines were of 120-horse power, and her wheels (of the common sort) 16 feet

6 inches in diameter, and 8 feet wide. Her performance was then from 14 to 16 revolutions per minute, when she was deep; and from 24 to 26 revolutions per minute when light; the weather in both cases favorable. Being afterwards supplied with a pair of Morgan's wheels, 17 feet in diameter, and 5 feet 2 inches wide, with a new pair of engines of only 100-horse power, and with 30 tons more of coal, making her total displacement 40 tons more than before, the wheels performed, in similar weather, from 20 to 25 revolutions per minute when she was deep, and from 26½ to 28 when light. "She obtains," says Lieut. Ede, her commander, "greater speed than with the superior power she had before and the old wheel. The new wheels save the engines."

The *Spitfire*, with engines, coals, &c. displaces 715 tons; her engines are of 140-horse power, and her wheels 20 feet in diameter, and 4 feet 9 inches wide. Number of revolutions when light, and in smooth water, 23 per minute. Lieutenant Kennedy, the commander of the *Spitfire*, in his report, of date 3d December, 1834, says, "Had put to sea with the wheels in weather in which it would have been madness to attempt in any vessel with the common wheel, but that she had gone over it 4½ knots an hour, without scarcely feeling the wheels moved. With the old wheels would have been

forced to put back, but had with these (Morgan's) made his passage from Gibraltar to Falmouth against a heavy gale nearly the whole way."

The *Lightning* has been before described. Her commander, Mr. Allen, in reporting on the effect produced on her rate of going, by the adoption of Mr. Morgan's wheels, says that "the speed was much improved in heavy weather," and "the vibration nearly done away with."

The wheels of the *Medea*, the largest war-steamer yet constructed by the British Government, the *Tartarus*, and *Blazer*, are also on Mr. Morgan's plan.

During the last summer, Mr. Morgan was employed to fit a pair of his wheels to his Sardinian Majesty's steam-vessel *Gulnare*; and it is from these wheels, the latest (we believe) manufactured by Mr. M., that the drawings have been made.

The wheel, as now constructed by Mr. M., embraces a good many improvements on the original design of Mr. E. Gallo-way. The most prominent difference is an increase in the number of radial arms and paddles, from four to nine. To show how much the wheel has gained from the successive modifications which experience has suggested, we here annex an engraving and description of it in its original form, as given by Mr. Galloway himself, in his "History and Progress of the Steam-Engine":

"The object of this wheel is to provide a remedy for the loss of power, and other inconveniences arising from the oblique position in which the float-boards of the common paddle-wheels enter and leave the water. This the inventor purposes to effect by causing each float-board to turn, or rather vibrate, on an axis at its edge next the centre of the paddle-

wheel, through the medium of projecting levers, firmly fixed to the float-boards, at their axis of motion, and connecting rods proceeding from the extremities of these levers to the extremity of a fixed crank, adjustable at a given distance from the centre of motion of the paddle-wheel, which consists of four radiating arms, connected at their extremities by strength-

ening braces; *b b* represent the four arms of the wheel, and *e e* the strengthening braces; *c c* are the paddles, firmly fixed to which are the levers *d d*, forming angles of about 120 degrees with each other, and turning together on axes at *e e*; *f* represents the water-line; *g* is the crank, fixed centrally to the axis of the wheel, but so as not to revolve with it; this crank is alterable at pleasure, by means of a set screw, which causes the paddles, through the medium of the connecting rods *i i*, to take such an angle with the water-line as may be deemed most desirable for propelling; the rods *i*, however, are connected to a revolving collar on the crank, which allows of free rotary motion, while it draws the paddles uniformly into the positions shown in the engraving, when the arm of the crank is set in a horizontal position, as represented. The dotted lines show the position the paddles assume in the intermediate parts of their revolution, or the relative position they would take if there were eight paddles attached to the wheel."

**AVERY'S ROTARY ENGINE** proves, we are much pleased to be able to state, (as we do on good authority,) to be peculiarly adapted to milling purposes. The following statement, which we take from the *Syracuse Constitutionalist*, confirms fully the anticipations of those who have been familiar with its operations for more than two years; and other instances might be cited, if necessary—one especially, at the south, in which it performs to the entire satisfaction of those using it. Its simplicity, however, and entire safety, cause many to doubt its power, until they witness its performances—which, in some instances, may be said to be truly astonishing. As with many, seeing only is believing, we hope soon to be able to exhibit a sample of its performances in this office, attached to the press on which this Journal is printed, that will satisfy all those who may doubt. When it is in operation, due notice will be given.

"An experiment has been made in Mr. N. Felt's sawmill, in Cicero, with one of Wm. Avery's patent Rotary Engines, manufactured in this village by E. Lynds & Son, which has satisfactorily proved (if any further proof was indeed necessary) its superiority over any other now in use. Mr. F. some four years since procured a High Pressure Piston Engine for the purpose of propelling the machinery of his sawmill, but has never been able to produce any satisfactory results, and therefore discarded it entirely. At the suggestion of the Messrs. Lynds, he was induced to make an experiment with one of the Rotary Engines—one of which was accordingly attached to the same boiler used for the other engine, and put in operation. The experiment proved eminently successful, and those who witnessed its performances are well satisfied of its great utility in propelling machinery of every description, and also of its superiority to the engines in common use.

"The following statement of Mr. Lewis, who is deemed one of the first millwrights and mechanics in the state, sustained as it

is by the opinions of a number of others well qualified to judge, will go to show in what estimation the invention of Mr. Avery is held by those who have experience in such matters:

"To the Public.—Having been requested by Messrs. Elam Lynds & Son, to examine a Rotary Steam Engine, manufactured at their foundry, (of Wm. Avery's invention,) now in Mr. N. Felt's Sawmill, and in which I am informed they have had a common Piston Engine, with which they were unable to operate their mill successfully,—being much pleased with the operation of the Rotary Engine, although it was laboring under great disadvantages, I embrace this opportunity of saying to the public, that I am satisfied that there is abundant power to operate a mill successfully, and I consider them far preferable to any other Steam Engine now in use for milling purposes. "ISAAC LEWIS.

"Syracuse, April 20, 1835.

"We were present at the above exhibition of the power of the Rotary Steam Engine, and fully concur with Mr. Lewis in his statement, from what we saw of the operation of the Engine, and from our confidence in him as a millwright and a practical mechanic.

#### FOR THE NEW-YORK AMERICAN.

The 11th inst. is the day fixed upon by the Legislature for adjournment. In the confusion arising from the multiplicity of matters which will be pressed forward with the ardor of private interest, it is to be feared that matters of great public moment may be neglected. Are the citizens of New-York aware that they are deeply interested in the speedy accomplishment of a continuous Railroad line, reaching from the tide waters of the Hudson to the great navigable waters of the western world? And that this is on the eve of accomplishment, provided the Legislature can be induced to afford the necessary facilities to the action of private enterprise.

The Railroad from Albany to Schenectady has been in operation some years. The Schenectady and Utica Railroad will be completed so as to accommodate the *Summer travel* of 1836. The enterprising stockholders of the Syracuse and Auburn Road have put Engineers upon that line, who are followed by their agent ready to make contracts, with the intention to have their road in operation *as soon as the road shall be finished to Utica*, and the road from Rochester to Batavia is far advanced. It requires then to complete a Railroad throughfare from the Hudson River to Lake Erie, only the connecting link from Utica to Syracuse, about fifty miles, from Auburn to Rochester about sixty miles, and from Batavia or Utica to Buffalo about forty miles.

Applications are now pending for Charters to construct these several connecting links; companies are ready to take the stock, and proceed with the work immediately; and if they are allowed to proceed, there is every reason to believe, that this whole line will be completed and in operation within two years. The most important of these connecting links, are the two from Auburn and Rochester, and from Batavia to Buffalo—the long level of the Canal, without a lock between Utica and Syracuse, will, for a time, be a good substitute. Can New Yorkers fail to see the importance to this city, of opening *without delay*, this avenue, and using it, till more favorable State councils shall yield to what we consider the *just rights* of the south-western counties and the claims of this city?—

Should there not be a loud call upon the attention of the Legislature to this matter, during the few remaining days of the session? X.

**CANAL TOLLS.**—There has been received for canal tolls, at the Albany collector's office, from the 15th to the 30th of April, both days inclusive, the sum of \$42,015 65. This is by far the greatest amount received for tolls during the month of April in any one year since the canals were constructed. It exceeds last year, when the canal opened 2 days later, by the sum of \$22,000; and it exceeds 1833, by the sum of nearly \$18,000, when the tolls on merchandise were 25 per cent. higher; although in 1833 the canal opened several days later than in 1835.

The Erie canal was navigable in its whole extent on the 15th of April; and although the season was unusually backward and unfavorable, the navigation has been maintained without interruption. There will be no hesitation, after this experiment, about the practicability of opening the canal as early as the middle of April.

The N. Y. American has been filled with alarms about the diversion of the trade of the west, and its editor, at times, has seemed almost ready to exclaim with Mr. Ewing, "the canal is a solitude." To all who desire to know the truth on this subject, we offer the single fact, that there has passed up the Erie canal, during the month of April, 1835, at least twice as much merchandise as passed up during the same month in either of the three preceding years. Is this evidence that the early trade has been diverted from the canal?

The above article from the Albany Argus, has been excluded for two or three days past by the press of Foreign news. We now insert it, with all the satisfaction at the prosperity of the Erie canal, which it records, that can possibly be felt, by the Argus, or any party, directly and personally interested—which we are not—in the region to which the canal, dispenses, in its course, such substantial benefits.

But the Albany Argus seems incapable, or unwilling, to look at the question of public improvement, in any but one light—or to believe, that off, or beyond, the line of the Erie Canal, and the Railroads parallel with, or following, its course—there can be any just claim for legislative aid and countenance.

According to our view, this is neither honest nor patriotic. We think—and in forming our opinion in this matter, we are as absolutely without any personal interest, as in reference to the region affected by the Erie canal—that no man who seriously means the good of the State, and is not biased by conflicting—or what he may suppose to be a conflicting—interest, can look at what is doing in Pennsylvania towards securing the trade of the Mississippi Valley, and at the unquestionable claims of our south-western counties, to some aid from the State, towards enabling them to compete with these efforts of Pennsylvania—without feeling, that the rejection by the present Assembly of the application of the New York and Erie Railroad Company, was, to those counties a wrong and an injury, and a grave error, as a mere matter of State interest and pride.

It was a want of just patriotism then—restricting on this occasion the use of that word to a paramount regard for one's own State,—not to have lent a willing and liberal hand towards the construction of the Erie Railroad.

\* \* \* \* \*  
As to the amount of tolls on the Canal in April, it proves nothing in regard to the main question, that of the early spring supply to the far West. The truth is, that the creative influence of the Canal, upon the Country through which it passes, has been such, that it can scarcely suffice for the transportation of the merchandise needed, and the produce raised, within the Counties contiguous to it. The recent vote for doubling the Canal may be

adduced in proof. It is the home demand, we venture to say, and not that for other States, which has pressed forward so rapidly. The Lake too at Buffalo was yet fast—and likely to remain fast, at the latest dates, with ice—while at Dunkirk and Portland, the proposed terminations of the Erie Road, the navigation has been open for weeks past. Moreover, as to the fact of much early trade to the Mississippi valley having been diverted from this city to Philadelphia—and through Philadelphia—we speak from personal knowledge.

With this fact, then, in view—with the spirited efforts we are daily witnessing on the part of Pennsylvania, to assure her superiority over us as carriers of the trade of the West—and with the knowledge of how difficult it is to change the channels of trade, when once worn deep—we repeat, that we consider the rejection of the prayer of the *New York and Erie Railroad Co.* a mistake in policy, and an injury and wrong to this city, and to the great Counties of the Southwest.

**A REBUKE NOT UNMERITED.**—The Philadelphia Inquirer of yesterday has this paragraph.

Within the last fortnight, the stocks of the Pennsylvania and Ohio Canal; of the Sandusky and Beaver Canal; and of the Portsmouth and Harrisburg Rail Road, all works of internal improvement, and designed to facilitate the intercourse between this city and the great West, have been readily disposed of in this city; and our capitalists are ready for any other movement calculated to advance the prosperity of Philadelphia. Contrast this commendable spirit of enterprise with that which has been manifested by the New Yorkers, in the case of the Erie Railroad, and no Philadelphian can fail to cherish a just and laudable degree of pride for the spirit and liberality of our merchants and capitalists generally.

**Important and interesting Mission.**—The Senate of the United States, at its last session, passed a resolution, requesting the President to consider of the expediency of entering into negotiations with the South American States, for the purpose of securing for our commerce and people, a safe passage across the Isthmus, from the Atlantic to the Pacific Ocean. In compliance with this recommendation of the Senate, we understand, the President has appointed Colonel Charles Biddle, of Tennessee, to conduct the negotiation, and that he is about to visit the Southern Continent, in prosecution of the objects in view.—[Pennsylvanian.]

**On Providence.**

*From the Sonnets of Millicaja.*

"Qual madre i figli con pietoso affetto!"

Even as a mother o'er her children bending  
Years with maternal love: her fond embraces  
And gentle kiss to each in turn extending,  
One at her feet, one on her knees, she places,  
And from their eyes, and voice, and speaking faces,  
Their various wants and wishes comprehending,  
To one a look, to one a word addresses,  
Even with her frown, a mother's fondness blinding.  
So o'er us watches Providence on high,  
And hope to us, and help to others lends,  
And yields alike to all an open ear,  
And when she seems her favors to deny,  
She for our prayers alone the boon suspends,  
Or seeming to deny, she grants the prayer.

**THE MICHIGAN WAR.**—An extra from the office of the Buffalo Whig, dated Monday last, furnishes the following intelligence, copied from the Detroit Free Press of the 29th of April.

We stop the press to announce the intelligence that the first blow has been struck in the Border War between Michigan and Ohio. In violation of his oath to support the Constitution of the United States, and of the sacred obligations of his State to the Union; trampling upon the laws of that Union, and upon both its rights and the rights of Michigan, the Governor of Ohio, in pursuance of an unconstitutional act of the Legislature of that State, and regardless of the admonitions he has received from the General Government, perseveres in his efforts to extend the jurisdiction of Ohio over a part of the Territory of Michigan. For that purpose, early last week, he sent the Commissioners of that state, escorted by an armed force, to the west end of our Territory, adjoining Indiana, to retrace and run the boundary line through Michigan, illegally claimed by Ohio.

A penal law of Michigan, which is a law of the United States until repealed by Congress, provides for the arrest and punishment of any person accepting or exercising within our Territory, any office or authority, unless derived from the government of Michigan, or of the United States. This law has been pronounced valid by the Attorney General of the United States.

In virtue of this act, information having been received on Saturday last, that the Ohio Commissioners, protected by an armed escort, were engaged in running the boundary line through Hillsdale and Lenawee counties, and affidavit of the facts having been made before Charles Hewitt, Esq., of Tecumseh, that magistrate issued his warrant for the apprehension of Patterson, Taylor and Seely, the aforesaid Commissioners, and other persons engaged in violating the laws of the Territory. With this warrant, the Sheriff of Lenawee, summoning a posse of thirty or forty persons, the most respectable citizens of that county, proceeded on Saturday evening to Adrian, and on Sunday morning directed his deputies to go on with the posse, about fourteen miles due south of that place, where they understood the trespassers and violators of our laws were then probably stationed.

With the knowledge that those Ohio people were armed, it became an imperative duty to arm our posse. On arriving near the house of Phillips, 7 miles within the Michigan line, they found nine or ten armed men, ascertained to be a portion of the Ohio party. Two of the deputy sheriffs, leaving the posse thirty yards distant, immediately proceeded towards the house, advised the party that they had a warrant for their arrest, and demanded their surrender.

The Ohio men refused to surrender, raised and levelled their arms at the Sheriffs, and threatened to shoot them. Not daunted, those officers urged forward, and came within a few steps of the enemy. It became by this time evident, that they meant to run; and orders were given to fire over their heads, and bring them to, if they did run. As was expected, they took to their heels, but were chased, and captured. They had been instructed and they had threatened not to be taken alive.—Col. Hawkins, the Ohio Surveyor, and seven armed persons, nine in all, were made prisoners, and brought to Tecumseh for examination on Monday morning.

The Commissioners happened to be at another house, about 200 yards from the house of Phillips, at the time the above persons were captured.—They ran into the woods, were pursued, but could not be overtaken. Gen. Taylor, one of them, made a hasty retreat, to Maumee, about 30 miles, never stopping until he arrived there. The other Commissioners subsequently followed him.

The Governor of Ohio, who has a force of about 500 troops collected at Maumee, has issued orders for the raising and marching of 10,000 men to that point, declaring that he will never recross the Maumee Swamp until he runs the boundary line and extends the jurisdiction of Ohio over that part of our territory claimed by her. All this he proclaims he will effect, in despite of Michigan and any assistance which the U. States may afford her. If this threat should be attempted to be executed; if the Governor of Ohio should invade Michigan with an army, he and they will commit treason against the U. States, and be dealt with accordingly. One thing, at least is certain: Michigan will

never submit to be invaded, nor to have the jurisdiction of Ohio extended over any part of her territory. We presume that an invasion will be promptly repelled, not by a posse, but by all the force that can be raised. Our militia law amply provides for the emergency.

We have no doubt, however, that the President, as soon as informed of the present state of things, will promptly interpose with effect against Ohio. The authorities of that State have inflicted a blow upon the Union of these States far more dangerous and destructive to it, than the Nullifiers of South Carolina aimed at it. Indeed, we are told that Gov. Lucas admits that his conduct amounts to Nullification.

[FOR THE NEW YORK AMERICAN.]

**Weyer's Cave.**

I hope I shall be pardoned for encroaching upon your territory of Politics and Internal improvements, and making a few remarks upon the great and magnificent wonder of nature above mentioned. It cannot be said too often, that we Americans, are sadly insensible to the beauties which nature has scattered over this noble continent. It is a reproach which ought to be wiped away from amongst us, and to that end our sense of shame cannot be mortified too often, or too severely. The means of travelling are so greatly improved, our national character is becoming so exalted, that it is a perfect outrage, that our Irvings and Hoffmans should be able to present to our eyes, a terra incognita within our borders. Americans should know more about their own country from personal observation, and instead of visiting Europe almost exclusively, to marvel at rivers and mountains, should bring to light the almost hidden treasures of nature, which have been lavished upon their native land.

Weyer's Cave is a natural curiosity which takes rank with the wonders of the universe—with the Falls of Niagara, with the Natural Bridge, and the far famed Grotto of Antiparos—and yet, out of Virginia, it is hardly known to exist. Those who have never seen it, can hardly form a conjecture of its sombre grandeur and splendor. Its silent chambers, buried many feet beneath the surface of the earth, extend nearly half a mile in length. The light of day never penetrates these solemn caverns—the "blessed sun" never reveals the treasures of nature which lie entombed within them. But when torch-light breaks the gloom which overhangs them, the brilliancy and grandeur of the scene is beyond all conception. The bright star, in a hundred different shapes, gleams all around, while the stupendous formations, and the grotesque imagery which meet the eye, make one doubt if he have not passed into a new state of being. The mind is carried back to the distant period when this silent labor of nature began—it contemplates the ages and ages which have rolled away, the empires which have fallen, while the little water-drop has silently and surely performed its office, regardless of the conflicts of nations, and heedless of the angry elements. But a newspaper is not the place to indulge in these reflections. I will make a few matter-of-fact suggestions, and then conclude this notice.

Weyer's Cave is situated in Augusta County, Virginia, in the Valley of the Shenandoah, and about seven miles from the Blue Ridge. It is perfectly accessible, and may be conveniently taken on the way to the Natural Bridge and the Sulphur Springs. The communication from this and the other Northern cities to Fredericksburg, is nearly the whole distance by steam—thence to Charlottesville the roads are very good. The Cave is only about 32 miles from the latter town, and the route one of the most picturesque in the whole state. With such facilities, our travelling community should not delay to make a visit to Weyer's Cave, and those who really love to look upon the works of nature, will not fail to go there. As a further inducement, I would remark, that the proprietor of the Cave, and all who are connected with it, are among the most intelligent and hospitable persons within the knowledge of

A TRAVELLER.

## NEW-YORK AMERICAN.

MAY 2-8, 1835.

## LITERARY NOTICES.

**HISTORY OF NEW-YORK.** 2 vols. By *Uncle Philip*. Comprising vols. XXIII. and IV. of the *Boys' and Girls' Family Library*. New-York—HARPER AND BROTHERS.—We repeat, on this occasion, what we have more than once said before in reference to Uncle Philip's admirable contributions to the cause of education, that though professing to be addressed to young minds, his books will, for the most part, afford instruction and amusement, to all of more advanced years, who have not had time, or opportunity, for much study.

In the volume now before us, the History of our own State is plainly and agreeably written—beginning with the discovery by Hudson, and brought down to the revolution.

We published, some days ago, and warmly commended the object of, a law recently passed by our Legislature, authorizing the inhabitants of school districts to levy a small annual tax for the purchase of a District Library. These books of Uncle Philip's are peculiarly of a character fitted for such libraries; for they are pure in sentiment, correct in style, and accurate in information.

We commend them, accordingly, to the attention of the Trustees of the School Districts, and of parents and instructors generally.

**THE RISE AND PROGRESS OF RELIGION IN THE SOUL.**—In a Series of Practical Addresses, by P. DODDRIDGE, D.D., with an Introductory Essay by JOHN FOSTER, author of *Essays on Decision of Character*, &c. 1. vol. New York. D. APPLETON & Co.

This is a republication of an old and much approved book, written with a studious regard to plainness of style and statement, so as to be level to all capacities.

Its bulk is nearly doubled by the preliminary essay of Mr. Foster, written in his accustomed style of vigorous eloquence.

**JOURNAL**, by FRANCES ANNE BUTLER. 2 vols. Philadelphia: CAREY, LEA, AND BLANCHARD.—The long note of preparation which has preceded the appearance of this Journal, and the stolen fragments from it, which appeared originally in a Boston paper, and were thence transferred to many others, have combined to excite curiosity and interest to a degree, that we cannot but consider—without meaning to be ungallant—ridiculous. This nation—this great nation, as we are wont to consider ourselves—is on tiptoe, so to speak, to know what is thought and said of them, by a very clever young lady, whom necessity, and not her will or choice, made an actress.

The hour of suspense is past—the curtain is lifted, and without preface or explanation, “the Journal” is before the world. That it is a faithful transcript, so far as it goes, of the record made at the time, seems to us clear, from internal evidence.—How far the facts omitted—and to judge from the numerous asterisks, there are many such—might qualify what is retained, it concerns us not to inquire; for the book must be judged by what it is, not by what any one may choose to fancy it would have been, if all had been told.

Adopting this standard then, we may say, that “the Journal” is sprightly, amusing, careless, often vulgar, occasionally flippant—and then again fervid with taste, eloquence, and po-

etry: the opinions, incidentally expressed, concerning the habits and manners of this country, the tone of its society, the nature and tendency of its political institutions, are such as every one is, and should be, at full liberty to express, if they are entertained; and by the expression of which, we cannot fail to profit—if reason rather than vanity be our counsellor.

There is undoubtedly much in these pages that will shock and mortify individuals, and over sensitive people—very often because of the disagreeable fidelity and truth of the representations given—at other times because of the obvious injustice of these representations. Yet after all—at best and at worst—what does it all amount to? Simply this, that a young, well educated and clever woman, who had been idolized in her own country, and intoxicated by the unstinted breath of popular applause lavished on her theatrical performances—accustomed to a particular mode of life, to certain conventional notions of refinement—and coming among us with all the feelings of European superiority—a sentiment by no means confined to our visitors from England—is sometimes shocked by the display of of pretensions that seem to her unfounded and ridiculous, at others, is amused at the sensitiveness which she sees manifested, as to how such a “clever girl” as herself will look upon Americans—and that she describes with a sharp and biting pen the emotions she experiences.—Is there any bar to such freedom of opinion? Is there any breach of hospitality—so long as she does not individualize her pictures—in such a record of first impressions? above all, is there any want of gratitude in so doing? Surely not. On this score of gratitude, by-the-by, there is a capital common sense note in the second volume of the Journal, which sets that matter in its true light. The idea that “gratitude” should be felt by actors, because their performances have been attended by large audiences, is very properly scouted—the whole thing is put upon the footing of a *quid pro quo*: the audience attend because they think the attraction of the performance worth the dollar it costs—and the actors play because they want the dollar of the spectator. When the curtain drops the account is balanced, and both parties are even.

Three times out of four this reasoning is equally true, as applied to the intercourse in private life, to which public personages—whether actors on the real, or the mimic, stage of life—are admitted in this country. They are sought as lions, and quite as much for the gratification of the entertainer's vanity, or love of novelty, as for the sake of obliging strangers. This cannot escape the notice of those so honored!—and the obligation therefore conferred by such advances, is balanced by the *éclat*, which they are made to feel, their presence at a fête will impart.

These remarks are not, it will be perceived, at all applicable to that sort of intercourse with strangers which results from a real admiration of merit and talent—from sympathy with, or respect for, regular avocations or pursuits, or from kindred genius and feeling—and accordingly it will be found, we think, throughout this Journal, that, although the necessarily heartless and selfish characteristics of general society, are touched off with a sharp hand, justice is done to the sincere and cordial greetings of more private circles.

Upon the whole, the only party likely to suffer by this publication, is the writer, for it certainly is beneath her reputation as a literary person.

**SPEECHES AND FORENSIC ARGUMENTS**—by DAN WEBSTER, 2 vols.; Boston, PARSONS, MARTIN & Co.—For sale here by D. APPLETON & Co.—We took occasion some days ago, to quote some of the preliminary remarks in the second volume of these speeches, in which justice was done to the talents and character of Mr. Webster. We had not then seen the publication, which however is now before us, and we recommend it to all readers, as one of enduring value.

We make an extract—not for its novelty—but because, although published before, it cannot be too often referred to, as illustrating the highest traits of Mr. Webster's character as a patriot, and talents as an orator.

It is the conclusion of his celebrated reply to Mr. Hayne, in the Senate of the United States.

Mr. President, I have thus stated the reasons of my dissent to the doctrines which have been advanced and maintained. I am conscious of having detained you and the Senate much too long. I was drawn into the debate, with no previous deliberation such as is suited to the discussion of so grave and important a subject. But it is a subject of which my heart is full, and I have not been willing to suppress the utterance of its spontaneous sentiments. I cannot, even now, persuade myself to relinquish it, without expressing, once more, my deep conviction, that, since it respects nothing less than the union of the States, it is of most vital and essential importance to the public happiness. I profess, sir, in my career, hitherto, to have kept steadily in view the prosperity and honor of the whole country, and the preservation of our federal union. It is to that union we owe our safety at home, and our consideration and dignity abroad. It is to that union we are chiefly indebted for whatever makes us most proud of our country. That union we reached only by the discipline of our virtues in the severe school of adversity. It had its origin in the necessities of disordered finance, prostrate commerce, and ruined credit. Under its benign influences, these great interests immediately awoke, as from the dead, and sprang forth with newness of life. Every year of its duration has teemed with fresh proofs of its utility and its blessings; and, although our territory has stretched out wider and wider, and our population spread farther and farther, they have not outrun its protection or its benefits. It has been to us all a copious fountain of national, social, and personal happiness. I have not allowed myself, sir, to look beyond the union, to see what might lie hidden in the dark recess behind. I have not coolly weighed the chances of preserving liberty when the bonds that unite us together shall be broken asunder. I have not accustomed myself to hang over the precipices of disunion, to see whether, with my short sight, I can fathom the depth of the abyss below; nor could I regard him as a safe counsellor in the affairs of this government, whose thoughts should be mainly bent on considering, not how the union should be best preserved, but how tolerable might be the condition of the people when it shall be broken up and destroyed. While the union lasts, we have high, exciting, gratifying prospects spread out before us, for us and our children. Beyond that I seek not to penetrate the veil. God grant that, in my day, at least, that curtain may not rise. God grant, that on my vision never may be opened what lies behind. When my eyes shall be turned to behold, for the last time, the sun in heaven, may I not see him shining on the broken and dishonored fragments of a once glorious union; on states dismembered, discordant, belligerent; on a land rent with civil feuds, or drenched, it may be, in fraternal blood! Let their last feeble and lingering glance, rather behold the gorgeous ensign of the republic, now known and honored throughout the earth, still full high advanced, its arms and trophies streaming in their original lustre, not a stripe erased or polluted, nor a single star obscured—bearing for its motto, no such miserable interrogatory, as *What is all this worth?* Nor those other words of delusion and folly, *Liberty first, and Union afterwards*—but everywhere, spread all over, the characters of living light, blazing on all its ample folds, as they float over the sea and over the land, and in every wind under the whole heavens, that other sentiment, dear to every true American heart—*Liberty and Union, now and forever, one and inseparable!*

ON THE IMPROVEMENT OF SOCIETY BY THE DIFFUSION OF KNOWLEDGE; vol. IV. OF DICK'S WORKS—Philadelphia, KEY & BIDDLE.

We have now four volumes completed of the writings of Thomas Dick—all tending to the same great end, the improvement of the moral and intellectual condition of the human race.

The volume now before us is specially designed to illustrate the benefits which would result "from a more general dissemination of rational and scientific information" among all classes. It is well executed and amusingly—a great matter where instruction is concerned.

One great result that may be hoped for, from a more enlightened state of the public mind is thus set forth.

A general diffusion of knowledge would be one general mean of promoting union in the Christian Church.

It is a lamentable fact, that throughout the whole world, there is no system of religion the votaries of which are subdivided into so many sectaries as those who profess an adherence to the Christian faith. Within the limits of Great Britain there are perhaps not much fewer than a hundred different denominations of Christians belonging to the Protestant Church. We have Calvinists, Arminians, Baxterians, Antinomians, Arians, and Unitarians, Episcopalians, Presbyterians, Methodists, Baptists, and Independents,—Seceders, Brownists, Sandemanians, Quakers, Moravians, Swedenborgians, Millenarians, Sabatarians, Universalists, Sublapsarians, Supralapsarians, Dunkers, Kilhamites, Shakers, &c. Of some of these there are several subdivisions. Thus, there are three or four denominations of Seceders, four or five of Baptists, three or four of Methodists, and two or three of Glasites or Sandemanians. Most of these denominations recognise the leading truths of divine revelation,—the natural and moral attributes of the Deity,—the fall of man,—the necessity of a Saviour,—the incarnation of Christ,—the indispensable duty of faith in him for the remission of sins,—the necessity of regeneration, and of holiness in principle and practice,—the obligation of the moral law,—the doctrine of a resurrection from the dead, and of a future state of rewards and punishments,—in short, every thing by which Christianity is distinguished from Mohammedanism, pagan idolatry, and all the other systems of religion that prevail in the world. Yet, while agreeing in the leading doctrines of the Christian faith, they continue in a state of separation from each other, as if they had no common bond of union, and as rival sects, are too frequently in a state of alienation, and even of open hostility. The points in which they differ are frequently so minute as to be incapable of being accurately defined, or rendered palpable to an impartial inquirer. Where the difference is most apparent, it consists chiefly in a diversity of opinion respecting such questions as the following: Whether the election of man to eternal life be absolute or conditional,—whether Christ died for the sins of the whole world, or only for a limited number,—whether there be a gradation or an equality among the ministers of the Christian church,—whether every particular society of Christians has power to regulate its own affairs, or ought to be in subjection to higher courts of judicature,—whether the ordinance of the Lord's Supper should be received in the posture of sitting or kneeling,—whether baptism should be administered to infants or adults, or be performed by dipping or sprinkling, &c. Such are some of the points of dispute which have torn the Christian church into a number of shreds, and produced among the different sectaries mutual jealousies, recriminations, and contentions. When we consider the number and the importance of the leading facts and doctrines in which they all agree, it appears somewhat strange, and even absurd, that they should stand aloof from each other, and even assume a hostile attitude, on account of such comparatively trivial differences of opinion, especially when they all profess to be promoting the same grand object, travelling to the same heavenly country, and expect, ere long, to sit down in harmony in the mansions above. The grand principles of hu-

man action, which it is the chief object of Revelation to establish, and the precepts of morality, which ought to govern the affections and conduct of every Christian, are recognised by all; and why then should they separate from each other, and remain at variance on account of matters of "doubtful disputation?"

The evils which flow from such a divided state of Christian society are numerous, and much to be deplored. A sectarian spirit has burst asunder the bonds of Christian love, and prevented that harmonious intercourse among Christians which is one of the chief enjoyments of social religion. It has infused jealousies, fanned the flame of animosity and discord, set friends, brethren, and families at variance, and shattered even civil communities into factions and parties. It has kindled contentions and heart burnings, produced envyings, animosities and hatred of brethren, burst asunder the strongest ties of natural affection, and has led professed Christians to violate the plainest dictates of humanity and of natural justice. It has excited a feverish zeal for the peculiarities of a sectary, while the distinguishing features of Christianity have either been overlooked or trampled under foot. It has wasted money unnecessarily in erecting separate places of worship, which might have been devoted to the promotion of the interests of our common Christianity. It has even corrupted our very prayers, infused into them human passions, and a spirit of party, and confined them to the narrow limits of our own sectary, as if the Omnipotent, whom we profess to adore, were biased by the same prejudices as ourselves, and dispensed his favors according to our contracted views. Could we fly with the swiftness of an angelic messenger through the various assemblies convened on the Christian Sabbath, while they are offering up their prayers to heaven, what a repulsive and discordant scene would present itself, when we beheld the leaders of certain sectaries confining their petitions to their own votaries, imploring a special blessing upon themselves, as if they were the chief favorites of heaven, lamenting the errors of others, throwing out innuendos against rival sectaries, taking credit to themselves as the chief depositories of gospel truth, and thanking God for their superior attainments in Christian perfection! How unlike the noble, benevolent and expansive spirit which Christianity inculcates!—Nay, the intolerance which the divisions of the Christian church have engendered has established inquisitions for the purpose of torturing and burning supposed heretics,—has banished, imprisoned, plundered, hanged, and committed to the flames, thousands and ten thousands, on account of their religious opinions; and many eminent characters, illustrious for piety and virtue, have fallen victims to such unchristian barbarities.

In particular, the divisions and contentions of Christians have been one of the chief causes of the progress of infidelity. The truth and excellence of our religion can only be exhibited to the world by its effects. And when, instead of love, union, and harmony among its professors, we behold bitter envyings, schisms, contentions, and animosities, there appears nothing to allure vicious and unthinking minds to examine its evidences, and to give it an impartial hearing.—"First agree among yourselves," infidels reply, "and then we will consider the truth and importance of your opinions." Such a mode of reasoning and conduct is indeed both absurd and unfair, when the genuine doctrines and requisitions of Christianity are clearly stated in its original records, and which they ought to examine for themselves; but it is a circumstance much to be deplored, that Christians, by their sectarian animosities, should throw a stumbling-block in the way of rational investigation into the truths and foundations of religion, and cause thousands to stumble and fall to their destruction. But what is perhaps worst of all, it has greatly retarded, and still retards, the universal propagation of Christianity through the world. Something has been effected, of late years, by various sections of the Christian church, in their separate capacities; but it is not too much to affirm, that, had they acted in combination and in harmony, in the missionary cause, ten times more good would have been effected than has ever yet been accomplished. Besides, in our present mode of propagating the gospel among the heathen, we are, to a certain extent sowing the seeds of those unhappy dissensions which have so long prevailed

among ourselves. And, therefore, till the different religious denominations in this and other Christian lands be brought to a more general and harmonious union, we cannot expect to behold a rapid and extensive propagation of primitive Christianity throughout the pagan world.

Such are some of the evils which a sectarian spirit has produced in the Christian Church.

A PRACTICAL VIEW OF THE PREVAILING RELIGIOUS SYSTEM OF PROFESSED CHRISTIANS, &c. &c. &c. CONTRASTED WITH REAL CHRISTIANITY. By WM. WILBERFORCE; with an introductory essay, by Rev. DANIEL WILSON, Bishop of Calcutta: 1 vol. KEY AND BIDDLE.

The sensation produced by the publication of this religious work by a layman—by one, too, then occupied and connected personally with the most important measures of the national Legislation,—and which was, as the introduction states, "poured out, as it were, in the interval of two sessions of Parliament," was not ephemeral or transitory. The "Practical View" has held and holds its place as one of the most remarkable and influential books ever published—which wins not more by the earnestness and sincerity of its tone, than by the conciliatory style in which it is written. It is any thing but polemical in its temper and expositions.

It was first published in 1797—when a torrent of infidelity seemed to threaten Great Britain—and when, unless the higher and middling classes could be aroused to the duties and responsibilities of "real Christianity"—all the institutions of religion were in danger of being overthrown. It contributed then mainly to arousing the right spirit, and will serve long to keep it up.

A TREATISE ON WATER-WORKS, FOR CONVEYING AND DISTRIBUTING SUPPLIES OF WATER; WITH TABLES AND EXAMPLES. Charles P. STORROW.—Boston.

This is the title of a small work which has recently been issued from the Boston press. The object of the author, in the language of his preface, was "not to produce an original treatise, but to present the theories of the most eminent philosophers and engineers, on the subject of Hydraulics, in such a form as to be easily understood, and to show, in a simple manner, how they should be applied in solving questions which are, or soon will be, of daily occurrence to the engineers of this country." The habits of persevering industry and patient investigation which distinguish the author, and his reputation as a practical engineer, give assurance that he has treated his subject with ability, and accomplished all a which he aimed. We commend his treatise to public attention as a practically useful and reasonable contribution to the cause of science.—[Communicated.]

WORKS OF ROBERT SANDS.—It gives us pleasure to learn and to state, that a second edition of the works of Sand is about to be published by the Messrs. Harpers.

Messrs. Carey, Lea & Blanchard have received from the author, and put to press, the second part of Geoffrey Crayon's Miscellany. As it treats of Abbotsford and Newstead Abbey, we may expect the most authentic and interesting details concerning Scott and Byron.—[Nat. Gaz.]

#### FOREIGN INTELLIGENCE.

LATER FROM EUROPE.—By the British ship *Arkwright*, from Aberdeen, and the American ship *Joséphine*, from Belfast, dates of 30th March from Aberdeen and Belfast, and 28th from London, are received.

Lord Canterbury, who was about to proceed to Canada, as Commissioner, to inquire into their

grievances, &c. will not now, it is said, owing to some domestic circumstances, come out.

Lord Amherst is appointed Commissioner to Canada in the place of Lord Canterbury.

M. Dumon, as Chairman of the Committee, read the report, which was a detailed analysis of the ground on which the 25,000,000 had been stipulated. It concluded with a bill for the appropriation.

STILL LATER FROM EUROPE.—By the *Poland*, packet ship from Havre, papers of the 10th ult., are received—and the intelligence they bring is every way interesting.

First of our own affairs. The discussion on the American indemnity had commenced. The speech of the Duke of Fitzjames is baldedash from beginning to end, and shows most palpably the weakness of the opposition to the law. The answer of the Minister of the Interior puts the question on the strong ground of justice—and explicitly states moreover, that the measure recommended, is a *Cabinet measure*. As such, strengthened as it was by the avowed support of many members, acting habitually against the cabinet, it could not fail of being carried. It is to be remarked moreover, that the minister refers in his speech to the refusal of the Senate, to grant the President unconditionally, the three millions proposed by the House; so that the closing proceedings of Congress, were known to the Chamber, before the discussion took place—and as there was nothing to follow after, which could affect the solution of the question, it may be considered certain, that the bill has passed.

Of English affairs we speak, we confess, not without solicitude for the future. The defeat and resignation of Sir Robert Peel's ministry, seem to us but the prelude of troubles to come in that country, of which the issue can hardly be for good. Who the successors of the late ministry were to be, was not ascertained at the latest dates—though Lord Melbourne is again talked of as Premier. But he is not equal to the crisis, and could not conduct the country through a single session of Parliament. Perhaps Lord Durham might; but it would only be by yielding to *radicalism* more, than even that anomalous creature, a Democratic Peer, could probably bring his mind to.

Meantime, agitation and uncertainty will prevail in England, and much of the property of the cautious, will probably seek safe investment in this country—a country, happily, which mis-government, however it may disgrace it, cannot ruin.

The death of the youthful husband, of the more youthful Queen of Portugal, is an event that strikes one with the sort of solemn personal interest and regret, always excited by the sudden and mysterious termination of a life eminently brilliant, and full of hope and promise. He died, it would seem, like General Washington, of the croup or quincy, occasioned by taking cold—though, of course, owing to the suddenness of the death, the rumor went forth that he was poisoned.

Of the reported conflict between a Russian squadron and an English ship-of-war, off the Dardanelles, there is no confirmation, and of course, therefore, as the dates by the *Poland* are so much later, it is to be put down, as unfounded.

Havre, 10th April.—The American frigate *Constitution* of 60 guns, Commodore Elliot, arrived yesterday from New-York in our roads. This morning Com. Elliot landed for the purpose of travelling post to Paris, and receiving there the orders of Mr. Livingston.

The *Constitution* has been expected for some days. This frigate is employed as is well known for the purpose of carrying the American Ambassador back to New-York in the now very probable event that the vote of 25 millions will be rejected by the Chambers.

A singular coincidence of facts occurred yes-

terday, connected with the question of the American Indemnity.

Yesterday, the American packet ship *Albany* arrived, bringing back our Ambassador.

In the afternoon of the same day, we learned the arrival in our roads of the American Frigate *Constitution*, for the purpose of taking home Mr. Livingston, the Ambassador of the United States.

And yesterday, whilst these two diplomatic arrivals, so to say, took place, the Chamber was discussing the question of the American indemnity. The very question which led to this arrival of vessels, and recall of ambassadors.

Superstitious persons will perhaps draw from this singular coincidence of circumstances, a favorable or unfavorable augury as to the difficulties between us and the United States. But for our part, we only see in it another reason that the Chambers should act expeditiously in an affair so embarrassing to commercial business and our political relations.

The French corvette *Ceres* arrived at Brest from New York, on the 15th March.

PARIS, April 10.—*Resignation of the English Cabinet*.—Sir R. Peel was on Tuesday again left in the minority on the Resolution moved by Lord John Russell for embodying in the Tithe Bill the appropriation principally recognised in the late motion on the Irish Church, the numbers being in favor of the resolution 285, against it 258—majority against Ministers, 27. The Right Hon. Gentleman had declared in the course of a most able speech, in opposition to the motion, that he could not consent to retain office if it carried, and consequently on Wednesday afternoon he placed his resignation of the Ministry in the hands of the King. This was not positively known (as will be seen by our extracts) when the evening papers went to press, but second Editions have reached us, confirming the important fact of the retirement of the Ministers, which we yesterday (exclusively) laid before our readers.

The Duke of Wellington, on the meeting of the House of Lords in the evening, announced that his Grace, with the rest of his colleagues, had tendered their resignations, and only held their offices until the appointment of their successors. In the House of Commons Sir R. Peel took his seat at 10 minutes before five o'clock, and was received with cheers from both sides of the House. He was followed by upwards of 100 members, who were most anxious for seats, but they were obliged to content themselves with standing at the back and places in the gallery, the House being then full. The Speaker went through his daily list of members in turn to present petitions. Amidst the continued anxiety of the House, not a word could be heard until the Right Hon. Minister rose. He expressed his deep reluctance to take the step which he had felt himself compelled to adopt in laying the resignation of the Cabinet at the feet of his majesty, in consequence of the cordial support he had received from the King, and the confidence reposed in his political views by a great party in the House.

But looking to the little progress made in public business since the commencement of the session, and especially to the votes upon the Irish Church, concluding with that of the preceding night, he had felt, and his colleagues unanimously joined him in opinion, that they could not continue to carry on the Government with advantage to the country. The Right Hon. Baronet, in conclusion, recommended an adjournment until Monday, to give time for making new arrangements, which was adopted, with the understanding, that a meeting for an election case should take place on the following day. Sir Robert left the House immediately afterwards, and was received by the assembled crowd with loud cheers. The Right Hon. Gentleman appeared in excellent spirits, and was followed by a vast number of persons to the Home Office, in Downing street, by whom he was repeatedly cheered.—[Galignani.]

LONDON, MARCH 30, 1835.—Lord Elliot left town on Saturday afternoon for the continent, having been charged by his Majesty's government with a special mission to Don Carlos, with a view of preventing for the future those executions of prisoners, which have hitherto too frequently attended the warfare on both sides.

*Death of Prince Augustus of Portugal*.—The English papers of 6th April, which we just receive, contain the following important intelligence:

Prince Augustus Charles Eugene Napoleon de

Leuchtenberg, consort of the Queen of Portugal, died suddenly on the 28th March.

BET ROOT SUGAR.—A Committee of the French Chambers have made recently a long and elaborate report, on the state of their tariff, and the effect of high duties, in the course of which, the article of imported sugars necessarily led to an examination of the quantity of that staple manufactured in France.

The report "enters at great length into the state of the manufacture of beet-root sugar, and brings to light a variety of circumstances respecting that description of sugar hitherto but little known even in France. It appears that this sugar, not being liable to duties in any way proportioned with those levied on the colonial article, has established a competition in the home market which is highly injurious to the importer of and the dealer in the latter. The number of manufactories of beet-root sugar in various parts of France has been increasing rapidly of late years. Land destined for the cultivation of beet-root is let at a higher rent than for any other production. About 18,000,000 kilogrammes, equal to 36,000,000 lbs. or 18,000 tons a year of the article are manufactured, according to the latest estimates, and the profits it yields to the manufacturer are enormous. The committee recommend that beet-root sugar should be taxed in such a way as to be of advantage to the revenue, without being injurious to the interests of the colonial planter and the refiner of colonial sugar."

Lord Brougham on the presentation of a petition for the abolition of stamp duties on newspapers in England observed, "that the number of copies of papers paying stamp duty, and printed in England, amounted in the whole year (including town and country papers) to 30,000,000; being in proportion to the population 1-25th part of the quantity published in America. The people there, wishing to see the proceedings of the Government, and possessing habits and feelings similar to those of the people of this country, purchased from 1-25th to 1-30th more newspapers (taking the population into account) then were called for here, because in America there was no tax upon newspapers."

SALE OF AMERICAN LANDS IN LONDON.—The London Courier of the 26th March, has this announcement.

An important sale of freehold American lands in the state of Virginia took place on Wednesday, in the Auction Mart, which was crowded to excess with a highly respectable company. Mr. George Robins, in an able and elaborate statement, detailed the property, which was illustrated by maps and drawings. It comprehends a portion of 50,000 acres of carefully selected lands, purchased some years since, under advantageous circumstances, out of 1,800,000 acres. The land is almost exempt from taxes, and the State of Virginia unencumbered by any public debt. The Legislature of Virginia has recently passed an Act for a railroad passing through the lands in question. The selected lands were divided into portions of various sizes from 50 to 100 and 200 acres, each of which possesses the best timber suitable for the building of houses, fences, &c. The yearly average produce of an acre of land giving from 60 to 75 bushels of Indian corn, is net in cash from 1*l*. 2*s*. to 1*l*. 5*s*.; and, varying in quality from 40 to 50 bushels, from 16*s*. to 17*s*. 6*d*. The tobacco crops are very productive. The country abounds in iron, lead, and coal mines, and Mr. Robins urged the important benefits to be derived from purchasing largely in this "the Land of Promise." The tithe and poor rates, were unknown in Virginia; wages were comparatively nothing. Upon a farm of 600 acres, the taxes did not exceed six shillings. The fee simple of one hundred acres of the best quality of land, which in this country would consume 5000*l*. or 6000*l*. might at this sale be obtained for less than 300*l*. The lands were submitted in 91 lots—the first division, 7,265 acres in the country of Logan; the second, 2,517 acres on the waters of the Spruce Fork of Little Cole River. The first parcel, containing 600 acres of land, the yearly average of taxes upon which is about 5*s*. a year, was knocked down for 1,450 guineas. The above lot may serve as a criterion for the whole of the 47 that were submitted. The lots unsmoked Mr. Robins said were open to private contract, amounting to about five thousand acres in various farms, from 50

acres to 500 each, and will be sold by auction in London, on 15th April, in case any of them remain unsold.

SUMMARY.

**BALLOONING.**—The Cincinnati papers contain the following announcement by Mr. Clayton, whose voyage to the mountains of Virginia, excited much interest for a moment. Its success will, we apprehend, have the effect of spoiling a good mechanic, by making him permanently an adventurer, in a career that leads to nothing:

*Grand Aerial Voyage from the Ohio to the Atlantic.*—The Aerial Ship, or Star of the West, which lately made a voyage from Cincinnati to the Alleghany Mountains, 350 miles, in 9 1-2 hours, will take her departure from Cincinnati, about the middle of May, and, if the wind permit, proceed to the Atlantic Ocean.

R. Clayton respectfully informs his friends and the public, that he has made several alterations in his Aerial Machine, which will enable him to continue in the atmosphere a greater length of time than he continued on his last voyage, and that he is desirous of making a voyage, if the wind be favorable, from this city to the Atlantic Ocean.

R. C. will be supplied with a Mail Bag, containing the Newspapers of the day, and a number of letters for the East.

He will take his departure from an Amphitheatre on Court street, between Race and Elm street, at 6 o'clock in the evening.

Due notice of the day of ascension will be given.

The Baltimore American of yesterday, gives this account of another balloon flight.

*The Balloon Flight.*—Mr. Mills and the young lady who accompanied him in his balloon excursion on Monday afternoon, returned to this city yesterday, at noon. According to Mr. M's note of the time, he started from Fairmount at 38 minutes after 4 o'clock. The balloon was wafted by the breeze in a northeasterly direction, and its flight was no near the earth, that the aeronauts exchanged salutations with perhaps a hundred persons on the different farms over which they passed. An occasional change in the currents of air, produced corresponding variations from a direct course, and the voyage was prolonged until a quarter after six, when the weather assumed a squally appearance. Mr. M. then determined to alight, but did not succeed in obtaining a secure grapple for his anchor until, having carried away the pannels of several fences, it was firmly fixed in the branches of an apple tree. The aeronauts then landed in safety, and the balloon was afterwards secured without damage. The spot where they descended was in Peach Bottom township, York County Penn., near the banks of the Susquehanna river.

**MAN-OF-WAR LAUNCH.**—The last Army and Navy Chronicle says—"We understand that considerable progress had been latterly made in preparing the frigate Columbia for launching; this vessel has been several years on the stocks at the Navy Yard in Washington, but no work has been done upon her for a long time until recently.

The Globe states, that owing to the repeated failures of the Eastern Mail to reach Washington, by reason of accidents happening to the engine on the Camden and Amboy Railroad, the Post Office Department "is taking active measures to prevent a recurrence of the evil."

*From Hudson's Merchants' News-Room Correspondent.*

By the Brig Bourne, 50 days from Monrovia, (Africa,) we learn that a brig and schooner, slave traders, with about 1800 slaves, were captured off Cuba by two British men-of-war, and also, about Feb. 1st, at Little Bassa, the slaves on board of a Spanish schooner, about 60 in number, rose upon the captain, whom they shot, and released themselves from their bondage.

[From the Boston Daily Advertiser.]

**THE LATE VOLCANIC ERUPTIONS IN GUATEMALA.** We are indebted to a friend for a pamphlet published in Comayagua, in Honduras, by authority of the Serepine Government of the State, containing a collection of reports from various pub-

lic officers of the remarkable volcanic phenomena which appeared in that region on the 21st, 22d and 23d days of January last. The different reports describe the effects and appearance of the eruption at different places. They are of too great length to admit of giving the whole. The following is a translation of one of these documents:

Official communication from the City of Nacome to the Minister General, of the event from the 20th to the 26th of the present January, being a true copy of the original.

Citizen Minister General of the Supreme Government of the State:—The 20th of the present month, at half-past 6 o'clock in the morning, a port took place as of the discharge of many heavy cannon, twelve minutes after the commencement. It continued until a quarter past 12, when a violent shock took place, which was then the prelude of a new eruption; the rumblings now continued was observed upon the summit called Cosiguina, which arose in a pyramidal form, with so many hues, and of such density, that we immediately presumed it to proceed from a volcanic eruption. At some height it separated into two parts, one spreading over the summit of Coneagua, and the other towards the Peak of Pespire. Up to this time, nothing more was heard than dull subterraneous noises, nor had any trembling been felt. The cloud continued to spread, and the general alarm increased. At half-past ten, there no longer remained a doubt of the malignity of this phenomenon, then extending itself with greater rapidity over this place. At half-past 11, it became necessary to use artificial light, and at 12, we were involved in a general darkness which it is difficult to conceive, nor does any traditions exist of such, in events of this description. Public prayers were immediately determined to be offered up by the inhabitants and their worthy pastor. At half-past 2 in the afternoon, by the light of torches and candles, a supplicating procession moved. A little before, a shower of fine sand had commenced falling. In its course, the wind from the east having greatly increased, precipitated such a quantity of a kind of ashes or calcined dust, (powder,) that many persons found it difficult to follow in the procession, or even to find their own houses, and some shocks now began to be felt. At 5 o'clock in the afternoon, the ground was covered to the depth of three inches with this dust; at 6 o'clock its density was diminishing considerably, leaving the respiration more free. In the midst of great affliction, and in the performance of acts of religion, we passed that memorable night of mourning and alarm. At 11 o'clock on that night, and at four in the morning, there were two violent shocks, and alternately various slight ones, all preceded by rumbling, as well as sharp detonations, which were heard from an early hour in the evening. The 21st, the day dawned serenely, dissipating in some measure our apprehensions. At 8 o'clock in the morning, our hopes were dampened, on finding that the great quantity of volcanic matter with which the atmosphere was charged prevented the passage of the rays of the sun, which, however, for some moments displayed an opaque and sulphurous surface. On this day, the dust fell in less quantity, and much finer. In the same manner the shocks continued strong and slight. During the night of the same, the noises and reports which have been already mentioned, continued. At the dawn of day, the shower of dust was abundant. We had arrived break of day on the 22d, without our sad situation having been ameliorated; on the contrary, the opacity was greater. The noises and shocks continued. The neighborhood of this city, its square (or citadel) and streets, were covered with four or five inches of the exhalations mentioned, and so fine that at the least breath of air they would rise, filling the organs of respiration; the trees in the fields, the roofs of houses were the same, and the rivers were infected by a baneful stench.

In this situation, this municipality, with the concurrence of their pastor, thought proper to assemble the inhabitants for the purpose of adopting suitable measures for the exigency. The only ones which have occurred until now, is to endeavor to wet the dust, which we believe to be most injurious to health, and to supply the people

with provisions. In both which the inhabitant<sup>s</sup> have assisted with promptness, as well by their personal services, as pecuniary, considering in the meantime what other measures of policy and salubrity they might adopt. On this day, the horizon was observed to become clear, and the atmosphere freer. From time to time slight shocks and rumblings were experienced. The evening twilight was clear; the stars were soon discovered; the sky became considerably clear, and at 12 o'clock at night praises and thanksgiving to the Supreme Being were heard, for the now ascertained improvement of our critical situation. But at this very hour, a rumbling noise was heard, which continued increasing without interruption until a violent retinue with some intervals of a frightful silence. A dark column was seen to ascend anew from Cosiguina, covering this place, concealing the stars and filling our hearts with mourning and affliction, now terrified by the incessant noise for a quarter of an hour of the dreadful reports and shocks. At 5 o'clock on the morning of the 23d, day broke without witnessing any increase in the clearing of the atmosphere, which however was sufficient to discover the cloud and new eruption which threatened us. Prayers and supplications to the Omnipotent God began; each quarter of an hour augmented the general terror; this reached its greatest height at half past 8, when the darkness considerably decreased the little clearness of the twilight. This whole population believing that their last hour had now arrived, was assembling every moment in groups of persons of all sexes and all classes at the house of our venerable pastor, and with lamentations and sobs begged for absolution from their sins. The latter, who unfortunately was quite ill, absolved them in part, until notwithstanding his painful situation, he repaired to the square, that he might be the better able to excite them to contrition, to absolve them as he could in such terrible circumstances. At 9 o'clock all terminated, and a scene more terrible than any preceding began. The dreadful rumblings were repeated, the sky, notwithstanding the darkness, displayed reddened glares, which excited fears of the atmosphere being enkindled. At half past 10, thunders were heard in various directions, with sharp lightnings, caused by the combustible matter floating about in our atmosphere; the same effects, without any difference, which the most violent tempest causes in the most rainy months of winter. In short, Sonor Minister, every description falls short of giving an idea of this memorable event, no expressions can be found to convey it. The darkness continued the whole of the day, the noise and rumblings began to subside at two o'clock in the afternoon, the dust with which the cloud was impregnated fell abundantly, accompanied by fine sand: night arrived, which was passed in the deepest consternation, awaiting the day-break to disperse the darkness which had continued uninterrupted, except for a very short time, for the space of 36 hours. On the 24th at day-break, although somewhat clear, the atmosphere was loaded with vapors like whirlwinds of dust, which the slightest wind raised, and it was considerably obscured. The 25th and 26th continued in the same manner. Our grounds and buildings are covered to the depth of seven or eight inches with the pulverized matter mentioned, in which are found birds of all kinds suffocated. Some quadrupeds from the forest have sought for shelter in this town, and the rivers filled with the same substance have cast upon their shores an innumerable quantity of fishes in a torpid state, and some dead.

This body in drawing up the preceding relation does not pretend to give an exact picture of an event so frightful, but with the greatest care and circumspection it can scarcely be sketched, all minds being too much overwhelmed in consternation to describe it in any other way. We intend nothing more than to lay before the Supreme Government the notice of so fatal a catastrophe, sufficient to enable it to give promptly adequate orders for the remedy of our disaster.

Be pleased, Citizen Minister, to communicate this to the Supreme Government, and accept the assurances of esteem and respect to which this corporation has the honor of subscribing.

NACOME, January 26, 1835.—Placido Jacquin, J. M. Boquin, Antonio Alcano, Jacinto Boijas, Antonio Gutierrez, J. Domingo Castillo, Juan Mojia, Francisco Dias, Secretary.

**PHYSICAL EDUCATION.**—From a discourse on "the Dangerous tendency to Innovations and Excesses in Education," by the Rev. H. Wadsworth, the following remarks on what is called "physical education," are entitled to attentive consideration:

Temperate and judicious exhibitions of the nature and importance of physical culture, are timely and important; but the ultra notions are becoming prevalent, that large physical development and high toned physical energy constitute the substratum of mind, and are essential to the loftiest intellectual achievements. Hence the abundance of declamation and loose remark upon the importance of gymnastic exercise. At some of our schools and colleges, gymnasia are constructed for the express purpose, it would seem, of educating the muscles. Other literary institutions embrace a system of manual labor, laying under demand a considerable portion of their pupils' time. As though great strength, agility and magnitude of the physical system were essential to the student's object, the doctrine is becoming popular, and he who would aspire to long life and intellectual eminence, must make a large sacrifice of time and attention to the same kind of discipline with those whose employment for life is to be physical labor.

As far forth as systems of manual labor in connection with literary institutions can subserve needed pecuniary ends, they have their importance; but their ultimate and prolonged success is questionable. That so much of the exercise and strength of the laborer should be put upon the student, as the modern doctrine teaches, seems to be against both nature and experience. Even *a priori* reasoning would teach us, that if God has intended a division of labor, he has so constituted the human system that it may be trained to different pursuits. All mankind are destined to some degree of mental cultivation; but he who is to be professionally engaged for life in intellectual pursuits, must be as far as possible *free in idea*, and must therefore train himself to the least physical necessities and to the greatest and most continued intellectual effort practicable, leaving the more special cultivation of stature and muscles to those who have a more special use for them.

The calling of the laborer is as honorable, useful and important as is that of the student, but these two callings do not require the same kind of training, either physically or intellectually; nor is the physical system of the student to be kept in the same condition with that of the laborer, any more than the intellectual system of the laborer is to be kept in the same state with that of the student. Man was not designed to be a *factotum*. Let so much of his time, thoughts, and feelings be expended upon his physical cultivation as is requisite to develop all his physical powers in their utmost strength and luxuriance, and so much goes to the animal that ordinarily little goes to the intellectual. That physical perfection is not essential to mental eminence, is evident from the fact that men of the most distinguished minds have even usually had a thorn in the flesh.

Exercise and recreation are important to the student, but they should be such as to improve and interest his mind, while they benefit his body. Botanical, mineralogical and geological excursions; exploring the curiosities of nature; occasionally unbanding with music and the fine arts; a morning walk with Thompson, and a little of the elixir of

comfortable the student's accommodations, how spacious and airy his room, how commodious his desk, whether he sit upon a naked bench or a cushion; we would only have him avoid notions and extremes, think as little of his body as possible, and adopt the simple style of living appropriate to his calling. As to that all important organ, the stomach, the seat of life and sensibility, the source of so much joy and sorrow to man while man is mortal, we consider it a blessed ignorance if no symptoms shall ever admonish him that he has one.

But public attention is now directed from the stomach to the head. The craniological fever is on, and will have its run. Blessed is the man now, who has a fine skull! Any novice, who has just taken a peep into anatomy and physiology and their vital connexion with mental science, who has read Bober, Broissens and Combe, but especially Gall and Spurzheim—can determine the intrinsic phenomena of his neighbor's mind, with the place and manner of its growth; and, by accurate and sensible demonstration, can reveal its character and size, with an accuracy which will surprise a future generation. The venerable doctrine of heathen India, that the intellectual and moral fate of every man is written in the sutures of his skull, is springing up among us with the pretended charms of novelty, though somewhat disturbed of its oriental beauty. Phrenology, thoroughly studied and understood, unfolds some interesting general facts, but the present charms of its details are adapted to fascinate unanalyzed minds of fanciful temperament, rather than minds of a severely intellectual and scientific character.

Allowing brain to be the organ of intellectual operations and members of sensibilities and moral affections, which we believe to be sound doctrine, or admitting the more popular doctrine, that all the operations of the soul have pitched their tent together in the head, is not the quality and condition of brain as important as the quantity and shape? The vigor of the hepatic secretions does not depend so much upon the shape and size of the liver, or of the ductus choledochus, as upon its quality, its healthfulness, its right condition in point of adaptation to other related organs. So of all the physical organs and functions, in their relations both to the body and to the mind. So many facts and circumstances, not obvious to external inspection, are connected with their vigorous or feeble operations, that we are slow to forestall our judgement of men by the appearance of their heads, or any other external marks. With becoming deference therefore to the splendidly important and interesting sciences of craniology, ophthalmoscopy, nosology, physiognomy, gastronomy, dermology and myology, all of which have found their advocates and are entitled to their day, which afford amusement, and help the confident to know and the wise to guess, we must still be allowed, when we would sit in sober judgement upon men, to adhere to the good old fashion, and judge every man mainly according to his deeds; and not by the volume or protuberances of his cranium and the height and majesty of his forehead; or by the shape, magnitude and polish of his eye; or by the contour, elongation and luxuriance of his nose; or by the configuration and cast of his face; or by the periphery, diameter and longitude of his perimetrium; or by the complexion and texture of his epidermis; or by the strength and rigidity, or the feebleness and beauty of his muscles.

#### The Supreme Power.

[From an eloquent article in the *North American Review*, by Edward Everett.]

"It has been as beautifully as truly said, that the devout astronomer is mad." The same remark might with equal force and justice be applied to the devout geologist.—Of all the absurdities ever started, none more extravagant can be named, than that the grand and far-reaching researches and discoveries of geology are hostile to the spirit of religion. They seem to us, on the very contrary, to lead the inquirer, step by step into the more immediate presence of that tremendous Power, which could alone produce and can alone account for the primitive convulsions of the globe, of which the proofs are given in eternal characters, on the side of its bare and cloud-piercing mountains, or are wrought into the very substance of the strata that compose its surface, and which are also day by day, and hour by hour, at work, to feed the fires of the volcano, to pour forth its molten tides, or to com-

pound the sublimous elements of the mineral fountain, which spring in a thousand valleys, in gazing at the starry heavens, all glorious as they are, we sink under the awe of their magnitude, the mystery of their secret and reciprocal influences, the bewildering conceptions of their distance.—Sense and science are at war.—The sparkling gem, that glitters on the brow of night, is converted by science into a mighty orb,—the source of light and heat, the centre of attraction, the sun of a system like our own. The beautiful planet, which lingers in the western sky, when the sun has gone down, or heralds the approach of morning,—whose mild and lovely beams seem to shed a spirit of tranquillity, not unminged with sadness nor far removed from devotion, into the very heart of him who wanders forth in solitude to behold it—is in the contemplation of science, a cloud wrapped sphere; a world of rugged mountains and stormy deeps. We study, we reason, we calculate. We climb the giddy scaffold of induction up to the very stars. We borrow the wings of the boldest analysis and flee to the uppermost parts of creation, and then shutting our eyes on the radiant points that twinkle in the vault of night, the well instructed mind sees opening before it, in mental vision, the stupendous mechanism of the heavens. Its planets swell into worlds. Its crowded stars recede, expand, become central suns, and we hear the rush of the mighty orbs that circle round them. The bands of Orion are loosed, and the sparkling rays, which cross each other on his belt, are resolved into floods of light, streaming from system to system, across the illimitable pathway of the outer heavens. The conclusions which we reach, are oppressively grand and sublime; the imagination sinks under them; the truth is too vast, too remote from the present, from which it is deduced; and man, poor frail man, sinks back to the earth, and sighs to worship again, with the innocence of a child or Childan shepherd, the quiet and beautiful stars, as he sees them in the simplicity of sense.

But in the province of geology, there are some subjects, in which the senses seem, as it were, led up into the laboratory of divine power. Let a man fix his eyes upon one of the marble columns in the Capitol at Washington. He sees there a condition of the earth's surface, when the pebbles of every size, and form, and material, which compose this singular species of stone, were held suspended in the medium, in which they are now imbedded, then a liquid sea of marble, which has hardened into the solid, lustrous, and variegated mass before his eye, in the very substance of which he beholds the record of a convulsion of the globe. Let him go and stand upon the sides of the crater of Vesuvius, in the ordinary state of its eruptions, and contemplate the lazy stream of molten rocks, that cooes quietly at his feet, encasing the surface of the mountain as it cools with a moss black and ashy crust, or lighting up its sides at night with streaks of lurid fire. Let him consider the volcanic island, which arose a few years since in the neighborhood of Malta, spouting flames from the depth of the sea;—or accompany one of our own navigators from Nantucket to the Antarctic ocean, who finding the centre of a small island, to which he was in the habit of resorting, sunk in the interval of two of his voyages, sailed through an opening in its sides where the ocean had found its way, and moored his ship in the smouldering crater of a recent extinguished volcano. Or, finally, let him survey the striking phenomenon which our author has described, and which has led us to this train of remark, a mineral fountain of celebrated qualities, of a temperature greatly above that of the surface of the earth in the region where it is found, compounded of numerous ingredients in a constant proportion, and known to have been flowing from its secret springs, so at the present day, at least for eight hundred years, unchanged, unexhausted. The religious scenes of the elder world, in an early stage of civilization, placed a genius or a deity by the side of every spring that gushed from the rocks, or flowed from the bosom of the earth. Serley it would be no weakness for a thoughtful man, who should resort, for the renovation of a wasted frame, to one of those sublimous mineral fountains, if he drank in their healing waters as a gift from the outstretched, though invisible hand, of an every-where present and benignant Power.

From "The Memoirs of celebrated Women," recently republished among us, we take a notice to-day of one, whose youth, loveliness, extraordinary acquirements, and early fate, appeal with great force to the heart and the imagination.

Lady Jane Gray.

[From *Memoirs of Celebrated Women of All Countries*. By Madame Junot.]

Ambition punished, seldom excites pity; but can a tribute of commiseration be refused to a beautiful woman, only seventeen years of age, who laid her head upon the block to expiate the ambition of another? Such was the fate of Lady Jane Gray! A crown had no attractions for her—she had no desire to reign! It seemed as if this unfortunate and lovely young creature felt her feet slip on the very steps of that throne which the Duke of Northumberland forced her to ascend. A warning presentiment told her that a life of quiet seclusion was the only means she had of escaping a violent death. She long resisted the fatal counsel of her father-in-law; but she was dragged on by her evil destiny.

Lady Jane Gray, born in 1537, was the granddaughter of Mary Tudor, sister of Henry VIII. This princess, being left a widow by the death of her husband, Louis XII. King of France, and having no children by this marriage, returned to England and married Brandon, Duke of Suffolk, whom she had long loved, and who was Lady Jane's grandfather. The subject of this memoir, when she was scarcely sixteen, married Lord Guildford Dudley, fourth son of John Dudley, Duke of Northumberland. Lady Jane Gray was beyond measure lovely: her features were beautifully regular, and her large and mild eyes were the reflection of a pure and energetic soul, though peaceful and unambitious. She had a strong passion for study, especially that of abstruse science. Though young, she had acquired vast learning, and was deeply read in the ancients: she was very familiar with Greek, and extremely partial to Plato. Living at one of her country seats, she divided her time between her books and her husband, until political events of high importance troubled her peaceful life and destroyed her happiness.

Edward Seymour, Duke of Somerset, Protector of England, exercised over that country a despotic sway to which the nobles would no longer submit. The latter, equally disgusted with the pride of Thomas Lord Seymour, the Protector's brother, applauded the Duke of Northumberland when he succeeded in successively removing these two favorites from the king's person; and Northumberland thought himself popular, when he was only loved on account of his hatred to the Seymours. Edward VI., a weak and sickly child, who could ill bear the weight of the crown that encircled his pallid brow, always bestowed his favor upon those near his person, and Northumberland succeeded Somerset. But the new favorite, fearing, and with good reason, that he should not long retain this station, as the King might die, and was indeed then dying, though only sixteen years of age, employed, with considerable address, the prejudices of religion to gain his ends. He described to Edward, in hideous colors, the character of his sister, Mary the Catholic; and represented in an equally unfavorable light, Elizabeth, daughter of that Anna Boleyn who was condemned and executed for adultery. Could then the crown of England, he asked, be placed upon a dishonored brow, or the welfare of the English nation be entrusted to an intolerant fanatic? Northumberland was a man of ability: he shook the timid conscience of Edward, who, fearing Mary's violence, and prejudiced against Elizabeth, changed the order of succession, and designated as his successor, Jane Gray, the eldest daughter of Henry Gray. On the King's death, Lady Jane was, through the exertions of Northumberland, proclaimed Queen. In vain did the lovely young creature entreat her father-in-law to allow her to retain her freedom: the obstinate Duke, always at the head of intrigues, determined to gain his point with her whom he deemed a child. "Shall it be for nothing," said he, "that I have caused the daughters of two queens to be declared illegitimate in order to place the crown upon the head of my daughter-in-law? No indeed!"—The ambitious old man sent for the princesses Mary and Elizabeth to London, without informing them of the King's death, which he kept con-

cealed. But Mary, being acquainted with Northumberland's projects, escaped the snare; and steel made her triumph over the obstacles which he placed between the throne and herself.—Steel!—steel, flames, and scaffolds, were about to constitute the laws of Mary the Catholic—of Mary the bloodthirsty!

She soon entered London, with prayers on her tongue and vengeance in her heart. In vain did Northumberland resist her: he was vanquished, deserted by every one, and together with Lady Jane Gray and his son, Lord Guildford Dudley, imprisoned in the Tower.

Poor Jane Gray!—she had resisted her father-in-law's wishes only to yield to them and die after a reign of nine days!—for the unfortunate and lovely woman reigned no longer. Scarcely had she placed upon her head that crown so fatal to the touch—which falls but to drag the heads of kings along with it—ere she was shut up in a dungeon soon to lay her head upon the block! Alas! she had a presentiment of her fate, when she refused to exchange her diadem of flowers for the regal crown of England.

Meanwhile, Mary considered that the death of Northumberland alone was sufficient to appease her vengeance and secure her peaceful possession of the throne. Lady Jane Gray and her husband were confined in the tower of London;—in the same place as that Elizabeth, who was destined at a later period to show the world that a woman may become a great sovereign. For a time, Mary suffered Lady Jane Gray to live, because she thought that, being queen of England both by right and force, she might reign in future without taking away the lives of her enemies. But such are the dreadful consequences of violence, that, when once adopted, the only road left open is one of bloodshed; and to deviate from it then is impossible.

Mary was a Catholic and a bigot; and being betrothed to Philip of Spain, she was anxious to offer a nuptial present worthy of him who was one day to become the father of Don Carlos. She therefore commanded that all her subjects throughout England should submit to the See of Rome; and as the English then professed the Reformed religion, and were attached to it, Mary directed also that scaffolds should be erected, and piles of fagots raised for burning heretics. On the issuing of these orders, insurrections broke out in every part of the kingdom. The Queen shuddered whenever she heard the names of her sister and her cousin; she stormed with rage at the people who called for Lady Jane Gray; and to silence them—to answer their call—she threw them the head of that unhappy lady!

Poor Jane! Thou wert dragged from thy peaceful retirement to be placed against thy will upon a throne, and to fall from it into a dungeon! The ministers of vengeance and fanaticism are now come to drag thee from thy prison, and force thee upon a scaffold!

Mary was alarmed at the cries of sedition uttered by the people. Lady Jane and her husband were brought before an iniquitous council, who condemned them both to die; and the Mayor of London having begged that a public example might be made, obtained that Lord Guildford Dudley should be executed in public. The unfortunate nobleman, on his sentence being communicated to him, requested an interview with his wife. She refused to see him, but wrote him a letter to the following purport:

"Do not let us meet, Guildford—we must see each other no more until we are united in a better world. We must forget our joys so sweet, Guildford, our loves so tender and so happy.—You must now devote yourself to none but serious thoughts. No more love, no more happiness here upon earth!—we must now think of nothing but death! Remember, my Guildford, that the people are waiting for you, to see how a man can die. Show no weakness as you approach the scaffold; your fortitude would be overcome, perhaps, were you to see me. You could not quit your poor Jane without tears; and tears and weakness must be left to us women. Adieu, my Guildford, adieu! be a man—be firm at the last hour—let me be proud of you."

Guildford died like a hero, and Jane was proud of him. Ah! it was not from weakness that this noble minded creature refused the crown;—she was happy with her books, her affection, and her beloved husband, under her own labours of

flowers. It was the absence of happiness, in a crown, not its weight that alarmed her.

She saw her husband leave the Tower and proceeded to the place of execution. She prayed a long time for him; her own turn then came; and she prepared for death. Mary, desirous of increasing her sufferings, pretended to convert her, and offered to pardon her if she would abjure the reformed religion. But with a sweet smile of sadness, she refused. For at that time what was life to her?—nothing but a vast solitude through which she should have to wander alone and deserted. She preferred death!

For three days she was assailed by the importunities of Catholic priests, who thought they had shaken her faith. Jane made them no reply, but continued her prayers. Having written a last letter of adieu to her sister, the Countess of Pembroke, she took off her mourning, dressed herself in white, had her long and beautiful hair cut off by her female attendants, and walked boldly to the place of execution. When, however, she saw the sparkling of the steel axe, she turned pale. She knelt, prayed again, lifted up her eyes and looked at the heavens!—then placing her head upon the block, she received the stroke that conferred upon her a crown of which no human passions could deprive her—the crown of martyrdom!

This was the third time in London, within a period of twenty years, that the blood of a queen had stained the scaffold. The reign of Elizabeth was to present a fourth act of the same tragedy.

Catherine Gray, Countess of Pembroke, was more to be pitied than her sister Jane; for, after all, what is death to any one who has lost every thing that makes life valuable! But Catherine, separated from a world in which the man she loved still lived, must often have prayed to God to give her the sleep of the grave.

Catherine Gray had married the Earl of Pembroke; but their union was so unhappy that both demanded a separation, and their marriage was dissolved by a judicial act. She then became the wife of the Earl of Hertford, who set out for France, leaving her pregnant. Catherine Gray being of the royal blood of Tudor, her marriage without the consent of her sovereign was imputed to her as a crime; and on ascending the throne, Mary, as happy in having to inflict punishment as another would have been to show clemency, condemned her to imprisonment for life. The Earl of Hertford on his return from France, was also sentenced to imprisonment, and the Archbishop of Canterbury declared the marriage null and void. Nevertheless the Earl protested against the sentence of the Archbishop, as well as against that of his other judges. He loved Catherine with the tenderest affection; and still looking upon her as his wife, bribed the keeper of the tower and obtained access to her prison. Catherine became a mother a second time; and Mary persecuted the Earl of Hertford with all the vindictive hatred of a Queen whose authority is despised, and of a woman already past the age of inspiring love, who cannot forgive young people for their superiority in this respect. The Earl's accusation consisted of three counts: First, of having seduced a princess of the royal blood; secondly, of having violated a state prison; and thirdly, of having approached a woman from whom the law had separated him. He was condemned to a fine of five thousand pounds sterling for each offence. He paid the fifteen thousand pounds, and after a long confinement consented to sign a voluntary act of separation from Catherine; but not till after a long struggle, and a resistance which bore ample testimony of the strength of his attachment.

The unfortunate Catherine Gray died in prison, in 1562, after a long and painful captivity. Like her sister Jane, she was learned and fond of study. Both were young and lovely, and the fate of both showed that royal birth is no security against misfortune. Tears are shed in the palaces of kings as well as the peasant's hovel; and arms loaded with jewels often bear the chains of captivity. Poison is sometimes drunk in a cup of gold, and the crowned head severed by the executioner's axe!

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order cast wheels, chairs and knees, and every other description of castings required for railroads. R-17 Feb 14

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, MAY 16, 1835.

**CANALS AND RAILROADS.**—We commence in this number the Report made to the Canal Commissioners of this State, by John B. Jervis, Holmes Hutchinson, and Frederick C. Mills, Esqrs., Civil Engineers, upon the relative cost of, and cost of transportation on, Railroads and Canals. It contains much useful information, and should be read with care by those interested in such works.

It does not require a very close examination to discover the kind of improvement preferred by the gentlemen who made the Report. They appear to entertain, as many other very intelligent men do, the opinion that Railroads cannot compete successfully with Canals.

Of the correctness of this opinion, as it relates to transportation of heavy articles, we are not disposed at present to object; but for purposes of travel, light freight and the mails, Railroads must, we think, supersede all other modes now in use. We ask for this report an attentive perusal by Engineers, and offer the columns of the Journal for a proper discussion of the subject by those who have the leisure and disposition to enter into it—neither of which, nor the ability, is possessed by us.

The Pittsburg Gazette, advertising to the benefit which, what are called "the cross-cut canals"—the things that will connect the great Pennsylv-

nia Canal at Pittsburg with Lake Erie at Cleveland by the route of the Ohio Canal—will confer on Pennsylvania, and Pittsburg in particular, exclaims—

"Pennsylvania, Philadelphia, and Pittsburg are truly in the full tide of successful experiment—their destinies are rapidly unfolding themselves. When these junction canals are completed, New York will have to execute a release of all claim upon the trade of Ohio."

New-York will not, we trust, much longer pursue the suicidal course in relation to the Trade of the West, which has marked her late legislation. She will never, never "execute a release." She merely rests her claims for a time, to witness the eagerness with which her neighbors labor for the prize.

**WEVERTON MANUFACTURING COMPANY** is the title of a company formed in Maryland, for the purpose of carrying on the manufacturing business in its various branches. The situation selected for its operations is on the Potomac, about three miles below Harper's Ferry, and immediately on "the lines of the Baltimore and Ohio Railroad, Chesapeake and Ohio Canal, and Frederick and Harper's Ferry turnpike road. At Harper's Ferry these three great avenues of communication separate, and embrace in their respective ranges, a very extensive, fertile, and populous country. Immediately below, the turnpike road leaves the river, and crossing a most productive country reaches the city of Frederick in a distance of sixteen miles. Nine miles below, at the Point of Rocks, the canal and railroad separate, the latter passing on to the city of Baltimore, and the former running to the three cities in the District of Columbia. A railroad to diverge from the Baltimore and Ohio Railroad at Weverton, and to run to Hagerstown, Maryland, and Chambersburg, Pennsylvania, is contemplated, and no doubt will be soon constructed."

Thus we see the effects of the system of internal improvements adopted, and with so much zeal carried on, in this country—villages, towns, and cities, springing up in every part of the country, where, but for

such improvements, the click of the hammer would never be heard.

"The power proposed to be employed by the Weverton Manufacturing Company, is the water of the Potomac river. The fall which may be commanded without an artificial dam, is upwards of eight feet, but three or four feet more could be obtained by the construction of a dam on the ledge of rocks which now forms a natural dam."

A company is formed for the purpose of improving the advantages of the place. Col. Mauley, a gentleman of high respectability, is now in this city for the purpose of receiving subscriptions to the stock. He has left with us copies of the charter, and a description of the place, which may be seen by those who desire information upon the subject.

A Friend to Canals and Railroads will find in the Railroad Journal, if he uses it, the most extensive, and probably the most careful investigation of the subject of canal navigation, that has been published. He will find, however, that according to these experiments, broad canals are not considered by Mr. Macneill as best adapted for speed.

To the Editor of the Mechanic's Magazine:

In the valuable letter of Gerald Balston, in your last number, he speaks of General Mercer truly as the "advocate of broad and deep canals for transportation." He also advocates, and has long endeavored to draw the attention of those interested in canals, to the use of the Paisley passage boats. The principle on which their success has depended has not yet been demonstrated. But those on which he has advocated the superiority of wide and deep canals for transportation have been long known, and their truth admitted. An exemplification is given in the difference of strain on the horses on the Schuylkill canal; on the narrow canals it is hard, on the pools, easy.

You could not better serve the cause of internal communication, than by accepting the offer of Mr. Balston, and request him to give all the information which his time and opportunities will permit on the subject of these swift canal boats.

—A FRIEND OF CANALS AND RAILROADS.

Report of John B. Jarvis, Holmes Hutchinson, and Frederick C. Mills, to the honorable the Canal Commissioners of the State of New-York:

GENTLEMEN: We have examined the question you submitted to our consideration, in relation to the relative cost of construction and repairs of canals and railroads, and also the relative expense of transportation, and present in the following report the facts and views we have been able to obtain. The importance of the subject compels us to regret that more time could not consistently have been taken, to obtain further facts, and allowed us to carry the investigation into greater detail. We have felt compelled, in a great degree, to confine ourselves to an exposition of prominent features, in the two methods of facilitating internal communication. We believe, however, the facts presented, and the exposition of the bearing of those facts, will be found useful, in leading to correct conclusions in regard to the question under consideration.

#### RAILROADS.

The utility of railroads is materially, and in some respects, peculiarly affected by the ascent and descent that is overcome, and the relative amount of trade requiring transport in opposite directions. For instance, a railroad requiring transport only in one direction, would be most favorable with such a declivity in the direction of the freight, as would require the same power to move the loaded wagons, as would be necessary to return with the empty ones: and this declivity would decrease in cases requiring transport in both directions, and become level when the freight was equal.

In this country, it rarely occurs that freight is equal in both directions; more frequently it is 2, 3, and 4 to 1. To obtain the most favorable graduation to the trade to be accommodated, it is essential that it be uniform, or nearly so; which the route would not often admit without too great expense, and in some cases would be impracticable. On important lines for general trade that have any considerable extent, there will, from the character of the country, often require a level, and sometimes a small ascent, in the direction of the greatest trade; and it would be a favorable compromise to exchange all acclivities and declivities for a level road. Though there would be exceptions, still it is believed a level road would afford a fair standard in determining the general question of utility.

Below will be found a statement of the cost of several railroads, and in some cases the cost of transportation.

It is to be regretted that more authentic information of a practical character is not in our possession. The authorities, as well as the facts, are stated to show the weight

in some instances; and these for conclusions.

Road.  
f. Rocks, 67 1/2  
ineer, (Octo-  
stated to be  
\$29,193 per  
cond session  
asserted this  
000 per mile.

ers, and find  
at of \$29,193

is done in a  
er; over 3 of

the superstructure is timber sills and rails, capped with an iron plate; 1/2 (or 3/4) is stone rails capped with iron plates; and 1/4 is timber rails on light stone blocks.

The cost of transportation for the year ending 31st September, 1854, as per report of superintendent of transportation, was for motive power and all other charges, (excluding repairs of road,) except interest and fund for renewal of wagons, \$62,348 57

Superintendent of machinery reports 1,000 wagons on the road; their cost is not given. They probably cost from \$150 to \$200 each; if on steel springs, the latter, otherwise the former: they may be estimated at \$150 each, which for 1,000 is \$150,000, interest on their cost, and to provide a fund for renewal, is believed should be at 25 per cent., which is, 37,500 00

Total cost of transportation, exclusive of tolls or profit, for 56,190 tons, is, 99,848 57

The average charge of the company, per said report, is within a small fraction 4 1/2 cents per ton per mile, produces the sum of 116,254 76

The ratio of receipts to expenditures is 1 to 0.85, and  $4.66 \div 0.85 = 5.48$  cents per ton per mile, as the expenses.

The expenses the previous year are stated by same report to have been higher: but as we have not the detailed statement, we cannot give the exact difference.

This railroad has ascents, descents, and curves, which affect the economy of transportation.

In regard to curves, this road may be considered as having more than is usual on railroads, designed mainly for general trade.

All lines of railroad, of any considerable extent, will be curved more or less, according to the character of the country through which they are constructed. It is the first object to have it straight, and next, the lightest curvature the country will admit: the minimum will therefore, be determined by local circumstances. While it is considered this road has more curvature than will occur as a general average, it is obviously impracticable to determine what this average may be. The chief engineer, J. Knight, of this (Baltimore and Ohio) railroad, made experiments on the increased resistance produced by curves, which led him to the conclusion, that in a curve having a radius of 400 feet, the traction was increased 50 per cent. If locomotive engines were used, then loads would be regulated by the greatest resistance they had to overcome, on any part of the route; but a horse can increase his effort, for a short distance, which enables him, on a road that has occasionally sharp curves or ascents for moderate distances, to perform a greater average of useful effect than can be obtained from locomotive steam power. The freight business for this road is performed by horse power. The sharpest curves generally occur in short distances, intervening between straight lines and larger curves, and will not, therefore, affect the cost of transportation to so great a degree as if locomotive steam power was used. If we assume 10 per cent. of the resistance on a level and straight line, as the excess over a general average arising from extra curvature on this road, and apply it to the section between Parr Ridge and Baltimore, we shall not probably be far

from its true influence on the cost of transportation.

The next and most important question that affects the cost of this transportation is the ascent and descent. The character of this road in relation to its elevations, seems to indicate the propriety of dividing it into sections, and applying on each the power necessary, without regard to the other. The following divisions have therefore been made, to wit:

1st. From Baltimore to Parr Ridge, foot of 1st inclined plane—length, 4 1/2 miles; ascent westward, 590 feet; descent, 23 feet; total, 613 feet; ascent averages 14.75 feet per mile.

2d. Embraces the 4 inclined planes that pass Parr Ridge, 1.94 miles; ascent and descent, 439 feet, viz.:

No. 1, 2,150 feet, rise  $\frac{1}{10} = 215$  feet; No. 2, 3,000 feet, rise  $\frac{1}{10} = 300$  feet. Total ascent, 179 feet.

No. 3, 3,800 feet, fall  $\frac{1}{10} = 380$  feet; No. 4, 1,900 feet, fall  $\frac{1}{10} = 190$  feet. Total descent, 241 feet. Whole amount 420 feet.

Intermediate level, about 3 1/2 miles.

3d. From foot of plane No. 4, to end of continuous declivity westward, 1 1/2 miles; total descent, 235 feet; average, say 25 feet per mile.

4th. The remainder of road, to Point of Rocks and branch to Frederick, a fraction over 16 miles; descent westward, 169 feet; average 10.56 feet per mile; ascent westward, 191 feet. Total rise and fall, 500 feet.

The ascent westward, for the 4 divisions, is 908 feet. The descent westward, for do. 718 "

Total ascent and descent, 1,618 "

By the report referred to, it appears the ratio of freight moving eastward to that moving westward, was nearly as 2 to 1; for calculation we therefore adopt this ratio.

It has been shown that the 1st division has an average ascent of 14.75 feet per mile. This ascent, however, is not uniform; in several places for short distances it descends westward, some portions are level, and the ascents are at rates varying between 2.64 and 37.48 feet per mile, excepting a short piece near the foot of inclined plane. They seldom much exceed 20 feet, except for short distances. The length of grades at the higher rates of ascent is generally less than one mile, and alternate with those of medium rate; except near the inclined plane. In view of the character of this division, it is believed animal power will allow such variations as to accommodate the varying resistance, with nearly as much economy as on a uniform ascent. If we calculate on a uniform ascent of 18 feet per mile, we shall not probably vary essentially from the true economy of the case.

It has been observed, the freight is as 2 to 1 in the opposite direction, being least westward. The weight of the wagons will probably be 1/3 of the gross load; and for computation, we may assume the wagon to weigh one ton; and consequently the freight eastward will be 2 tons and that westward 1 ton.

The resistance from friction is taken at 1/10 of the gross load, the velocity being low. On a level this will require nearly 9 pounds per ton, on an ascent of 18 feet per mile gravity will be 1/10 of the load, or 7.64 pound per ton. The wagon and its freight going westward makes a gross load of 3 tons; the resistance will there-

fore be  $9 \div 7.84 \times 2 = 33.28$  lbs. To carry on a level road, a load which including wagons would be 3 tons, the resistance would be  $9 \times 3 = 27$  lbs. The road, with a few exceptions, descends eastward or is level. The ascents are small and so near the eastern termination, that, in the average, less power would be required than on a level; but we require 33.28 lbs. to move westward, after providing for varied effort by the animal. Now, as a general result, we would not expect a more equal ratio of freight in the two opposite directions than in this case, and if 27 lbs. is required on a level, we have an excess of power to provide for the load moving westward, of  $33.28 - 27 = 6.28$  lbs., and as this will return with the opposite load, we have extra power for the two directions  $= 12.56$  lbs. more than required for a level road, or 23 per cent. extra. This added to the extra curvature of 10 per cent., raises the extra traction to 32 per cent. on this section. The cost of the moving power is nearly  $\frac{1}{2}$  of the total expense, and  $32 \times .40 = 14.80$ , say 15 per cent., the cost of transportation over a level road; and  $40.25 \times .15 = 6.03$ , or equal an increase in the length of this division of 6 miles.

2d division. The total ascent westward is on the inclined planes Nos. 1 and 2; their total length is 5,160 feet, and ascend at an average rate of one in twenty-eight and three-fourths. It is obvious, the load moving westward will determine the expense of power, as that in the opposite direction on these planes will descend by its own gravity, requiring only the expense of brakemen to control its descent within a safe velocity, which may be done by a part of the drivers, whose teams could be led back by others. In moving up this ascent, a horse would require 55 per cent. of his power to overcome the gravitating force of his body; but as he would be loaded only in one direction, and the length of either plane but little exceeding half a mile, it is believed to be a fair estimate to compute, in this case, the useful effort of his power as equal what it would be on a level. We have one ton of goods and one ton of wagon, making a gross load of 2 tons moving westward. The total resistance up the plane will be 173 lbs., or 5.4 times greater than the load in the opposite direction, (3 tons gross,) would be on a level. The two planes are together 0.97 miles in length. The ascent will make the extra resistance equal  $5.23 \times .4 = 2.09$  miles.

The 3d and 4th planes descend westward; their total length is 5,100 feet, and descend at an average rate of  $\frac{1}{17.73}$ . For these planes, we must compute the power required to ascend them with the load moving eastward, which is 3 tons including wagon. The horse will require 47 per cent. of his power to overcome the gravitating force of his body up the plane; and though he will, as in the case of the other planes, be loaded only in one direction, still it is believed that 10 per cent. should be taken from his average useful effect in ascending Nos. 3 and 4. The resistance of 3 tons up these planes will be 344 lbs., equal 11.73 times greater than on a level, or including the loss in the effective power of the horse, equal 13.13 times greater. The two planes are .96 miles  $\times 13.12 \times .4 = 4.4$  miles extra length of transportation. The influence of the planes on this division increases the moving power equal to what would be required for 17 miles of level road, and taking the moving power at 40 per cent. of the total expense of freight, a fraction over 64 miles, entire cost of transportation.

3d division. Ascends eastward at the average rate of 95 feet per mile, varying from 9.76 to 52.80. The grades that have the higher rates of ascent are short, and in view of the small amount of labor required of the horses in the opposite direction, it will probably not vary materially from the truth, to compute the power at the average rate of ascent, or  $\frac{1}{11.73}$ . A load eastward is 3 tons, including wagons, and the resistance will be 58 lbs., equal 2.14 times that on a level; or for 11.25 miles, requiring extra moving power, equal what would be required for 12.82 miles on a level, or equal the total expense of transportation for 51 miles.

4th division. Is quite of an undulating character; the ascent is greatest in the aggregate in the direction of the greatest trade, but the grades have a less rate of ascent than in the opposite direction. The average ascent in the direction of the greatest trade will be a fair basis of computation for the section: This is  $\frac{1}{11.73}$ , and the resistance for 3 tons, (as before,) is 40.44 lbs. or 50 per cent. greater than a level. For 16 miles the extra moving power is equal 8 miles on a level, or equal the total cost of transportation for 34 miles nearly.

In the first division we have extra equal	6 miles.
In the second division we have extra equal	54 "
In the third division we have extra equal	51 "
In the fourth division we have extra equal	34 "
	314 "
Total length of road is	71
	— 92.12

The actual cost of transportation has been shown to be 3.96 cts. per ton per mile. To reduce this to our standard, we have the cost of transportation, exclusive of toll or profits, 3.05 cts. per ton per mile, with freight as two to one in the different directions.

By report of superintendent, the moving power cost 1.06 cts. per ton per mile.

#### Repairs.

Year, ending October, 1833,	\$444 per mile.
" " " 1834,	\$321 " "
Average for 2 years,	\$382.50.

A road constructed mostly of timber will vary much in the cost of repairs for different years, and several are therefore necessary to obtain a proper average.

Cost of transporting passengers per mile, 1.98 cts. as stated in Hazard's Register of Pennsylvania, v. 15, p. 112.

#### Liverpool and Manchester Railway.

In a statement published by Mr. Booth, the treasurer of the company, dated June 30, 1830, the expenditure up to that time, including an estimate, (the road was at this time nearly completed,) to finish some unimportant items of work, it appears the construction of the railway, exclusive of warehouses, wharfs, offices, engines, wagons, and other items not connected with the construction of the road, cost 694,595l. for 31 miles, equal  $22,406l. \times 4.80 = \$100,748$  per mile. There have, subsequently, been heavy expenditures, not embraced in the account of repairs, but we are not sufficiently advised of their object to say whether, or not, any part of it belonged to the amount of the original construction of the road.

It appears from four semi-annual reports of the directors, the expense of repairs have been as follows, to wit:

Report of July, 1832, 1st January to 30th June,	27,351 10 6
Report of January, 1833, 1st June to 31st Dec.,	5,878 4 3
Report of July, 1833, 1st January to 30th June,	6,714 9 3
Report of January, 1834, 1st July to 31st Dec.,	6,425 14 8

Total for 2 years, £27,349 8 8

Equal, for 31 miles,  $882 \times 4.80 = \$4,333$  per mile, which, for one year, is equal \$2,116 per mile, commencing about a year after the road was opened for business.

A table is given of the general expenses in the six months previous to that reported in July, 1832, in which the expenses of repairs is included with some other items. This aggregate sum is very nearly the same as reported in detail, showing there had been no material variation in repairs for the six months previous to that particularly reported.

(To be continued.)

THE STEAM CARRIAGE COMPANY OF SCOTLAND have brought an action of damages against the Trustees of the turnpike road between Glasgow and Paisley, for having compelled them to give up running on that road (after doing so with great success for several weeks continuously) by "wantonly, wrongfully, and maliciously accumulating masses of metal, stones, and rubbish, on the afore-

"Cements.—Mortar made of good lime and clean sharp sand may be successfully employed for the same purposes as Roman cement, provided it be allowed sufficient time to dry before water is permitted to rest upon it. This was mentioned many years ago by Arthur Young, in his "Agricultural Survey of Lincolnshire," and we have seen it proved in a variety of instances. In stuccoing the front of a house in or about London; for example, no builder need ever have recourse to any of the metallic cements, (including under this term Roman cement, Parker's cement, Hamblin's mastic, and all other quick-setting cements, which are only quick-setting in consequence of their containing some metallic oxide,) provided he can procure the best stone lime from Dorking or Aberthau. For our own parts, we should have more confidence in the durability of stucco so formed than in that of any of the cements. —[Mr. Loudon, Archit. Mag.]

[For the American Railroad Journal.]

*Remarks on the Substitution of Locks for Inclined Planes on Railways.*

The disuse of stationary steam power on railways has long been an object whose attainment has been anxiously desired, but hardly expected. Attention to this subject is daily increasing, as its importance is continually growing more apparent.

The efforts of ingenuity have heretofore been generally directed to improvements in the locomotive engine, by which it would be enabled to move up very considerable ascents by its own unassisted strength. In a late number of the Railroad Journal, I find an extract from a Baltimore paper, stating that an engine had been fabricated in that city able to rise on an elevation of two hundred and sixty feet in a mile, or one foot in twenty; and the belief is expressed, that the same species of engine would be capable of carrying one hundred passengers in a train of cars, up an acclivity of one hundred feet in a mile, at the rate of ten miles an hour.

This may perhaps be all accomplished, but still I have doubts as to the substantial utility of such an achievement. For the attainment of the greatest degree of economy, all the power of the engine, which may be safely exerted, should be constantly employed. But if sufficient energy is provided to rise such steep acclivities, there must be an immense superabundance and waste throughout all the other portions of the route.

In a report of the commissioners of the Liverpool and Manchester Railway, made to the House of Commons a few years since, it is stated, as the result of experiment, that an engine capable of moving thirty tons over a level track could raise no more than seven tons on an elevation of one foot in a hundred, or about fifty-two in a mile. If this be true, the same engine would be unable to draw more than three tons at the utmost, where the ascent was a hundred feet in a mile, since the load capable of being propelled would have to be diminished much faster than in a direct proportion to the degree of acclivity; and since the engine and its appurtenances occasion almost the sole expense of transportation, the cost of carrying three tons over such an undulating road would be nearly equal to the freight, on thirty tons upon a level way. The whole load which an engine can transport will be limited by what it can move over the most difficult part of the way. Now, I do not doubt but that engines may be constructed capable of raising a load on an elevation of one hundred feet in a mile; but would it not be wiser to construct the road more nearly level, so that the same engine might carry a load several times as large? Where the transportation of passengers is alone concerned, economy being of little consequence in comparison with speed, such a waste of power may be justified; but where intended principally for the carriage of freight—where the diminution of expense is the principal object, there are

very strong objections to an arrangement by which a large proportion of the propelling power lies waste and idle during the greater part of the journey, to be exerted only on the ascent of eminences.

In England, where there is much more experience than in this country, not only in the construction, but also in the operation of railroads, it is considered unwise to attempt the ascents of more than fifty feet in a mile by the sole power of the locomotive.

But it is not merely a want of power which fixes a limit to the degree of ascent practicable on railways. No matter what the ability of the engine, if the adhesion of the wheels to the rail is not sufficient to prevent them from sliding round in their places, the load cannot be moved; and this it is which, more than any thing else, renders rapid ascents impracticable. Experiments made when the wheels and rails are new, and not yet worn smooth by use, are not satisfactory upon this point, especially when it is recollected that those rails may not unfrequently be rendered slippery by ice or snow. The importance, therefore, of resorting to some other substitute for inclined planes, beside those hitherto contrived, is sufficiently evident.

An expedient of such a nature has lately received some notice, not only in the columns of this Journal, but also in those of several other public prints of this city. I refer to the railroad lock invented by Colonel Taylor. An attentive examination will, I think, convince any one, that its operation is founded upon well established principles of mechanical philosophy, and that it must prove successful.

The great object of the lock in question is to enable the locomotive engine to raise itself and all its train by its own unassisted strength, over any elevation, no matter how high, or how steep. This object is attained by a recourse to that universal mechanical principle, that what a power wants in intensity may be made up for in distance; that if it is only the half of what would be required to move a given weight on a direct application, such machinery must be interposed as that the distance through which the power moves may be twice as great as that through which the weight is raised. The merit of the invention in question consists in this: That when an ascent is to be overcome, and the power ordinarily required becomes insufficient, a provision is made by which the distance traversed by it may be any number of times greater than that ascended by the weight, so that no additional force is called for to assist the locomotive in any emergency.

This is accomplished by the agency of screws, which being moved by the power of the locomotive itself, elevate the engine and all its train perpendicularly from one reach to another. It will be readily perceived that such machinery may be interposed between the power and the load, that the distance traversed by the former, that is to say, the space through which the piston moves, shall bear any necessary proportion to that ascended by

the latter, and thus success be rendered certain.

As has been already observed, the great object to be attained in order to secure the strictest economy in transportation, is such an arrangement that the power required to propel the load may be the same throughout every portion of the route. Now suppose the road to be perfectly horizontal, and all changes of level between one reach and another to be effected by the locks in question; and suppose the machinery of those locks to be so constructed and proportioned that the same power which propels the load upon the rails should be just sufficient to raise it upon the locks, the object desired is completely attained. Not one ounce of power would lie idle throughout any portion of the route—not an ounce would be wanting. There would be neither loss nor deficiency, and the system, so far as economy of transportation was concerned, would be perfect.

Such a state of exactness would not, however, be necessary or advisable. The increased expense of grading would more than counterbalance the advantage to be gained from a perfectly level road. The power of a steam engine is not fixed and invariable. It may to a certain extent be increased without detriment, so as to enable it to rise over moderate elevations. Still it is sufficiently evident, that although it may not be practicable to carry the proposed system to a degree of absolute perfection, yet that state may without difficulty be so nearly approached as to secure the greatest advantages.

I have at this time paid no regard to the superior excellence of the lock in question, so far as safety, convenience, and economy of construction, were concerned. This might be readily shown, and in many respects will be at once perceived, without further explanation. There is every probability, therefore, that success will crown this endeavor to improve the construction of railways, and will, I trust, become an important era in the history of internal improvements.

M.

*Report of John B. Jervis, Holmes Hutchinson, and Frederick C. Mills, to the honorable the Canal Commissioners of the State of New-York:*

(Continued from the preceding page.)

*Transportation.*

The reports above referred to, embrace 4 semi-annual accounts for transportation, and one tabular view of transportation for 6 months previous, from which the following table is made.

The report of July, 1832, contains a statement of transportation for the two semi-annual terms preceding.

In the tabular account of given by the directors, the maintenance of way and rate, taxes and omnibusses are charged to transportation; but in the following table these are not included, as it is the design to exhibit the cost of transportation separate from other expenses; these items are given in the table of directors' reports, with others, but are separate in the general account.

*Report on the Progress and Present State of our Knowledge of Hydraulics as a Branch of Engineering.* By G. GENNETE, Esq., F. R. S., &c. &c. Part I.

(Continued from number 3.)

In the year 1801, M. Eytelwein, a gentleman well known to the public by his translation of M. Dubuat's work into German, (with important additions of his own,) published a valuable compendium of hydraulics, entitled "*Handbuch der Mechanik und der Hydraulik*," in which he lays down the following rules:

1. That when water flows from a notch made in the side of a dam, its velocity is as the square of the height of the head of the water; that is, that the pressure and consequent height are as the square of the velocity, the proportional velocities being nearly the same as those of Bossut.
2. That the contraction of the fluid vein from a simple orifice in a thin plate is reduced to 0.64.
3. For additional pipes, the co-efficient is 0.65.
4. For a conical tube, similar to the curve of contraction, 0.98.
5. For the whole velocity due to the height, the co-efficient by its square must be multiplied by 0.0458.
6. For an orifice, the co-efficient must be multiplied by 7.8.
7. For wide openings in bridges, sluices, &c., by 6.9.
8. For short pipes, 6.6.
9. For openings in sluices without side walls, 5.1.

Of the twenty-four chapters into which M. Eytelwein's work\* is divided, the seventh is the most important. The late Dr. Thomas Young, in commenting upon this chapter, says—

"The simple velocity of a river be the most v. improvements, from which it is exceptional. the square of a number of particles proportional to the velocity is torn asunder in a time proportionally short—for, according to the analogy of solid bodies, no more force is destroyed by friction when the motion is rapid, than when slow—but because, when a body is moving in lines of a given curvature, the deflecting forces are as the squares of the velocities; and the particles of water in contact with the sides and bottom must be deflected, in consequence of the minute irregularities of the surfaces on which they slide, nearly in the same curvilinear path, whatever their velocity may be. At any rate, (he continues,) we may safely set out with this hypothesis, that the principal part of the friction is as the square of the velocity, and the friction is nearly the same at all depths; for Professor Robison found that the time of oscillation of the fluid in a bent tube was not increased by increasing the pressure against the sides, being nearly the same when the principal part was situated horizontally, as when vertically. The friction will, however, vary, according to the surface of the fluid which is in contact with the solid, in proportion to the whole quantity of the fluid; that is, the friction for any given quantity of water will be as the surface of the bottom and sides of a river directly,

and as the whole quantity in the river inversely; or, supposing the whole quantity of water to be spread on a horizontal surface equal to the bottom and sides, the friction is inversely as the height at which the river would then stand, which is called the hydraulic mean depth." It is, therefore, calculated that the velocities will be a mean proportional between the hydraulic mean depth and the fall, or  $\frac{1}{2}$ ths of the velocity per second.

Professor Robison informs us, that by the experiments of Mr. Watt on a canal eighteen feet wide at the top, seven feet at the bottom, and four feet deep, having a fall of four inches per mile, the velocities were seventeen inches per second at the surface, fourteen inches per second in the middle, and ten inches per second at the bottom, making a mean velocity of fourteen inches per second; then finding the hydraulic mean depth, and dividing the area of the section by the perimeter, we have  $\frac{50}{20.8}$ , or 29.13 inches; and the fall in

two miles being eight inches, we have  $\sqrt{8 \times 29.13} = 15.26$ , for the mean proportional  $\frac{1}{2}$ ths, or 13.9 inches, which agrees very nearly with Mr. Watt's velocity.

The Professor has, however, deduced from Dubuat's elaborate theories, 12.568 inches. But this simple theorem applies only to the straight and equable channels of a river. In a curved channel, the theorem becomes more complicated; and, from observations made in the Po, Arno, Rhine, and other rivers, there appears to be no general rule for the decrease of velocity going downwards. M. Eytelwein directs us to deduct, from the superficial velocity,  $\frac{1}{4}$ th for every foot of the whole depth. Dr. Young thinks  $\frac{1}{5}$ ths of the superficial velocity sufficient. According to Major Rennell, the windings of the river Ganges, in a length of sixty miles, are so numerous as to reduce the declivity of the bed to four inches per mile, the medium rate of motion being about three miles per hour, so that a depth of thirty feet, as stated velocity per second, will be miles per hour. Again, all has thrice the volume of its motion is also acceleration of 5 to 3; and, as hydraulic mean depth to be one of the inundation, the increased in the ratio of 7 lination of the surface is also, and consequently velocity of from 1.4 to in agrees with Gennete,†

that a river may absorb the whole of the water of another river, equal in magnitude to itself, without producing any sensible elevation in its surface. This apparent paradox Gennete pretends to prove by experiments, from observing that the Danube absorbs the Inn, and the Rhine the Mayne, rivers; but the author evidently has not attended to the fact, as may be witnessed in the junction of rivers in marshes and fenny countries—the various rivers which run through the Pontine, and other marshes, in Italy, and in Cambridgeshire and Lincolnshire, in this country; hence, the familiar expression of the waters being overridden, is founded in facts continually observed in these districts. We have also the experiments of Brunings, in the "*Architecture Hydraulique Generale de Wiebeking*," Walmann's "*Memoires sur l'Art de construire*

les Canaux," and Fank "*Sur l'Architecture Hydraulique Generale*," which are sufficient to determine the co-efficients under different circumstances, from velocities of  $\frac{1}{2}$ ths to 7½ feet, and of transverse sections, from 1 to 18135 square feet. The experiments of Dubuat were made on the canal of Jard, and the river Hayne; those of Brunings, in the Rhine, the Wasl, and Isrel; and those of Walmann, in the drains near Cuxhaven.

M. Eytelwein's paper contains formulae for the contraction of fluid veins through orifices,\* and the resistances of fluids passing through pipes, and beds of canals and rivers, according to the experiments of Couplet, Michelotti, Bossut, Venturi, Dubuat, Walmann, Brunings, Fank, and Bidone.

In the ninth chapter of the "*Handbuch*," the author has endeavored to simplify, nearly in the same manner as the motion of rivers, the theory of the motion of water in pipes, observing that the head of water may be divided into two parts, one to produce velocity, the other to overcome the friction; and that the height must be as the length and circumference of the section of the pipe directly, or as the diameter, and inversely as the area of the section, or as the square of the diameter.

In the allowance for flexure, the product of its square, multiplied by the sum of the sines of the several angles of inflection, and then by .0038, will give the degree of pressure employed in overcoming the resistance occasioned by the angles, and deducting this height from the height corresponding to the velocity, will give the corrected velocity.†

M. Eytelwein investigates, both theoretically and experimentally, the discharge of water by compound pipes, the motions of jets, and their impulses against plane and oblique surfaces, as in water wheels, in which it is shown that the hydraulic pressure must be twice the weight of the generating column, as deduced from the experiments of Bossut and Langendorf; and in the case of oblique surfaces, the effect is stated to vary as the square of the sine of the angle of incidence; but for motions in open water, about  $\frac{1}{2}$ ths of the difference of the sine from the radius must be added to this square.

The author is evidently wrong in calculating upon impulse as forming part of the motion of overshot wheels; but his theory, that the perimeter of a water wheel should move with half the velocity of a given stream, to produce a maximum effect, agrees perfectly with the experiments of Smeaton, and others.‡

\* "*Recherches sur le Mouvement de l'Eau, en ayant egard a la Contraction qui a lieu au Passage par Divers Orifices, et a la Resistance qui retarde le Mouvement, le long des Parois des Vases*," par M. Eytelwein. "*Memoires de l'Academie de Berlin*, 1814 and 1815.

† Hence, if  $f$  denote the height due to the friction,  $d$  = the diameter of the pipe,  $W$  = a constant quantity,  $WW$

we shall have,  $f = V^2 \frac{a}{d}$  and  $V^2 = \frac{f d}{a}$ . But the height employed in overcoming the friction corresponds to the difference between the actual velocity and the actual height; that is,  $f = h - \frac{V^2}{2g}$ , where  $h$  is the coefficient for finding the velocity from the height.

Hence we have,  $V^2 = \frac{h d - \frac{V^2 d}{2g}}{a d + d}$  and  $V = \sqrt{\frac{h d}{a d + d}}$ .

Now Dubuat found  $h$  to be 6.6, and  $a$  52 was found to be 0.011, particularly when the velocity is between six and twenty-four inches per second. Hence we have,

$V = \frac{43.6 d}{0.011 d + d}$ , or  $V = 43.6 \sqrt{\frac{d}{d + 41 d}}$ , or more accurately,  $V = 50 \sqrt{\frac{d}{d + 30 d}}$ .

‡ The author of this paper has made a great many experiments on the maximum effect of water wheels;

\* See Nicholson's translation of Eytelwein's work.

† See my "*Experiments on the Friction and Resistance of Fluids*," Philosophical Transactions for 1821.

‡ See Nicholson's Journal for 1802, vol. iii., p. 31.

† Experiences sur le Cours des Fleuves, ou Lettre a un Magistrat Hollandais, par M. Gennete. Paris, 1760.

The author concludes his highly interesting work by examining the effects of air, as far as they relate to hydraulic machines, including its impulse against plane surfaces, on syphons and pumps of different descriptions, horizontal and inclined helices, bucket wheels, throwing wheels, and, lastly, on instruments for measuring the velocity of streams of water. A very detailed account of the work was given in the *Journal of the Royal Institution*, by the late Dr. Young. But it is due to MM. Du-buat and Prony to state, that M. Eytelwein has exactly followed the steps of these gentlemen, in his "Theory of the Motion of Water in Open Channels."

[To be continued.]

[From the London Mechanics' Magazine.]

**Gun with a Revolving Breech—Simple Mode of Increasing the Tractive Power on Roads—Relief-wheels for Common Road Steam-Carriages.**

Sir: The following matters are submitted for insertion in your truly valuable publication, should you deem them deserving a place in it.

I am, Sir, your obedient servant,

ROBERT CAREY,  
Rector of Donoughmore.

1. The first invention to which I would call your attention is a gun with a revolving breech, containing seven chambers, brought in succession into position, by the single movement of elevating the hammer. I sent it to the exhibition of Irish Manufactures and Inventions, held at the Royal Dublin Society, in May, 1834, where it still remains. It is thus described in the Dublin Evening Packet, of the 22d of May: "In our last notice of this exhibition we described a gun with a revolving breech, capable of being discharged seven successive times within a space of from 25 to 30 seconds; we have just learned that the inventor is a clergyman, living in the county of Tipperary, and that the gun was manufactured in the town of Clonmell." I would here observe, that it has been suggested to me by military persons that the principle of the above invention would apply with great effect to cannon.\*

2. I would in the next place submit a project directed to the increase of power applied to draught.

The means which I would suggest for the attainment of this object are a new formation of road, by which wheels of any diameter, that it may be found convenient to use, are rendered applicable to draught, without destroying the proper direction of the line of traction. I propose to give what I shall term the power-road (or that on which the power moves, whether it be steam or otherwise,) an elevation above the waggon-road (or that on which the train of carriages moves,) proportioned to the magnitude of the

wheels which it may be found most advantageous to use. Assuming that the power attained from the application of wheels of different magnitudes, moving on ordinary roads, varies in the direct ratio of their semi-diameters, an elevation of three feet in the power-road would double the power, inasmuch as it would render applicable wheels of double the diameter that would apply with effect on an ordinary road. I am aware the advantage obtained on a railroad, by the application of this principle, is not so considerable; I calculate that the comparative powers of wheels of different magnitude, on a railroad, vary as the square roots of the semi-diameter of the wheels. An obvious advantage, exclusive of the increase of power, resulting from the above construction of road, would be its rendering an upset impossible.

3. The next project I would submit is directed to obviate an inconvenience (much dwelt on in a late number of your publication,) resulting to carriages impelled by steam, and moving on common turnpike-roads, from the inequalities or ruts of unavoidable occasional occurrence in roads composed of ordinary materials. I would have each axle furnished with two wheels additional, and exterior to the main wheels, and of somewhat smaller diameter. These additional I shall term relief-wheels. The effect of this contrivance must, I conceive it is obvious, be, to relieve the carriage from any shock from inequalities in the road, except when a depression or rut presents itself at the same moment to a main wheel and corresponding relief-wheel, which, it is obvious, except on roads in total disrepair, would be of extremely rare occurrence.

I beg to apologise for the extent to which this communication reaches, and am, Sir, your obedient servant,

R. C.

Donoughmore Glebe, Clonmell,  
25th Jan., 1835.

[From the Journal of the Franklin Institute.]

**List of American Patents which issued in September, 1834.**

1. For a Perpetual Shoe Bench; Samuel Haynes, Malden, Middlesex county, Massachusetts, September 1.
2. For an improvement in navigation, called the Cylinder Boat; Amos Kendall, city of Washington, District of Columbia, September 2.
3. For a Thrashing Machine; Israel Lukens, Upper Dublin, Montgomery county, Pennsylvania, September 2.
4. For an improvement in the application of steam to the purpose of cooking, called the Steam Baker; Charles F. Wilcox, Springfield, Hampden county, Massachusetts, September 3.
5. For machinery for Cutting Crackers; Lucius Kirtland, New Haven, New Haven county, Connecticut, September 4.
6. For an improved press, for Pressing Cheese; Elijah Barnes, North Brookfield, Worcester county, Massachusetts, September 5.

7. For a machine for Hulling Barley; Henry Handschey, Bridgeville, Muskingum county, Ohio, September 5.

8. For Wheels for Carriages, &c.; Barney Ruggles, Warsaw, Genesee county, New-York, September 8.

9. For a Shoe for Mill Cans; James Dennis, Providence, Rhode Island, September 8.

10. For a Circular Saw Mill; John Penman, Charlotte, Muhlenburg county, North Carolina, September 9.

11. For Lessening Friction, by friction rollers; Isaac Clowes, Norfolk, Norfolk county, Virginia, September 9.

12. For improvements in Locomotive Engines and Cars, for Railroads; Matthias W. Baldwin, Engineer, Philadelphia, September 10.

13. For a Brick Machine; Cyrus Chaney, North Prospect, Waldo county, Maine, September 11.

14. For a Stove; James Wilson, city of New-York, September 12.

15. For an improvement in the Horse Collar Block; Dyer Cleaveland, Owego, Tioga county, New-York, September 13.

16. For a Relief Bedstead, for the use of invalids; David Anthony, Adams, Berkshire county, Massachusetts, September 13.

17. For a new Material for Stuffing Mattresses; Elias Howe, Cambridge, Middlesex county, Massachusetts, September 13.

18. For an improvement in the construction of Water Cisterns; Obadiah Parker, Syracuse, Onondaga county, New-York, September 15.

19. For an improved Re-action Water Wheel; John L. St. John, Canajoharie, Montgomery county, New-York, September 16.

20. For a Handling Machine, to be used in the manufacturing of Leather; William G. Waterman, Sullivan, Madison county, New-York, September 16.

21. For an improvement in the form and construction of Gridirons; Fenner Bush, and Linus Pratt, Meriden, New-Haven county, Connecticut. First patented July 21st, 1832. Patent surrendered, and re-issued upon an amended specification, September 17.

22. For a Straw Cutter; Nimrod Murphy, Nashville, Davidson county, Tennessee, September 17.

23. For Sun Dials of Cast Iron; Herman M'Cluer, Hamburg, Erie county, New-York, September 17.

24. For a Horse Power; Sewall Gleason, Westville, Franklin county, New-York, September 18.

25. For a Rotary Steam Engine; William Sutton, Geneva, Ontario county, New-York, September 18.

26. For a Churn; Adna L. Norcross, Hallowell, Kennebec county, Maine, September 19.

27. For Shears for Cutting Metal; George Christian, Mentz, Cayuga county, New-York, September 20.

28. For an improvement in the Forcing Pump; James D. Egbert, Lansing, Tompkins county, New-York, September 22.

29. For a Horse Power; Silvanus

\*but the recent experiments of the Franklin Institution, made on a more magnificent scale, and now in the course of trial, eclipse every thing that has yet been effected on this subject. See also Poncelet, "Memoire sur les Roues Hydrauliques," and "Anbes Courbes par dessous, &c." 1827.

\*We should be glad to receive from our worthy correspondent a more particular description of this ingenious invention. A drawing is also very desirable.—[Ed. M. M.]

#### ROTARY STEAM ENGINE.

The following inquiries have been addressed to Mr. N. Felt, who has recently substituted one of Avery's Rotaries, for a common high pressure piston engine, in his saw-mill, in Clay, to which the answer annexed has been furnished. We recommend the correspondence to the attention of machinists.

We extract the inquiries from a letter to Mr. F. from E. Lynds & Son.

"1st. Have you made any alterations in your boiler, in any form or manner, since putting the rotary in use, so as to afford more steam with less fuel?"

"2d. Is there any difference in the amount of fuel required to perform an equal amount of labor with either of the engines? If so, which requires the least, and what is the difference in the quantity used?"

"3d. Does the rotary engine do more or less work, in the same time, than the piston engine? What is the amount of difference?"

"4th. Which engine do you conceive to be the most simple in its construction, and in its application to any mechanical purpose the most natural? Also, which is kept in repair with the least expense?"

"5th. If you were to put another mill into operation, which engine would you prefer; and which do you think the most valuable for any mechanical purposes?"

From Mr. Felt, to Messrs. Lynds.

"Clay, May 1, 1835.

"GENTLEMEN,—It is with pleasure I comply with your request in giving my opinion (founded upon practice and short experience,) in relation to the difference between the former High Pressure and Avery's Patent Rotary Engine, which I now have in operation in my saw-mill.

"In answer to your first question, I would say I have made no alteration in my boilers or arches.

"2d. As to the amount of fuel required, I am not able to answer precisely, but am sure the rotary does not require more than two-thirds the quantity to put it in operation the piston engine required.

"As to the amount of business performed, the rotary will do double the amount of the piston engine in the same time. So far as I

am acquainted with the two engines, I consider the rotary the most simple in its construction and application to mechanical purposes, and I think is kept in order with the least expense. With the experience I have with the two engines, I should prefer the rotary for any mechanical purposes whatever.

"Respectfully yours,

"NORRIS FELT.

"Elam Lynds & Son."

BROOKLYN—Our Sister City.—The Brooklyn Evening Advertiser contains the following remarks:—

The public exercises of the Brooklyn Lyceum were closed for the season on Friday evening. A lecture on the *Improvement of Brooklyn*, was given by Major Douglass, in which were set forth the advantages with which we have been favored by nature and circumstances, especially as to location, prospect, &c.—advantages which, if early improved, and on an enlarged and liberal scale, would make this the most splendid and attractive city in the country, if not in the world; but which, if neglected, may compel us to take the place of humble mediocrity, or perhaps debasement. Several particulars were enumerated, which deserved immediate attention; among which was a proper arrangement of the City Plot. On this, the lecturer said depended convenience, health, and beauty. A brief view of the original plan, subsequent alterations, and present arrangement of some of the European cities was given, particularly Paris, which at first occupied only the island upon which the Cathedral now stands; and it was thence argued that a predetermined plan, if properly matured, was preferable, even on the score of economy, to one that should be subjected to the particular interests or caprice that might prevail at different periods; and it was intimated that the same exercise of authority and amount of expenditure which were required to bring the plan of Paris to its present state of perfection, would hardly be submitted to in this country. A fixed adherence to straight lines, it was contended, was opposed to convenience, economy and good taste. The city of Philadelphia was instanced; a part of Market street was the great centre of business, with respect to which, Fairmount and Kensington were situated diagonally. Suppose, according to the present rectangular arrangements of the streets, 300 horses are required to be employed in transportation between the centre of business and the two places named, one third of the number might be dispensed with if the communication were correct. The preservation of elevations and depressions was urged as indispensable both to health and beauty. The present dead level of the city of New York was often spoken of by foreigners and others as a great defect, and they could hardly be made to believe that elevations once existed, and that they were all given to the destroyer. The proper graduation of streets, the laying out sites for the public buildings and public walks, the necessary damage, &c., were successively touched upon, and due attention to them urged. The improvements of the Heights, which had become almost as noted as the famed Cliffs of Dover, or (the lecturer was about to say) the Peak of Teneriffe, was considered the first object in the embellishment of the city; all the projected plans for regulating and beautifying these grounds, to which reference was made in this paper a few days since, was briefly explained. Our external intercourse was next adverted to. A direct communication, with Boston, by means of a railroad across the Island, and with Philadelphia, by means of steamboats, &c., was deemed feasible and of much importance. The intercourse with New York it was thought, would soon render necessary some other facilities of passage than the ferries afforded. It was even now often rendered difficult, if not dangerous, to the ladies and to the aged, by the crowded state of the boats, and of the avenues leading to them. A bridge across the river had been at one time in contemplation, but (the lecturer said) from the attention which he had given to the subject, he was convinced, that though such a project might not be impracticable, it could not be undertaken to any good purpose. He had no hesitation in saying, however, that a safe and easy communication, by means of an arch, or tunnel (if we mistake not,) was not only possible, but perfectly feasible.

THE ERIE CANAL.—The following important act was passed by the late Legislature, and a meeting of the Canal Board, with reference to the gigantic work therein contemplated, is advertised for the 30th June:—

An Act in relation to the Erie Canal, passed May 11, 1835.

*The People of the State of New York, represented in Senate and Assembly, do enact as follows:*

§ 1. The canal commissioners are hereby authorized and required to enlarge and improve the Erie Canal, and construct a double set of locks therein, as soon as the canal board may be of opinion that the public interest requires such improvement.

§ 2. The dimensions to which the canal and locks shall be enlarged shall be determined by the canal board.

§ 3. In passing cities or villages and at other places, an independent canal may be constructed instead of enlarging the present works, if the canal board shall decide that the public interests will be thereby promoted. In all cases, regard shall be had in the location, to the relinquishment of damages, and to gifts, grants and donations; but nothing in this section shall authorize the board to abandon the present canal through cities or villages, where an independent canal may be deemed advisable.

§ 4. It shall be the duty of the canal commissioners to alter and arrange the present feeders, and to construct such additional feeders and other works as they may deem necessary for supplying the enlarged canal with water.

§ 5. In the construction of the several works authorized by this act, the canal commissioners shall have and exercise all the powers and privileges granted to them by the ninth title of chapter ninth of the first part of the revised statutes: And the said ninth title, so far as it may be applicable, shall apply to the works hereby authorized.

§ 6. The cost of constructing, completing, and maintaining the works authorised by this act, shall be paid by the commissioners of the canal fund out of any moneys which may be on hand belonging to the Erie and Champlain canal fund; but the accounts and expenditures under this act shall be kept separate and distinct from the accounts and expenditures for the ordinary repair and maintenance of the Erie canal.

§ 7. The eighth section of the act entitled "an act to provide for the improvement of the canals of this state," passed May 6, 1834, is hereby repealed.

§ 8. The commissioners shall report to the legislature their proceedings under this act, within thirty days after the commencement of each session.

§ 9. After the year one thousand eight hundred and thirty-seven, the expenditures by virtue of this act shall be so limited as to leave from the canal revenues without reference to auction and salt duties, an annual income to the State of at least three hundred thousand dollars, over and above all ordinary repairs and expenditures on the Erie and Champlain canals.

§ 10. No further expenditures shall be made pursuant to the provisions of this act than are necessary to construct the additional locks and works connected therewith, to enlarge the canal in the vicinity of said locks, so far as may be necessary to facilitate the passage of boats through the same, and for the purchase of such lands and the extinguishment of such claims for damages, as the commissioners may deem it expedient to secure and extinguish, until a sufficient sum shall have been collected and invested from the canal revenues fully to discharge the Erie and Champlain canal debt.

§ 11. This act shall take effect on the passage thereof.

[From the Albany Journal of last evening.]

CANAL BOAT SUNK.—A canal boat belonging to the Troy and Erie line, with thirty-five tons of merchandise, was last week, by an unavoidable accident, sunk, a few miles west of Schenectady. Much of the freight being of a perishable character, the loss, we regret to learn, will be considerable. It is fortunate, however, for those who owned the goods, that the proprietors of the line which shipped them, are abundantly responsible, and will pay the entire loss as soon as the amount shall have been ascertained.

**LONG ISLAND RAILROAD.**—We learn that nearly two millions of Dollars were subscribed for the Stock of this Company, being an excess of half a million over the capital. The books were also opened in Kings, Queens and Suffolk counties, where it is supposed that upwards of half a million more of Stock will be subscribed. It is certain therefore, we presume, that this work will be speedily completed.

**AUBURN AND SYRACUSE RAILROAD.**—Extract of a letter from Auburn, dated May 6:—

"Yesterday the Engineer, Mr. Johnson, returned here, and is very favorably impressed from the experiment made in running the first line. He made the distance 26 1-2 miles—at no place a declivity of more than 31 feet to the mile. The ground is feasible and the surface favorable the whole distance, and the work can be accomplished at a less expense per mile, than the Utica and Schenectady Railroad. You are aware that this is necessarily a part of the great railroad which will be continued from Utica to Lake Erie, but you may not know, that the charter confers the privilege of transporting goods, as well as passengers."

**BUFFALO AND DUNKIRK.**—On the 8th of April, Dunkirk, the proposed termination of the New York and Erie Railroad, was free from ice. On the 8th of May only, as will be seen by the annexed article from the Buffalo Evening Advertiser of that date, was the Buffalo harbor free from ice. A difference of one month!

[From the Buffalo Commercial Advertiser.]

Our Marine List affords a gratifying evidence, that the siege has at last been raised which has for months so effectually embargoed our steamboats, brigs, schooners, &c. Last evening, the steamboat Ohio made a demonstration against the besieging enemy, and ascertained the practicability of a passage, and this forenoon a gallant squadron of between thirty and forty sail, left port in fine style, before an easterly breeze.

Several arrivals have already been made, and we may expect a fleet of the canvassed winged messengers of commerce, with the first favorable wind.

**Erie Canal.**—We understand that about two hundred boats have been detained for a day or so, at a section of the Canal about eight miles east of Lockport, in consequence of the water having been drawn off from that portion for the purpose of making repairs at a spot where a breach was apprehended. We are informed by a gentleman arrived this morning from Lockport, that the Superintendent stated the repairs would be completed to-night, and the water again be let in to-morrow morning.

[From the Buffalo Commercial Advertiser, May 7th.]

The steamboat Sandusky, which started from the landing at Black Rock yesterday, on her return trip to Detroit, was surrounded by the floating ice in the river, and finding herself unable to force her way against the overwhelming power of the descending masses, was carried down as far as the head of Grand Island, where she brought up, with the loss of both anchors. She last evening proceeded on her way up the Lake.

**A Bull Fight with Steam.**—A few days since, as the locomotive steam engine was passing along the Columbia Railroad, the engineer espied a noble bull driving across the field, apparently to give battle to the machine. He was coming at the top of his speed, his tail stuck right into the air, and his head down, as if for immediate attack. As the bull errant rushed onward, the director checked the car, and received the blow upon the front wheel.—The animal recoiled several steps—the puffing of the steam pipe seemed to challenge him to a second onset, and on he came, bellowing and tearing up the earth, while his eyes seemed to shoot forth baneful fire. The engineer thought that his safety consisted in moving—he therefore put on the whole head of the accumulated steam, and the car started like the wind. The enraged beast struck short of his aim, he missed his footing, and rolled down a high embankment, to the infinite gratification of those who had watched his behaviour, and to the glory of the engineer.—[U. S. Gazette.]

**Steam Engines.**—Among the contracts which Mr. Philips, one of our Engine builders, is now filling, (says the Wheeling Gazette) is one from Cheraw, South Carolina, for an engine to be used on the Pee Dee river. What a train of thought is here opened to the mind;—a town in the West, which a few years ago contained but a handful of inhabitants, now furnishing steam engines to the southernmost parts of this wide union! The one spoken of can be sent to its place of destination either by way of New Orleans or Baltimore. If by the former, the freight will be half a cent per pound—insurance one per cent, on the cost; if by Baltimore, it will be taken from here in wagons on the national road, at a charge of one cent per pound—no insurance. The whole cost of delivering it in Cheraw, it is supposed, will be 400 dollars, making the cost of the engine there about four thousand, and saving to its owners from 500 to 1000 dollars over one obtained from the Atlantic workshops.

**Steamers to New York.**—We understand that Dr. Church, of this town, has recently proceeded to Liverpool with models of his engine and boiler, for the purpose of submitting them to several eminent practical engineers of that place; and we are informed that so decided is the opinion there of their applicability to marine purposes, that a company is in course of formation to establish a line of steam packets, to be worked by them between that port and New York, and that it is confidently expected the passage will be made in ten or twelve days.—[Birmingham Gaz.]

**Improvements in Greece.**—An iron Railway has been contracted for, by the Greek government, with the banker Feraldi, to run from Athens to the Piræus. Shade of Themistocles, look down!

**New Invention.**—Capt. E. Larkin of St. John, has invented a machinery, simple in its construction, and that can at a very small expense, be attached to the rudder of any vessel, that will on a dial at the rudder head, show the distance the ship has sailed and only the actual distance, for if the ship should at any time go astern, the distance so gone astern is taken off the dial, and the true distance gone ahead only is shown. Should it answer the purpose anticipated, it will be a great benefit gained in navigation, as at times it is of the greatest importance to know the distance sailed; for instance, having a given distance to run in a fog at night, it may be done with safety—this machinery giving the true and absolute distance, which has not yet been ascertained with certainty by any method, with the simplicity of this invention; as much depends in the usual method on judgment, the steadiness of the wind, and the state of the atmosphere acting on canvass having in ordinary cases great effect on the rate of sailing, in both of which cases the judgment is very liable to error; this machinery invented and exposed to the action of the wind, instead of the water, would at any time with equal accuracy give the velocity of the wind; the neatness and compact state of the invention, does much credit to Capt. LARKIN's ingenuity and mechanical talent.—[St. John. N. B. Courier.]

[From the New-England Farmer.]

**Manufacture of Axes by New Modes.**

Mr. Fessenden,

Dear Sir: If you think it an object, as I do, to show the ingenuity of Yankees in competing with foreign nations by their inventions and labor-saving machines, the following is at your service. It will afford new evidence of the onward march of improvement.

WILLIAM KENNICK.

Being lately at Douglas, Mass., I was invited by my friend, Griffin Clark, Esq. of that place, to visit the Manufactory of Axes, belonging to Messrs. Hunt & Co. At this establishment, about 500 axes and hatchets are manufactured in a day, of all descriptions, and of the most beautiful and perfect workmanship, and chiefly by a new mode. Besides adzes, and a variety of other species of edge tools, I noticed the Pittsburg broad-axe; it is not deep, but the broadest of all I have ever seen; the edge straight, and about sixteen inches in its width; its form resembles the ship-carpenter's axe,

The Kentucky axes differ from our chopping axes, only in being heavier, and having a very long bit. The chopping axes and all of larger size are formed in the usual way by doubling the iron; but all of a smaller description are formed by a new and more expeditious mode. Bars of cold iron, about an inch thick and four inches wide, more or less, according to the size of the intended axe, or hatchet, are cut into suitable lengths with ponderous shears.

These pieces being cast into the forge and brought to the required heat, are cleft at one end, and into this cleft a tongue of cast steel is inserted; then being again heated, the complete union of the iron and steel is effected with the hammer. These being subjected anew to the fire, are laid on edge in a mould, and a single and powerful blow, or pressure of an engine, completes the profile of the small broad-axe or hatchet, and this blow being repeated a second time, renders the outline still more perfect. They are next transferred to another engine, furnished with a die; in this the axe is laid, and a heavy weight of iron similar in size to those employed in driving piles, being drawn up suddenly by water power, completes the form of the axe by its fall.

Another engine is about going into use, which will give to the rough and oblong section of a bar of iron the form of a perfect and beautiful axe or hatchet at a single and instantaneous operation. Thus are these instruments formed; but the eye for the insertion of the handle is made by boring through the cold and solid iron. The axe being fixed in, a firm position above, a vertical drill of species of auger perforates them from below. This auger has a three-fold motion. First, a revolving motion on its own centre. Second, it moves in an orbit, which is that of a very eccentric ellipsis, corresponding with the form of the eye. Third, a vertical or upward motion at intervals, and at each time it has completed a revolution in its orbit.

An axe is bored in about twenty minutes; and one man will attend to twenty-five augers or axes; and another man is sufficient to sharpen the drills or instruments for the same.

Respectfully, your friend and obedient servant,  
W. K.

**WHEAT CROPS DESTROYED BY FIELD-MICE IN FRANCE.**—From Angerville, it is stated that the ten bad crops which have occurred during the last fifteen years have almost ruined our cultivators, and have caused many farms to be tenantless, the occupiers returning them on the hands of the landlords as the leases fall in. One proprietor alone in this district, has now five or six farms in this predicament. The cause of all this distress is attributed to the field mice. They devastate every spot, and this year they have invaded fresh districts, and some growers have delayed sowing their wheat till spring, there being no chance of protecting it from these vermin; and in such cases the mice have forsaken the fields where they could not find subsistence, to prey on the seed in situations where such precaution had not been used.

**VALUE OF HOPS IN DISEASES OF THE SKIN.**—One of the best external applications for many eruptive diseases of the skin is a strong decoction of Hops, in which the limbs or other affected parts are to be bathed several times a day. The decoction should not be used until it has become perfectly cold. In bad ulcers of the leg, the most satisfactory results have been repeatedly realized from this simple preparation.—[Med. Intel.]

[From the Journal of the Franklin Institute.]

#### DETECTION OF ADULTERATIONS IN FLOUR.

M. Dubuc, senior, of Rouen, has applied himself with success to the detection of farinaceous mixtures in wheaten flour. The principal substances with which flour is adulterated are potato starch, a fecula; beans, barley, chalk, plaster of Paris, &c. An extract from his memoir is published in the last Bulletin of the Society of Encouragement, from which the following is taken.

There are two methods of detecting adulterated flour, mechanical and chemical. In France the adulteration is principally with potato starch, as it renders the bread whiter and heavier. If there be more than ten per cent. of potato starch, it may be detected by the naked eye, or with the aid of a magnifying glass; the fecula is whiter, the particles are angular, and reflect the rays of light, like minute crystals. To render the discovery more easy, M. Dubuc dries the suspected flour in a sand bath, at 100° to 110° of Fahrenheit; and then, with a good magnifying glass, so small an adulteration as five per cent. may easily be detected.

But if the miller has been cunning enough to grind the potato starch with the wheat, other means of detection must be had recourse to.

The first is, from the great difference between the specific gravity of wheat flour and potato starch.

The second is, that flour contains a certain per centage of *gluten*, and the starch does not contain an atom of gluten.

**First Method.**—A vessel that will contain one pound of flour, gently pressed down, will contain a pound and a half of *fecula*; from these data the relative portions of flour and fecula, in any parcel of flour, may be easily ascertained very near the truth.

**Second Method.**—The best flour contains about twenty per cent. of gluten, and, as we have stated, the starch not an atom.

**Experiment.**—Take five ounces of pure wheat flour, and two ounces and a half of warm water; mix and work it well for about ten minutes; the paste will be firm and elastic. Let a little warm water fall continually upon it, while you continue to knead it; by this means, all the starch and saccharine mucilage will be extracted. The operation is finished when the water flowing from it ceases to be white; what remains is gluten, the weight of which will be about one ounce. If the flour be adulterated, the paste will be more liquid, less cohesive, and less elastic, and an intelligent baker will soon be able to discover to what extent the flour has been adulterated, from the appearance of the paste, &c.

Such are the mechanical means that may be employed with success.

**Employment of Chemical Agents to detect Frauds in Flour.**—It will be well to begin with, that wheat flour is an animalized nitrogenator, (*matiere animalisee azotee*), and that, on the contrary, fecula, or the starch extracted, pure from cere-

als, is entirely of a vegetable nature: from this difference results the varied effects of the re-agents employed.

The three chemical tests which have been found best for general use, are nitric and muriatic acid, and the liquid nitrate of mercury, (*deuto nitrate*.) Their chemical effects on flour and fecula are as follows:

1. Nitric acid has the property of coloring wheat flour of a fine orange yellow, whereas it neither affects the color of fecula nor starch.

2. Pure muriatic acid colors good wheat flour of a deep violet, but dissolves fecula and starch, and forms with it a light, colorless, viscous fluid, decomposable by alkalies.

**Experiments with Nitric Acid of 40°.**—Take 100 grains of pure wheat flour, pour on it 100 grains of nitric acid, (*aqua fortis*), in a small earthen or China cup, stirring it with a glass tube, it will heat a little, and in a few hours it will change color from yellow to a fine orange color.

Take 100 grains of fecula, and pour on it 100 grains of nitric acid; heat it in every respect the same as above, but no caloric will be evolved, and the mixture will not change color.

Take of flour 80 grains, and of fecula 20 grains, and of acid 100 grains; mix well; the color will now be much paler, and of a light citron color. Take 50 grains of flour, and 50 grains of fecula, and 100 grains of acid; mix well; the color is now much paler than before, so that, with a little practice, the quantity of fecula may be detected by the greater or less intensity of colors.

**Experiments with Muriatic Acid of 21 Degrees of Strength.**—Take of wheat flour and acid, each 100 grains; mix well; the color will become at first red, then violet, and finish by becoming of a beautiful indigo color. This operation is accelerated if a gentle heat be applied.

Take 100 grains of fecula, and 100 grains of acid; the mixture is at first of the consistency of paste, and then becomes liquid; the fecula is dissolved, and the solution *colorless*.

On varying the proportions of flour and fecula, we shall soon be able to ascertain the quantity of fecula in a sample of suspected flour.

**Experiment in the Liquid Nitrate of Mercury.**—Take of flour and nitrate each 100 grains; mix well with a glass tube or rod. The paste will at first be of a pale citron, then reddish, and in three hours will become a full red. The color is permanent.

Take 100 grains each of fecula and nitrate; they will not combine, nor will the color of the fecula or starch be acted upon.

By mixing flour and fecula in different proportions, and observing the colors, we may soon be able to detect the proportions in which flour is adulterated by fecula or starch.

It may also be observed, that fecula absorbs less water than flour, which affords a ready means of detection.

The adulteration with bean or pea flour may be detected by pouring boiling water upon it, which develops the peculiar smell of these two substances.

We may add, that the adulteration with chalk, or gypsum, may be detected by pouring a diluted acid on the suspected flour, as an effervescence will take place, and carbonic acid gas be disengaged.

#### Experiments in Assaying.

To the Editor of the Mechanics' Magazine:

SIR,—I am engaged in the iron trade, and had an intention to erect a blast furnace a few years since for smelting iron from the ore of a new bed, and was naturally desirous, before doing so, to ascertain as nearly as possible what were its qualities. I therefore commenced assaying it and some other ores found in the neighborhood; but I soon concluded that the methods described in the books, which direct the use of "calcined borax, pounded bottle glass, chalk, &c." were not suited to the object which I had in view, namely, to ascertain what kind and quantity of iron might be expected from the ore when used in the large way in the blast furnace. I therefore laid those articles aside, and continued my experiments with the same materials which I expected to use when working the furnace; and the following memoranda show some of the results obtained.

December 2—Roasted 3 specimens of brown hematite ore:

No. 1	lost in weight	16.01	per cent.
2	do.	18.52	do.
3	do.	14.58	do.

Assayed 2	14	3	of the above ore with
	8	0	of limestone,
	8	0	of clay,
	10	0	of pounded charcoal.

The above, after being three hours in the furnace, produced 1 oz. 9 dwts. 9 gra. of metallic iron, equal to 54.27 per cent. The iron was tough, like the iron from a blooming fire.

Note—This experiment was not very satisfactory, on account of the iron not forming a good button at the bottom of the crucible.

No. 5. Assayed—

1	15	0	of roasted ore, with
	5	12	of clay limestone,
	5	12	of clay,
	7	6	of pounded charcoal,
	13	4	metallic iron.

The above produced, after 3 hours' heating, 1 oz. 13 dwts. of iron, which, after deducting the 13 dwts. of metallic iron added to the charge, left 19 dwts. 20 gra. for the produce of the ore, equal to 56.66 per cent. The slug was rather tough and infusible; the specific gravity of the iron, 7.238.

The foregoing, I dare say, is as much as you will desire at one time. Should yourself, or any of your readers, desire more, I shall be happy to furnish you with further extracts, and remain,

Your obedient servant,

J. D. W.

Vergennes, April 13, 1835.

NEW-YORK AMERICAN.

MAY 9-15, 1835.

LITERARY NOTICES.

THE WORKS OF MRS. SHERWOOD, vol. IX., uniform edition. New York, HARPER & BROTHERS.—We have in this volume the commencement of the *Lady of the Manor*—the well known series of conversations on the subject of Confirmation—printed with all the accuracy of the preceding volumes.

THE NATIONAL CALENDAR AND ANNUAL OF THE UNITED STATES, for 1835: vol. XIII. Washington, PETER FORCE.—This annual becomes every year more valuable, and more explanatory of the progress of the government, in the creation of offices, if nothing else. It has almost all the information contained in the famous "blue book"—which is only for members of Congress—besides the annual reports from the public departments, the tariff, &c. &c. Americans who interest themselves in public affairs, and all Americans going abroad, should have this Calendar.

THE ELEMENTS OF GREEK GRAMMAR, by R. VALPEY, D.D. F. A. S., with additions by C. ANTHON, Jay Professor of languages in Columbia College.—New York, W. E. DEAN. This is the tenth edition of this Grammar—a symptom that amid the march of mind projects, which sometimes threaten to overthrow the classics, the study of Greek yet holds its way.—The first edition was published about five years ago.

THE FLOWER GARDEN OR MONTHLY CALENDAR OF PRACTICAL DIRECTIONS FOR THE CULTURE OF FLOWERS, by MARTIN DOYLE, author of "Hints to small Farmers," "Practical Gardening," &c.—1st American edition, adapted to the climate of the United States, with notes, &c., by L. D. GALE, M.D. Prof. of Chemistry, &c.; New-York MOORE & PAYNE. This is a pretty, and as far as we can judge, a useful and judicious guide to those who love Flowers, and have the taste to cultivate them. It is plainly and perspicuously written, and adopts the form of a calendar, giving under each month the duties of that month, and the flowers to which care should be given.

THE NORTH AMERICAN ARITHMETIC.—Part third—for advanced scholars—by FRED. EMERSON, late Principal in the department of arithmetic of the Boylston School, Boston. Boston, RUSSELL, OGDEN & METCALF. W. F., COLLINS & HANWAY.—The testimony borne to the excellence of this treatise, by those most competent to form a right judgment, the Professors of various colleges—and teachers of schools—who unite in praising its perspicuous arrangement, and clear elucidations—dispense us from saying any thing further than to express our full assent, so far as we have found leisure to examine the work, to those praises. It should be added, that the public School Committee of Boston, upon the application of the masters of the schools, have discontinued the books on arithmetic previously in use, and substituted these—viz: parts I., II. and III. of Emerson.

THE ALEXANDRIAN, Nos. 1 to 15;—price 6 1-4 cents each, being a republication of valuable Literary and Scientific works; New York, WM. PEARSON.—Assuredly, if readers do not multiply in these days, it is not from want of temptation, or opportunity, for the best works are thrown, as it were, at their feet, for comparatively a song. Here, for instance, we have bound up in a handsome volume, of some 450 pp. double columns and small type, fourteen numbers of the Alexandrian, containing both series' of D'Israeli's Curiousities of Literature, and his Essay on Literary Character;

the whole for the sum—in numbers—of eighty-eight cents! In No. 15 *Combe's* capital book on the Constitution of Man, &c., is commenced.

NEW YORK AS IT IS IN 1835. New York. J. DISTURNELL.—A pretty little volume, containing a notice of all the institutions, literary and commercial, of this great city—a general description of the city and its environs, with maps, &c.—making a useful pocket companion and book of reference.

TOUGH YARNS, a series of Naval Tales and Sketches, by THE OLD SAILOR—author of *Greenwich Hospital*, &c. 2 vols. Philadelphia. E. L. CAREY & A. HART.—Our taste does not lie this way it may be—or perhaps because it has been over exercised by the multiplicity of sailor stories—but the fact is, we do not much admire these "tough yarns," though they are faithful delineations enough, we dare say, of the life and incident<sup>s</sup> they purport to describe. They lack interest, however, after Capt. Marryatt's stories.

THE HIGHLAND SMUGGLERS. By the Author of the *Kussilbash*, &c. 3 vols. Philadelphia—E. L. CAREY & HART.—This is a change of scene, though scarcely of incident, for this writer; for it is still of wild mountain regions and lawless tribes that he writes—though the circumstances of climate and country, where the scene is laid, divest these volumes of the gorgeous accompaniments of his Eastern stories. The Highlands of Scotland, their scenery, manners and wild denizens including man, are delineated with the author's practised hand in these pages—which, from a hasty glance, at them, will not fail, we apprehend, to interest.

DOMESTIC HAPPINESS PORTRAYED: OR, A REPOSITORY FOR THOSE WHO ARE AND THOSE WHO ARE NOT MARRIED; 1 vol. New York, CHARLES HUSBELL.—This is mainly a republication of an old book, with however some prize Essays written for the present volume, and several other original papers, now published for the first time.

It is a compilation from writers of acknowledged merit, in honor of the married state, and laying down rules and inculcating precepts for better assuring the happiness of that state. It is consequently a book that interests, as it is adapted to, both those who are, and those who hope to be, married.

MECHANICS' MAGAZINE AND REGISTER OF INVENTIONS, &c., for May. By D. K. MINOR, N. Y. THE APPRENTICES' COMPANION; No. 2. By D. K. MINOR.

Both these publications address themselves so immediately to the interests as well as the intelligence of the mechanics, that we have only to repeat the high estimate we put both upon the design and the execution of these periodicals.

STANDARD WORKS OF THE SOCIETY FOR THE DIFFUSION OF CHRISTIAN KNOWLEDGE; Nos. I., II., III., IV., V., VI., and VII. Price 6 1-4 cents, New York, ISRAEL POST, agent, 80 BOWERY.—On the appearance of the first number of this cheap and most laudable publication, we expressed our hearty concurrence in its object, which is—mainly—to put into the hands, or at least within the reach, of all, the best and most approved treatises in vindication of the authority and truth of the Bible; and to do so in the same cheap and accessible form, in which so much infidel poison is circulated; the bane and antidote being thus before the public, they are free to choose, and the peril of a wrong choice, none can absolve them from. The first six numbers comprise Bishop Watson's Apology for the Bible, in letters originally addressed to Thomas Paine, in refutation of the second part of his *Age of Reason*, and the Apology for Christianity, addressed in like manner to the historian Gibbon, in reply to the

famous chapters xv. and xvi. of his *Decline and Fall*, purporting to be "a candid but rational inquiry into the progress and establishment of Christianity." The general assent yielded to the arguments and eloquence of these two "Apologies" abundantly justify their selection, to head the list of "Standard Works."

No. VII. is devoted to a more modern, but not less admirable tract—that of Archbishop Whately, entitled "Historic Doubts relative to Napoleon Bonaparte." The happy idea of taking the arguments of philosophical doubters, such as Hume, and using them to disprove an acknowledged existence—like that of Napoleon—in order to show the fallacy of such arguments when arrayed against the Bible—is most happily carried out in this publication: and he who will read it, and then compare it, with Hume's essays, will admit we apprehend, that the fact of such a personage as Napoleon having lived and acted in our day, is to say the least, as questionable, as the authenticity of the Bible or of the miracles it records.

BACHELER'S RELIGIOUS MAGAZINE, &c. Vol. I. No. II. By ORIGEN BACHELER, New York.—After a considerable interval, we are glad to find this second No. published; since we are well assured, that, the more light is thrown upon the subject of the idolatries and false religions of other days, and other lands, the firmer will be the conviction of the truth of the Christian dispensation, which enlightens and improves, our own.

SUMMARY.

We relate the following circumstance without fear of being accused of merely telling a *snake story*, knowing the facts from the most unquestionable authority. A few days since, but a few miles distance in Jersey, a large hawk, seemingly in great hunger, was discovered hovering over the barn yard of a cottage, eagerly watching his opportunity to pounce upon the poultry below. After repeating his visits for a few days, he was fired at, but being missed, did not afterwards make his appearance. In the course of a few days the gentleman who made the shot was walking over the neighboring grounds, when he discovered a dead hawk, apparently but a short time deprived of life. Upon examination, the cause of the hawk's death was discovered to have been the swallowing of a living rattlesnake, which had eaten out of the stomach of the bird, and nearly through the skin near the craw. The snake was about eleven inches long. The hawk was no doubt the same that eagerly watched the poultry, but fearing to return, and becoming famished for want of food, was obliged to eat his snakeship. The stomach of the hawk contained no food—it was stuffed, and now graces the private collection of a naturalist.—[Gazette.]

[From the Journal of Commerce.]

FROM BERMUDA.—By the schr. Brilliant we have Bermuda papers to April 28th, and a letter of the 29th.

The Colonial Legislature met on the 27th. The Acting Governor, in his speech at the opening of the session, said, "It affords me much gratification to be able to state that the great measure of granting unqualified emancipation to the slaves, which engaged the attention of the Legislature during its last session, has been followed by no interruption of the public tranquillity. Since the abolition of slavery, there has been no perceptible increase either of crime or vagrancy in this community, and I confidently hope that the liberal course so unanimously adopted by the Legislature of Bermuda, will tend to the general prosperity of the Colony." Correspondence of the Journal of Commerce.

Hamilton, Bermuda, April 29, 1835.

The ship Henry from Liverpool bound to Mobile, came into St. George's yesterday, having in tow the barque America, from Matanzas bound to Hamburg, laden with coffee and sugar, which vessel she fell in with in a sinking state. Report says that the master of the America promised the master of the Henry one half the value of the vessel and cargo—if he should succeed in getting her in to port. The agents have however put them into the Admiralty Court. I cannot at present give further particulars, as my messenger of to-day has not yet reached her.

Perhaps at no time from the earliest history of the United States, has every branch of industry been so prosperous as at this moment. The merchant, mechanic, and farmer, is each enjoying unusual prosperity. Real estate is rapidly advancing, not only in our large cities, but in all our towns and villages, and the ability to produce, and consume, all the necessities of life, is increasing at a rapid rate. What can be the meaning of all this? We think we can name one of the causes. The wonderful change in respect to the use of intoxicating drinks throughout the whole Union, is operating on its prosperity, to an almost incalculable extent.—The farmer has discovered that stimulating drinks are not necessary to the culture of his farm; he has discovered that to produce grain for the brewery, or distillery, is a dead loss to the community. Just in proportion as the use of intoxicating drinks diminishes, the riches of the country increase.—If, therefore, our men of wealth desire to have their property confirmed and raised in value,—if they wish to see their warehouses filled with the products of the farmer, and their country unchecked in its prosperity,—let them use every proper means to disseminate, through the press or otherwise, the great principles of Temperance, so that every family in the Union may hear and know its health and wealth-giving power. From calculations, which we believe entitled to full credit, it is found, that on an average, each of the 2,000,000 of families, in the country, have been consuming to the extent of \$50 per year, in strong drink; and it has been supposed that the consumption in this way of one dollar, occasions in some way, the loss of another, so that the yearly loss to the nation, by its consumption of intoxicating drinks, has amounted to about 200,000,000—a mighty sum indeed, a sum totally lost to the country, and expended without receiving any equivalent benefit.

At this time, (such is the intelligence of the mass of the people) nothing is wanting to induce them to adopt the principles of the Temperance reform, and save all this enormous, and useless, expenditure of time, and money, and of suffering not to be estimated, but facts and sound argument—such facts and arguments as may be commanded and spread far and wide, by means of the Press—if that Press is only supported by the wealthy and the influential. It is believed that every dollar thus far expended to scatter information on the subject of temperance, has saved a thousand to the nation, and will continue to save at the same rate for years to come.—[Communicated.]

**FLOUR.**—The price of this article, which had risen recently, is said now to be pausing. Some accounts from Rochester to-day, however, which we have seen, quote wheat there as from 9s. to 9s. 6d. per bushel, which does not look like a fall in the price of flour. The supply, it is said, will not by any means equal that of last year.

The remains of Gen. Leavenworth are on board the ship Yazoo, under charge of Major Belknap, and are to be taken to Delhi, N. Y., for interment.

[From the N. Y. Daily Advertiser.]

The New York Sunday School Union held their nineteenth anniversary on Monday. In the forenoon the Schools assembled at their various churches and in the afternoon assembled in the Park, where Hymns of Praise were offered up. They were addressed by the Rev. Mr. Cox, of London, and the exercises were closed by a Prayer from the Rev. Dr. Milnor. In the evening the Society held their meeting in the Chatham street Chapel.

E. Lord, Esq., was called on to preside. The Rev. Amos Sutton, opened the meeting with prayer. Mr. Horace Holden then read the report of the last year's proceedings, by which it appeared that the number of scholars had considerably increased. After the report was read, the meeting was addressed by the Rev. E. W. Baldwin, the Rev. R. W. Dickenson, the Rev. T. M. Krebs, Mr. T. A. Packard, Secretary of the American

School Union, and the Rev. Dr. Milnor. The Rev. Dr. Matthews, then closed the meeting with prayer and it separated about 10 o'clock.

For the annexed abstract of the annual Report we are indebted to the Editors of the Observer:

The Sabbath school system was introduced into New York in 1816. The number of schools under the care of this society is now 67, conducted by 965 male and 1,030 female teachers; total, 1,995, of whom 1,633 are professors of religion, 626 have been pupils, and 101 have professed religion since the last report.

The number of pupils is 13,303, viz.	
4,401 white boys.	5,542 white girls.
382 col'd boys.	478 col'd girls.
131 col'd adults.	273 col'd adults.

5,915 7,393  
Of the pupils, 142 have made a profession of religion since the last report. Thirty teachers and eight pupils have commenced preparations for the ministry during the year. Sixteen teachers and 88 scholars have died during the year. Sixty-three libraries contain 21,874 volumes.

The 104 teachers and 142 pupils who have united with the church, added to the former aggregate of 3,483, make 3,799. The 30 teachers and 8 pupils who are preparing for the ministry, added to the last aggregate of 281, make 319.

Many of the schools now have infant classes connected with them, and much good is anticipated from this measure. In 23 of the schools there are 1,456 infant scholars.

It is supposed that this city contains from 40,000 to 50,000 children between the ages of 4 and 16. The Board believe that the number of pupils in the Sunday schools of the Methodist, Episcopalian and Reformed Dutch churches not connected with their Union, is about equal to that of the churches attached to the Union, so that the whole number of Sunday scholars in this city is about 25,000.

**LAND SALES.**—Notice is given, by proclamation published in the Government papers, that public sales of land will take place at the places and times following, viz:

At the land office at Detroit, in the Territory of Michigan, commencing on Monday, the 10th day of August next.

At the land office at Mineral Point, in the Wisconsin district, in the Territory of Michigan, commencing on Monday, the 7th day of September next.

In the State of Indiana, at the land office at Laporte, on Monday, the 7th day of September next.

At the same place, in continuation, commencing on Monday, the 21st day of September next.

At the land office at Fort Wayne, on Monday, the 12th day of October next.

At the land office at Danville, in the State of Illinois, commencing on Monday, the 21st day of September next.

**THE MICHIGAN WAR.**—The National Intelligencer of yesterday publishes the annexed letter from Columbus, Ohio, affording the most recent intelligence of the state of this—war.

COLUMBUS, May 7, 1835.

Gentlemen—The Governor and his suit, Commissioners, Chain-carriers, &c. arrived in this city last evening, being unable to finish the running of the line, in consequence, as they state, of the superior force of Michigan. The Governor intends to convene the Legislature about the first Monday in June, for the purpose of asking an appropriation to defray the necessary expenses of such a force as he may deem necessary to accomplish the intention of the Legislature, in the act of last session, providing for the resurvey of the boundary line, and the extending of jurisdiction over the territory in dispute. I think that the appropriation will be made, though it will meet with considerable opposition. Yours, &c.

By the Buffalo Commercial Advertiser of the 9th inst., we find that Messrs. Rush and Howard, "the Commissioners," as they are called of the President, to the State of Ohio and the Territory of Michigan, had arrived in that city.

Green peas and fine Green Turtle were on the dinner tables at Barnum's City Hotel on Saturday last. At Page's Hotel on Saturday, Sheephead, Lobsters and green Peas, were served up.

#### HEAD QUARTERS OF THE ARMY.

Adjutant General's Office,  
Washington, 1st May, 1835.

[Order No. 24.]

Promotions and Appointments in the Army since the first of January, 1835.

#### 1.—PROMOTIONS.

##### Corps of Engineers.

Second Lieutenant Alexander H. Bowman, to be First Lieutenant, 21st January, 1835, vice Tuttle, deceased.

Brevet Second Lieutenant Frederick A. Smith, to be Second Lieutenant, 21st January, 1835, vice Bowman, promoted—(brevet 1st July, 1833.)

##### First Regiment of Artillery.

Brevet Captain Justin Dimick, First Lieutenant, to be Captain, 6th April, 1835, vice Churchill, promoted.

Second Lieutenant Edmund French, to be First Lieutenant, 25th February, 1835, vice Ramsay, appointed Captain of Ordnance.

Second Lieutenant William Palmer, to be First Lieutenant, 6th April, 1835, vice Dimick, promoted.

Brevet Second Lieutenant Thomas A. Morris, to be second Lieutenant, 25th February, 1835, vice French, promoted—(brevet 1st July, 1834.)

Brevet Second Lieutenant R. T. P. Allen, to be Second Lieutenant, 6th April, 1835, vice Palmer, promoted—(brevet 1st July, 1834.)

##### Second Regiment of Artillery.

Second Lieutenant John C. Casey, to be First Lieutenant, 30th April, 1835, vice Mercer, resigned.

##### Third Regiment of Artillery.

Brevet Major Sylvester Churchill, Captain of the 1st Regiment of Artillery, to be Major, 6th April, 1834, vice Brooks, promoted.

##### Fourth Regiment of Artillery.

Brevet Lieutenant Colonel Alexander S. Brooks, Major of the 3d Regiment of Artillery, to be Lieutenant Colonel, 6th April, 1835, vice Jones resigned.

Brevet Captain Harvey Brown, First Lieut. to be Captain, 10th April, 1835, vice Schmuck, deceased.

Second Lieutenant William A. Thornton, to be First Lieutenant, 31st January, 1835, vice Wilson, resigned.

Second Lieutenant Thomas J. Cram, to be First Lieutenant, 10th April, 1835, vice Brown, promoted.

Brevet Second Lieutenant John H. Miller, to be Second Lieutenant, 31st January, 1835, vice Thornton, promoted—(brevet 1st July, 1833.)

Brevet Second Lieutenant James L. Davis, to be Second Lieutenant, 10th April, 1835, vice Cram, promoted—(brevet 1st July, 1833.)

##### Second Regiment of Infantry.

Brevet Captain John Bradley, First Lieutenant, to be Captain, 22d April, 1835, vice Clarke, promoted.

Second Lieutenant Amos B. Eaton, to be First Lieutenant, 22d April, 1835, vice Bradley, promoted.

Brevet Second Lieutenant James T. V. Bonford, to be Second Lieutenant, 22d April, 1835, vice Eaton, promoted—(brevet 1st July, 1832.)

##### Sixth Regiment of Infantry.

Brevet Major Newman S. Clarke, Captain of the Second Infantry, to be Major, 22d April, 1835.

Second Lieutenant Joseph D. Searight, to be 1st Lieutenant, 30th April, 1835. Vice Richardson, resigned.

Brevet Second Lieutenant John Conrad, to be Second Lieutenant, 30th April, 1835, vice Searight, promoted—(brevet 1st July, 1831.)

##### Seventh Regiment of Infantry.

Second Lieutenant Theophilus H. Holmes, to be First Lieutenant, 26th March, 1835, vice Newell, deceased.

Brevet Second Lieutenant Henry McKavett, to be Second Lieutenant, 26th March, 1835, vice Holmes, promoted—(brevet 1st July, 1834.)

#### 2.—APPOINTMENTS.

##### Staff.

Charles Mapes, to be Paymaster, 7th January, 1835.

Pe'er Muhlenburg, to be Paymaster, 9d February, 1835.

Samuel R. Moore, to be Assistant Surgeon, 14th March, 1835.

Alexander F. Suter, to be Assistant Surgeon, 27th March, 1835.

## Ordnance Department.

First Lieutenant George D. Ramsay, of the 1st Regiment of Artillery, to be Captain, 27th February, 1835, vice Hills, deceased.

## 3—CASUALTIES.

## Resignations.

## Lieutenant Colonel.

Roger Jones, 4th Artillery, 6th April, 1835.

## First Lieutenants.

Hugh W. Mercer, 2nd Artillery, 30th of April, 1835.

Horace A. Wilson, 4th Artillery, 31st January, 1835.

Asa Richardson, 6th Infantry, 30th April, 1835.

## Second Lieutenant.

Theophilus F. J. Wilkinson, 3d Artillery, 28th February, 1835.

## Brevet Second Lieutenant.

Goode Bryan, 5th Infantry, 30th April, 1835.

## Staff.

Benjamin R. Hogan Assistant Surgeon, 30th April, 1835.

## Deaths.

Captain John Hills, Ordnance, 25th February, 1835.

Captain Jacob Schmuck, 4th Artillery, 10th April, 1835.

First Lieutenant Stephen Tuttle, Corps of Engineers, 21st January, 1835.

First Lieutenant John E. Newell, 7th Infantry, 26th March, 1835.

Second Lieutenant Walter S. Chandler, 2d Artillery, 25th January, 1835.

## Staff.

Ephraim M. Blane, Assistant Surgeon, 13th March, 1835.

Samuel W. Hales, Assistant Surgeon, 30th January, 1835.

2.—The officers promoted and appointed, will report accordingly, and join their proper stations and companies without delay: those on detached service, or acting under special orders and instructions, will report by letter, to their respective Colonels.

By order of ALEXANDER MACOMB,

Major General, Commanding in Chief;

ROGER JONES, Adjutant General.

"The frigate Constitution made the passage to Havre in twenty-four days. The Commodore was requested to use all possible speed, and it seems that he did. The old ship never crossed the Atlantic so rapidly before."—[Going the rounds.]

The Constitution frigate is said to be the fastest sailing vessel belonging to the United States, yet she only kept pace on her passage to Havre with the packet ship *Havre*, both having left this port on the 16th March, and both arrived at Havre on the same day, (9th of April,) the latter a few hours ahead. But the packet ship *Britannia*, which also sailed in company with the Constitution, arrived at Liverpool on the 8th, and beat the later one day in her passage. We notice this circumstance because it is generally supposed that no vessels can compete in sailing with ships of war. We question whether the vessels of war of any nation can "go ahead" of the New York merchant packets.—[Advocate and Journal.]

THE URSLINES.—We are glad to find by the annexed article in the Boston Commercial, that the rumor of recent insults to the Ursulines at Roxbury, is unfounded.

The reported attempt to disturb the Convent at Roxbury on the night of the 6th, it appears from certificates which have been shown us, is without foundation. It arose from a number of young men belonging to Roxbury, who had been to Brookline on that evening to serenade some friends, stopping a short time in front of the Convent, where they played a few tunes and sang a song.—One of the certificates shown us, is from the Lady Superior, in which she says, she has "occasion to believe no insult was intended, but on the contrary the party who stopped before the Convent were actuated by kind and complimentary feelings, as has since been ascertained, although the young ladies experienced at first very great alarm."

The Hudson paper of Monday, in reference to the persons injured by the explosion on board the steam boat *Advocate*, says:

"We are informed that J. L. Brook, Esq. is still in a dangerous situation, and has not been removed from Coeymans, that Col Butler is fast recovering, and that two more of the children of Mr. Smith have died."

## FOREIGN INTELLIGENCE.

LATER FROM FRANCE.—By the ship *Citizen*, a transient vessel from Havre, there are accounts two days later than those before received.

MADRID, April 2.—The Colombian Generals Soublet and O'Leary arrived here yesterday, with powers to treat for an acknowledgment of the independence of the Republic, and have to-day had an audience of the President of the Council. The Government has received very favorable reports from the Commandant of the Provinces, as to the progress of the recruitment for the army. Hitherto, all the men called into the service have entered with the utmost alacrity, displaying great zeal and ardor. The Ordinance interdicting the soldiery from singing patriotic songs and uttering cries, has produced serious disturbances at Malaga. The Ordinance was published at the moment when the funeral of an Urban Militiaman was taking place, attended by a long train of his friends. The band which preceded the procession, having begun to play Riego's March, the Governor sent an Adjutant to order it to cease, but as this injunction was disobeyed, the armed force interfered, and a contest ensued, and the Governor became so much alarmed, that he left the town. Malaga being thus left without any authority over it, a provisional Junta, was formed, and the people demanded the re-establishment of the Constitution of 1812. The new Junta, however was fortunately composed of moderate men, who appointed a new Governor devoted to the Queen. Thanks to this energetic measure, the Carlists, who had begun to post up their proclamations were reduced to subjection and order was restored. General Lopez, on the 17th ult. received a challenge from Don Louis O'Donnell, the Commandant of the cavalry of Don Carlos to meet him with an equal number of cavaliers, armed only with their swords. Gen. Lopez replied that he not only accepted the challenge but would come to the place of rendezvous, whenever it might be appointed, with 100 men less than his adversary. A curious publication, showing the number of victims that have been sacrificed by the inquisition, has just appeared, and according to which 105,286 fell under Torquemada, 51,137 under Cisneros, 34,952 under Diego Perez.

Those who suffered under the Inquisitors who preceded these three monsters, amounted to 3,410,215. It is reckoned that 31,912 have been burnt alive, 15,659 have suffered the punishment of the statute, and 291,450 that of the penitentiaries.—500,000 families have been destroyed by the Inquisition, and it has cost Spain two millions of her children.

PARIS, April 11.

Reports have been several days in circulation of Algiers being exposed to great danger from the Arabs, and yesterday it was rumored that it had fallen into their hands. The Ministerial Evening Journal, after noticing that the reports current are more than exaggerated, gives the following:—"The Government has received news from Count d'Erlon to March 29th. The tribes of the West having formed some tumultuous assemblies beyond the Chiffa, Gen. Rapatel marched on the evening of the 27th from the camp of Bouffarik, at the head of the 10th Light, two companies of Zouaves, two squadrons of the 1st regiment of African Chasseurs, a squadron of Spahis, and some pieces of Artillery, to disperse these crowds.—He was the next day at Bouffarik, and wrote as follows to Count d'Erlon: 'I was this morning on the Chiffa; the Chasseurs and the Spahis crossed it at day break, and charged the crowd. The enemy did not keep his ground an instant, but had several killed and wounded in this charge, which took us more than two leagues beyond the river. In returning, the enemy followed us a league on this side of the Chiffa, renewing his flight as soon as we charged him anew. He fell into some ambuscades that I had laid for him. He had 60 men killed or wounded, and we had not a single man killed.' Count d'Erlon had recommended to Gen. Rapatel to make only one *coup de main* upon these crowds of the West. The troops which occupy the camp d'Erlon are under cover, and in safety, and those with which it had been judged expedient to reinforce them, have received orders to return to their cantonments."

In the following statements derived from a London paper, we find truly honorable instances of the proper use of patronage and wealth.

The following facts ought to be known: they do equal honor to Sir R. Peel's discernment and liberality:

On Monday last Mrs. Somerville received an autograph letter from Sir R. Peel, informing her in the most delicate style of compliment that the knowledge of her acquirements in science had made it his duty to submit to His Majesty the propriety of granting to her a pension on the civil list of 900*l.* a year. Mrs. Somerville's letter of thanks was accompanied by a copy of her book. The day following (Thursday last) she received a handsome acknowledgment for the book, with an expression of regret that it had lost the charm of novelty, as he had already read it in the first edition.

The Rev. Mr. Milman has also received an autograph letter from Sir R. Peel, offering this shamefully persecuted author of the admirable *History of the Jews* the living of St. Margaret's, Westminster.

Mrs. Hemans, who has employed her talents entirely for the support of a large family, having been long since deserted by her husband, was lately, within ten days, most dangerously ill. In this state, in bed, with a pencil, she wrote some beautiful verses, which were sent to her friend, the accomplished Mrs. Lawrence, of Liverpool, who sent them to a nobleman in London, who was so struck with them and the unhappy situation of their author, that he took them to Sir R. Peel, who instantly desired the nobleman to cause Mrs. Hemans' eldest son, about 18 (who has been educated gratis by Dr. Butler, of Shrewsbury,) to come to London to receive an appointment in a public office, whilst Sir R. Peel himself wrote a letter of condolence to the mother, enclosing a bank note of 100*l.* for his outfit.

HISTORY OF IRELAND by Thomas Moore.—Of the first volume, the only one that has yet appeared of this publication, which is part of the Cabinet Cyclopaedia, the London Literary Gazette, thus speaks:

The learned Rudbeck, see his *Atlantica* in four volumes folio, ascribes the building of an ancient temple in Sweden to one of the sons of Noah; and, after numerous pros and cons, cautiously expresses his suspicion that "it was probably the youngest son!" In the spirit of "the learned Rudbeck," Mr. Moore has begun his history sufficiently early, though he has only thought it necessary to commence regularly with the Celtic origin of the Irish, a thousand years before the Christian era. In the after discussions, however, he makes some amends for this antiquarian and national moderation, by a few references to the deluge and antecedent times; but nothing like the Welsh pedigrees, where Adam stands about the middle of the tree; we mean the genealogical Tree, and not the Tree of Knowledge.

Under these circumstances, the first volume, which marks the accession of so popular a contributor to this monthly series, does not offer us much on which to exercise our critical propensities. Irish antiquities have often amazed and puzzled us; and having dealt with St. Patrick, Adamnan, Keatinge, Vallancey, Ledwick, Milner, O'Halloran, O'Connor, Betham, Lanigan, O'Brien, &c. &c. &c., we are the less inclined to meddle with their dicta, as likened into a new and condensed form by their distinguished countryman. Suffice it to state, that the results of Mr. Moore's reading and investigation are principally that the Irish are of Celtic origin, and very early connected with the east, probably with Persia;—that their intercourse with the Phenicians was also anterior and superior to that of Britain, and that the "Sacred Isle" was peculiarly famed and glorified;—that the round towers were fire temples; and that very considerable civilization prevailed before authentic dates can be attributed to historical facts;—that letters and learning were cultivated by the first Druids; and that they were different from the Milesian or Scotic, as they were from the Belgic or Gaulic races;—that they were also different from the Welsh, who are of Pictish and Cimbric origin;—that Argyleshire was conquered by the Irish and the kings of Scotland, descended from them;—that the pretensions of Scottish writers are groundless forgeries, and Osian a bit of a humbug;—that Christianity was introduced by readier means and in a purer system by St. Patrick, than into any other land; and that Ireland has been grievously oppressed and betrayed, almost ever since it sprang from the sea. Accounts of the Saints, and a good deal about the Paschal controversy, complete the volume.

[From the Gazette des Tribunaux.]  
**The Mysterious Deposit.**  
 COUR ROYALE DE TOULOUSE.

No doubt our readers will recollect the narrative we published, a short time back, of the suicide of M. Daure, the former Secretary of M. de Talleyrand. The singular circumstances attendant upon this event must have made a deep impression upon every mind.

Some hours before the fatal moment, M. Daure sent to the Abbé Marcelin, at Montauban, in whom he had long reposed the most perfect confidence, sundry papers and a trunk which was locked up, with the injunction either that it was not to be opened before the 1st March, 1835, or that the same should be delivered up to a person who would come from Paris to claim them. M. Daure's mother, who suspected that the trunk contained a considerable sum of money, demanded to have detailed particulars of its contents. The Abbé Marcelin declined to allow the secrecy of the deposit intrusted to his friendship and discretion to be violated. In consequence of this refusal, and of the persistence of Madame Daure, the Royal Court of Toulouse was called upon to decide the disputed point.

Before the discussion of the legal question by the advocates, the Abbé Marcelin conceived it to be his duty to state the facts which had forced him to appear before the Court.

"On the 19th of November last," said he, "I returned home from the country at about ten at night. I had already retired to rest, when a message was brought to me requiring my immediate attendance at a house which was named to me, for a very pressing matter. I repaired thither. 'Here is a trunk addressed to you,' said a person to me; it has just arrived; it is sent by M. Daure, who announces to us that he is about to commit suicide!"

"The person who thus addressed me did not appear to believe that this violent resolution would be adhered to. For my part I thought differently. I knew that Mr. Daure was not a man to say, 'I am going to kill myself!'—without doing so. I rapidly gathered together all the things which were addressed to me, and I prepared to set out for Penne. At midnight I was on my way; and I buoyed myself up with the hope that Daure was still living, and that I might, perhaps, save him. He was dead! In about three quarters of an hour after he had sent off the messenger with the things confided to me, he blew out his brains! On my return to Montauban, I took cognizance of the papers which had been sent to me; I had merely cast my eye over them before. Among these writings there were several which were to be read by me, and afterwards burnt. Others were to be sent to their addresses: among the latter was M. Daure's will in favor of his mother; this document was unsealed, and in his mother's absence I delivered it to his sister, Madame Vignais, in presence of an old woman, who also appeared to me to belong to the house. Among the small number of papers which I was to preserve was this letter, which I am bound to read to you, gentlemen, although it is too flattering towards myself:—it is the title by which I hold the deposit, (here the Abbé read the letter.) You must have remarked, gentlemen, the precision with which every sentence of this letter is written. I ask of you what is the signification of the following precise and clear lines, so full of calm, that one would almost be inclined to hesitate at believing they were written in the presence of death? 'No one—absolutely no one upon earth is to see it—you have no account to render to any living soul; your conscience is the only tribunal to which you have to look in this respect! \* \* \*'"

"Do you believe, gentlemen, that the man who addressed me thus could, a few hours afterwards, appoint any person 'upon earth' to look into the trunk to oblige me to 'render an account to any living soul'—to submit to the jurisdiction of any other tribunal than that of my conscience? I have not been able, gentlemen, to afford myself that melancholy, but consoling conviction, that my friend died under the influence of those hallucinations which carry off at one and the same time both the resolution and the will, and the conscience. Unhappily I had seen too clearly the foundation for this suicide to be able to attribute it to what we call madness. I confess, however, my opinion in this respect, and look upon Daure, not as a guilty suicide, but as a poor madman who was to be pitied, if the authority given to his mother (an authority which she declares she received after his communication to me) was such as she pretended: it would then remain

to have this act of madness explained; in the midst of a series of acts which might appear extraordinary to the mass of mankind, but of which I—I know the desperate logic."

The Abbé Marcelin maintained that Madame Daure had exaggerated the financial position of her son.

"Daure," he said, "was so well known to possess nothing of his own, that all through his life the most infamous suspicions hung over him; his apparent fortune was surrounded by so much mystery that persons thought proper to spread the report that Daure was a spy for high personages. This is an atrocious calumny, which I repulse with all the energy I am capable of, and all the indignation of an enlightened conscience! Daure had so little money, Gentlemen, that a short time before his return to the south he claimed in the most pressing manner 1500 francs, which he had left in the hands of a friend before his departure."

The Abbé then explained the nature of his connection with Daure. He had never written direct to the Abbé from Paris: he spoke a good deal of him to others. Once only a letter was sent him, inclosed to one of his friends. Therein he wrote—

"I could wish to tell you several things, but cannot at present. However, you know how to comprehend so much and so well. I have sold the few things I had here, and am going in a few days to Germany. Perhaps I shall soon acquaint you that I have entered a convent of Trappists, which I once visited in the midst of the forests of Bohemia."

"This was written," said the Abbé, "in the beginning of September last, when he already contemplated making way with himself."

"I could wish, Gentlemen, that it were as clear to your minds as it is to mine, that in acting in regard to me as he did,—Daure did not look upon me as a man upon whom he was desirous to confer a favor, but of one whom he considered worthy of being made the depository of a secret,—as a man who knew all the most secret episodes of his life, who had divined his virtues as well as his defects, and who was able, as a priest, to complete the former, and obviate the fatal consequences of the latter."

"I have not been able to call exactly to mind the period when Daure quitted Montauban for the last time. I think it was in the beginning of last summer. I do not know what he was doing in Paris. All I know (for his friends have since written to me to that effect) is that it was visible to every one what a strange evolution had taken place in his character, and that disastrous projects disturbed his mind. An understanding was come to to endeavor to divert him from those dreadful pre-occupations. The Duchess de Dino conferred on the subject with M. Guizot, who had a particular esteem for Daure. The Minister wrote to invite him to call upon him the next day, at eleven o'clock. This was to inform him of his nomination to an employment which it was believed was perfectly suitable to his taste. Daure was all his life susceptible to a degree, and he became even more so as his death approached. He wrote to the minister, in answer, 'If the minister wishes to speak to me, I live in such a street—such a number.' At length he was enabled to leave Paris, and, as he said, to tear himself from his odious pursuits. I went to Germany, returned again to Paris, and quitted it again for the south. His death was inevitable; he could no longer bear up against the imperishable sorrows of which he had spoken so much to me. Every line he wrote proved this.—Thus in the diligence, seeing that a husband took offence at the attentions, full of noble delicacy, which he paid to his wife, he said to himself, 'How singular—this is the first time that a man has been jealous of death!' Daure left the diligence at a distance of two hours' journey from Montauban, and thence, during the night, in a cart, and lying upon his trunk, he took the direction of the wildest spot in the Department, Bruniquet. There his presence, and the mystery with which he constantly had the mania to surround himself, excited the attention of the gossips. As he says in one of his letters, he retreated before a set of old women, and letting his horse wander whither he pleased, plunged into the profound ravine of the Aveyron, and arrived at Penne. In his description of this wild spot he wrote, 'Here is a place which is fit to make one in love with death.' He established himself then at Penne. In the house of a respectable man, by whose delicate attentions and hospitality he was arrested for some time on the brink

of the tomb. I only knew of his arrival at Penne eight or ten days before his death. I knew nothing of his fatal intentions, although the letter he wrote just before his death proves that they were long before matured. This, Gentlemen, is all that my conscience, to which an important secret is intrusted, permits my voice to declare to you. Do not demand proofs or explanations from me, for at the slightest question I shall cease to speak, and nothing shall force me to break silence. I am ignorant as to what the law will dictate to you relative to the cause of this suicide. I have been faithful to the last to friendship and to the dead, and I have taken for the guide of my conduct these words, the last which Daure has left us—'Remember that the dead have no other avengers upon earth than the conscience of the living.'"

The Court, by consent of all parties, ordered that seals should be affixed to the trunk; that they should not be removed before the first March; that this operation should not take place otherwise than in the presence of M. Comac, Judge of Montauban, who should deliver to the Abbé Marcelin such papers as were not titles to property, as well as the letters, the said judge not to be allowed to read the addresses of those letters.

#### The Marquise De Crequy.

The fifth, and, we fear, the all but concluding volume of the amusing memoirs, published under the above name, has just appeared; and, if less entertaining than its predecessors, as treating of times more familiar to the general reader, contains innumerable curious anecdotes of a light nature, a few of which we propose translating for the benefit of our readers.

**Fashion.**—"I have seen the rise and fall of all sorts of ridiculous fashions," writes the old Marchioness. "During the time of the Regency, it was the custom to wear upon one's temples any-dye plaisters, as a remedy against the vapors; and, by way of rendering them ornamental, they were adorned with small diamonds, points of cut steel, or garnets; so that they had the appearance of being nailed to the temple by an infinite number of small nails. Gold hair powder, extremely unbecoming to both brown and fair, was also in vogue; and high-heeled shoes, whose dimensions rendered it necessary to walk on the extreme points of the toes. But all these follies were nothing to the style prevalent among our fashionables immediately before the revolution. The men were shut up in tight coats, called, after the English, a frock, sloped off, so as to make an indecent exhibition of the hips, and ending in a swallow's tail. These frocks were chiefly worn of scarlet cloth, with buttons the size of a crown piece, composed of a circle of gold surrounding a watchglass, under which was seen a collection of rarities,—such as sprigs of moss or sea-weed, curious insects, diamond beetles, and cantharides. With a red coat, it was indispensable to wear a muslin waistcoat, black silk breeches, and silk stockings of blue, shot with white. The hair was dressed *à la débâcle*, with a tiny queue, and seven or eight ounces of powder on the collar and back of the coat. Two long watch-chains, each having a large bunch of gold bells, hollow acorns, or other trinkets capable of making a tinkling noise, which were called breloques, completed the costume; with a little cane in the hand, such as are used by footmen for beating coats. These were said by the young courtiers to be "excellent weapons for fighting cats!"

"The head dresses of the ladies, meanwhile, had attained a most absurd elevation. Carriage cushions were necessarily abolished; and, in their stead, a slight wadding was used, about the thickness of a Montpellier scent bag. What the hair-dresser had the art of sticking on the top of a female head, under the name of Puffs, Touquets en Lubie, and Valgalas, is scarcely credible! Leonard, the hair-dresser (whom Monsieur used to call the Marquis de Leonard, to distinguish him from his brother, the Chevalier, who only consented to cut hair), boasted that he would dress the Duchesse de Luges, who, relying on his address, seldom looked in the glass, with one of her own chemises; and Madame Thibault, the Queen's bedchamber woman, obtained her Majesty's sanction to the exploit. The Duchess accordingly arrived at Court (luckily there was a general mourning) with one of her own cambric shifts twisted into her hair. This adventure brought similar follies into fashion, and, a few days afterwards, Madame de Luval appeared at Court with a damask napkin for her head-dress, which every one found in admirable taste. In the

year 1785, the *Marche de Matignon* chose to be a coffee a la Jardiniere for Court, by Leonard; with a checked napkin of brown and red calico, in which appeared a head of green brocoli, an artichoke, a pretty little carrot, and some radishes. Madame Charles de Lameth exclaimed "Lord! how delightful!—nothing but vegetables!—I don't upon vegetables!—they seem so much more natural than flowers."

"By way of being 'natural,' too, my relation, the Countess de Clermont Tonnerre, used always to stir the salad with her fingers; and, after supper, when she amused herself with patting or boxing the ears of her 'dear Stanislas,' the Count used to exclaim—'Delicious creature! Her carresses make me hungry with the scent of Tarragon vinegar and Jamaica pepper! Those pretty little hands deserve to be eaten up!'"

"A nun, it seems, would sometimes be guilty of a repartee. "When Madame de la Motte, the heroine of Maria Antoinette's diamond necklace adventure," says Madame de Créquy, "was shut up in the *Salpêtrière*, certain of the Duchesses of Chartres ladies in waiting went, on pretence of viewing the establishment, to obtain a glimpse of the criminal. At length they made a direct application for the indulgence to Sister Victoire, the Superior, who demurred, on the ground of Christian charity towards the sufferer. Madame de Blot at length insisted on the prerogative of her appointment in the Orleans family; but Sœur Victoire was inflexible. 'I did not find it written in Madame de la Motte's sentence,' she said, 'that she is condemned to receive the visit of the Duchesse de Chartres's ladies in waiting.'"

Extract from a letter of Mr. John Barlow, one of the most experienced and distinguished Engineers of London, dated on the 27th February last:

"There is one source of revenue to a Coal Gas Company, that coming into practical effect here, which promises to be of great importance, namely *cooking by gas*; I know one family who have used no other fuel for cooking for the last two years, and another who for several years have never lighted any other fire in their house, for any other purpose whatever, than gas, during the 3 or 4 hot months, and they both say it is cheaper, more convenient, cleaner, and the cooking better. Hundreds, and probably thousands of families will, in this country, be supplied with gas for cooking during the coming summer. They now roast, bake and boil by gas. The heat is always ready when wanted, and required; no up afterward either roasting till the clock. I know a few dozens, and all done up, as of the gas, in my view, is a great improvement."

#### THE FLOWER SPIRIT.

I am the spirit that dwells in the flower;  
Hence is the exquisite music that flows,  
When silence and moonlight reign over each flower  
That blooms in the glory of tropical skies.  
I woo the bird with his melody glowing  
To leap in the sunshine, and warble his strain,  
And mine in the odor, in turn, that breathing,  
The songster to paid for his music again.

There dwells no sorrow where I am abiding;  
Care is a stranger, and troubles are not;  
And the winds as they pass, when too heavily riding,  
I woo, and they tenderly glide o'er the spot.  
They gaze, and we glow in their rugged embraces,  
They drink our warm breath, rich with odor and song,  
Then hurry away to their desolate places,  
And look for us hourly, and think of us long.

Who, of the full earth, that's moving around us,  
Would ever imagine that turned in a rose,  
At the opening of spring our destiny found us,  
A prisoner until the first bud should unfold;  
Then, as the dawn of light breaks upon us,  
Our wings of silk we unfold to the air,  
And leap off in joy to the music that won us,  
And made us the tenants of flowers so fair!

#### SONG.

Give me old music—let me hear  
The strains of days gone by;  
Nor may thy voice in kindly ear,  
If to their tones my falling tear  
Should make a misty reply.  
The songs that lulled me on the breast  
To sleep away the moon,

Bring on—bring on!—I love them best;  
Thine's wachery in the notes impressed  
Of each familiar tune.

Give me old wine—its choicest store  
Drawn from the shady bin;  
Our vineyards will produce no more,  
Such rare strong juice they gave of yore,  
As sparkling lies within.  
This was my grandeur's chief delight,  
When the day's chase was o'er;  
Full high!—Full high!—its treasures bright  
Should sparkle on our board to night,  
Though we should drink no more.

Give me old friends—the tried, the true,  
Who launched their barks with me,  
And all my joys and sorrows knew,  
As chance's gales the pilgrims blew  
Across a troubled sea.  
Their memories are the same as mine;  
Their love with life shall last;  
Bring on, bring on, their smiles shall shine  
Upon our old good song and wine,  
Like sunbeams from the past.

#### WILL-BAR FOUNDRY

ON MONDAY, June 1, at 12 o'clock, at City Hall, (as previously disposed of as private sales) will be sold by auction, the above well known establishment situated one mile from Boston. The improvements consist of—

No. 1. *Boiler House*, 50 feet by 20 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. *Blacksmith's Shop*, 30 feet by 30, fitted with cranes for heavy work.

No. 3. *Locomotive House*, 54 feet by 25, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with slate, 100 feet by 40, containing two water-wheels, equal to 40 horse power; Machine Shop, fitted with lathe, &c.; Pattern Shop; Rolling Mill and Furnace, capable of rolling 4 tons of iron per day, and capable of other work; three Trip-Hammers, one of which is very large; Engine for blowing Capela Furnace, moved by water-wheel; one very large 14 horse Steam Engine, which could be dispensed with; and a variety of other machinery.

No. 5. An Iron Foundry, 80 feet by 45, with a superior air Furnace and two Capelas, Core oven, Cranes, &c. fitted for the largest work. Attached to the Foundry is a large ware-house, containing Patterns for the Castings of Hydraulic Engines, Locomotive and other Steam Engines, Land Mill Rolls, Gearing, Shafts, Gears, &c. &c. These were made of the most durable materials, under the direction of a very scientific and practical Engineer, and

containing a large stock of Cast Steel. This building, house, and crane

are long by 35, contains a Stone Foundation left for mooring post

on tide water, presents a view of business than any and iron can be carried on, to the wharf in front per ton. Some of the completed at this establishment and lift pumps by and Charleston.

is excellent, being in of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at these works. With the Patterns and Machinery now in the premises, 12 Locomotives and as many tenders, besides a great quantity of cars and wagons, could be made per annum.

For terms, apply to  
THOMAS J. ECKLEY, Treas., &c., Boston, or to  
ROBERT BALSTON, Jr., Philadelphia.  
Boston, April 21, 1838.

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

THE Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 16 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered to market.

Railroad Companies may be supplied with Spikes having counter-sunk heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are furnished with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by J. & J. Townsend, Albany, and the principal Merchants in Albany and Troy; J. I. Brewer, 223 Water-street, New-York; A. M. Jones, Philadelphia; T. Janvart, Baltimore; Degeard & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

H. BURDEN.

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 99 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.  
Also, Flange Tires turned complete.

ROBERTS, KETCHUM & GROSVENOR.

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. BRADSTOCK CORNING & CO., Albany, or to THOMASTURNER, at the Factory, Troy, N. Y.

Sept. 13-17

#### RAILWAY IRON.

20 tons of 1 inch by 1 inch, Flat Bars in lengths of 14 to 16 feet, counter sunk holes, ends cut at an angle of 45 degrees, with splitting planes and ends to suit.

200 do. of Edge Rails of 20 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 20, 22, and 26 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2 1/2, 3, 3 1/2, 4, and 4 1/2 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. BALSTON.

9 South Front street, Philadelphia.  
Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splitting Planes, in use both in this country and Great Britain, will be exhibited to those disposed to examine them.

471-mccm

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 184 Water street, corner of Maiden lane.

#### SURVEYING AND ENGINEERING INSTRUMENTS.

For more in part with Cow be a fact sent 25th

ALBANY, N. Y. JUNE 20, 1838.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

In reply to the inquiries respecting the instrument manufactured by these, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish the following information. The whole number of Levels now in possession of the department of construction of the said railroad is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that the patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Comometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane alidade, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,  
JAMES F. STABLEY, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1838.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and so much most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Georgetown, February, 1838.

For a year past I have used instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY A. CAMPBELL, Eng. Philad.

mail y. Germant. and Norrist. Railroads

**Algers as she is.**—Algers is daily assuming a more European aspect; hats are nearly as often seen as turbans, cigars have replaced the long pipes and the Moorish bazaars give way to the glazed windows of French shops. Upwards of fifty merchants have established counting-houses; and a considerable number of mechanics and tradesmen, including of course a full proportion of modistes, couturiers, and perruquiers, are thickly scattered about. Eleven grand cafés with billiard-tables, four grand hotels (which are, however, execrable,) three restaurants, one hundred eating-house, two *cabinets littéraires*, one circus, a cosmorama, &c. have already been established, and cabriolets and omnibuses were shortly to ply from the Bab hazoon to Mustafa Pasha, and from Bab el habut to the Dey's country villa. The *Musbah* is a little town in itself, containing the late Dey's palace, and several other houses and gardens. The palace has suffered much from the French soldiery; who, on first occupying it, pulled up the pavement, tore down the glazed tile coating of the rooms, and otherwise committed great injury in their eager search after treasure. The marble flooring, the arched galleries, supported by marble pillars of fantastic but graceful forms, which surrounded the open courts, the elegant fountains, which scattered coolness around, and the latticed shahsheshes, still, however, remain to pay the fatigue and trouble of the visitor's ascent. The *corps-de-garde*, with the gate, and the sycamores, banana-trees, and vines, which surround it, together with the mixture of French uniforms and Moorish costumes, formed altogether a beautiful little picture; as did also a wine-shop, shaded by a vine-covered pergola, under which were seated groups of soldiers playing at cards, drinking, flirting with some *piquant* French brunettes, or teaching "Trompette," the *chien du régiment*, a variety of tricks.—[Major Temple's Excursions in Algiers.]

**Barrack-Building at Tunis.**—On speaking to the architect and engineers, and asking them to show me their plans, they at first did not quite seem to understand what a plan was: when it was explained to them, they declared they had nothing of the sort, and that, in fact, the Moors never made any pretensions to commencing a building; but that they built by the eye a certain length of wall, and that when this had been sufficiently prolonged another was built at right angles to it, and so on. What is still more remarkable, their arches are also constructed entirely by the eye, and have no frame work to support them during the process, which is as follows:—A brick presenting its broad surface to view, is placed with its edge on the buttress, where it is to commence the spring of the arch; another is made to adhere to it by means of a very strong cement made of a gypsum peculiar to the vicinity of Tunis, which instantly hardens; on this brick is placed another in the same manner, and thus they proceed till the arch is completed. I saw a vault myself thus made in less than an hour and a half. These arches and vaults, when finished, are very graceful and correct in their proportions, and nothing can equal their strength and solidity. In building walls, an oblong frame about seven feet long, and as broad as the wall is intended to be, is placed on the foundations, and then filled with mortar and pieces of stone; in a few minutes the frame is removed, and placed in continuation of the line. This method appears to have been adopted in the construction of Carthage.—[Major Temple's Excursions in Algiers.]

**Phrenology run Mad.**—It appears that there is an *Orthophrenological* establishment at the village of Issi, near Paris, where children are received, who are incapacitated from receiving their education in a school in consequence of faulty conformation of the brain. The skulls of these unfortunate little creatures are to become the subject of physiological examination and experiment. Their encephalic mass is to be modelled, compressed, handled, and remoulded. Gall and Spurzheim merely pointed out the bumps of the different passions. They never dreamed of effacing them, and raising the bumps of virtuous propensities and genius to supply their place. They never thought of penetrating into the layers and recesses of the occiput and sinuiput, and unfolding all those connected organs and delicate net-work, where thought is formed, fixed, and developed.

This immense application of their master's system has been reserved for the bold successors of these illustrious men. They alone can have the bump of genius prominent enough to form a plan

so precious. Yet two distinguished medical men are at the head of this novel *orthophrenological* establishment. Doubtless, it will be managed by these enthusiasts with great judgment and science united. But may it not be apprehended that ignorant and covetous speculators will quickly take advantage of the credulity of the public, ever fond of the new and marvellous? And that, in these Lazarettos of human reason, wretched children will be immured whose skulls may be pronounced defective or anomalous, when submitted to the rule and compass of such empirics? They might, if left to the operations of nature, become superior characters, but will infallibly be reduced to the condition of idiots or madmen, in undergoing this process of compression and remodelling of the brain. The methodical classification of human beings into casts, according to the different degrees of their intelligence, would soon make us retrograde to the slavery of feudal times.

#### **Imprisonment for Debt as practised in England.**

Whitecross street prison is by far the largest and most extensive of the gaols in which men in this country are confined for debt. Its prisoners are more numerous, its enactments and regulations more severe, its accommodations more restricted, and its society more mixed, than those of the King's Bench, the Fleet, the Marshalsea—and we had nearly said Horsemonger lane; but we recollect that the latter is a gaol simply fit for felons, and into which it is an inhuman outrage on the first principles of justice to confine a person who has not been guilty of some marked and heinous crime. The Whitecross street prison, which has not been erected more than a quarter of a century—if so long—was built for the purpose of accommodating in one temple of sorrow, poverty and guilt, the debtor's side of Newgate, the Poultry and Giltspur street Compters, and the Ludgate prison, the three last of which were originally separate buildings in different parts of the city. The new prison was divided into wards, or compartments, named after the old gaols, and so called the Ludgate ward, the Giltspur ward, the Poultry ward, &c. Besides these, there is the Middlesex side of the prison, intended for prisoners arrested within the county, and the forty-shilling ward, for the debtors sent in by the orders of the Court of Requests, and whose embarrassments do not overtop the sum of forty shillings, until indeed they become doubled by the costs of law. We must also mention a receiving ward—the room into which debtors are ushered the first day and night of their imprisonment—a chapel, a sick ward, a strong room, a kitchen, and a sort of tap, to which the inmates have given the nomenclature of "the Scratch"—and I believe we have told of all the departments and divisions of one of the most monstrous Leviathans of tyranny and iniquity ever raised by human industry upon the curse-cemented superstructure of poverty, misfortune, persecution, dishonesty, and guilt. Within no walls, not excepting even those of the Bastille and the prisons of the Spanish Inquisition, has there ever existed so deep and heavy a load of positive unhappiness—of actual heart-breaking acute misery. Greater torture of the limb, mightier exercise of terror, more severe personal suffering, and darker dungeon-like confinement, have, we know, often hurried men to confession or to death—have broken a coward, sometimes even a brave spirit; have crushed a weak constitution, and shattered the energies of youth and hope. But these effects have in all lands taken their rise in state-tyranny—they have been visited in the fear or the suspicion of governments, or by the mad superstition of priests; or they have been the punishments of desperate treachery, or atrocious penal crimes. Never have they been the result of a widely practised and openly avowed system, founded upon laws framed by a legislature in support of a free constitution. Neither, we are prepared to prove, has the worst state or criminal prison in any other land—and we are willing to retread the path of civilization as far as one hundred years will take us back into times and practices of cruelty—disseminated so much real sorrow and real ruin too—as the English Debtors' Prison of Whitecross street, in an equal period of one, two, four, eight, or even ten years. For two instances in which they have guillotined a man's head in France, or crushed his body upon the wheel in Spain for state treason, religious heresy, or civil murder, you will find ten where they have broken his heart in England—for debt! and for one instance where the Inquisition or the Bastille, having imprisoned a father in those lands,

have also driven the family into exile, you may get fifty where an Englishman's confinement in Whitecross street has plunged his wife and children into what are worse than a thousand exiles—starvation and despair. Individual suffering is undoubtedly greater in the state dungeon; but spreading, gathering, goading privation and misfortune—emigrating as it were from the actual prison into the great heart of society, and poisoning the social springs of life,—take their rise and go abroad from the Debtors' Gaol.—[Scenes, &c. by a Clergyman.]

**The Tower of Skulls.**—They took us to see a most remarkable edifice, called Burjer Roos, which as its name implies, is a tower entirely constructed of human skulls, reposing in regular rows, on intervening layers of the bones of the appertaining bodies. This curious tower stands close to the sea, at a little distance from the Fort, or Berjea-Sook, and is at present twenty feet in height, and at its base ten feet in diameter, but tapering to its summit: with these data, knowing what space is occupied by a skull, a calculation might easily be made of the number of men which were required to build it; though there appears no doubt that it was formerly, as the natives assert, much wider and higher. No tradition is preserved of its origin, except that the skulls are those of Christians. \* \* \* To preserve it, it is occasionally covered with a coat of mortar; but when I saw it, a great part of this had fallen down, and exposed to view the ghastly-grinning skulls.—[Temple's Excursions in Algiers.]

**Cheap Cure for Fever.**—A German doctor, during twenty-five years' practice, has never failed to cure intermittent fever, by strictly and literally starving his patients for three whole days. He allows them only a little water; and after the fast accustoms them to food gradually.

**WINE FROM THE COMMON BRAMBLE.**—Five measures of the ripe fruit, with one of honey and six of water, boiled, strained, and left to ferment, then boiled again, and put in casks to ferment, are said to produce an excellent wine.—[Receuil Industriel.]

Engineer Department of the New York and Harlem Railroad, May 23, 1856.

**TO RAILROAD CONTRACTORS.**—Proposals will be received at this Department until the 28th of May, for excavating a Tunnel through rock at Yorkville, from 18 to 24 feet in height, 24 feet wide, and 844 feet long.

For 15,000 yds. of Rock, and 8000 yds. of Earth, north and south of the same.

Proposals will also be received for making an Open Cut Excavation where said Tunnel is proposed, which, together with other excavations, will amount to about 66,000 yds. of Rock, and 12,000 yds. of Earth.

Plans and specifications will be furnished 10 days previous to the time above mentioned.

The work will be required to proceed immediately after being put under contract, and to be completed by the 1st of December, 1856. Satisfactory security will be required of the contractors for the faithful performance of the work.

Communications may be addressed to the Engineer, at his office, No. 9 Chambers street. By order of the Board of Directors, JOHN EWEN, Jr., Engineer, m2 235 of the N. York & Harlem Railroad Co.

#### **RAILROAD CASTINGS.**

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. B-1y 1614

#### **STEPHENSON,**

Builder of a superior style of Passenger Cars for Railroads,

No. 264 Elizabeth street, near Bleecker street, New-York.

**TO RAILROAD COMPANIES** would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J25 1f

#### **NOTICE TO MANUFACTURERS.**

**SIMON FAIRMAN**, of the village of Lansingburgh, in the county of Rensselaer, and state of New-York, has invented and put in operation a Machine for making Wrought Nails with square points. This machine will make about sixty 6d nails, and about forty 10d nails in a minute, and in the same proportion larger sizes, even to spikes for shingles. The nails are hammered and come from the machine completely heated to redness, that its capacity for being clenched is good and sure. One horse power is sufficient to drive one machine, and may easily be applied where such power for driving machinery is in operation. Said Fairman will make, vend and warrant machines as above, to any persons who may apply for them as soon as they may be made, and on the most reasonable terms. He also desires to sell one-half of his patent right for the use of said machines throughout the United States. Any person desiring further information, or to purchase, will please to call at the machine shop of Mr. John Humphrey, in the village of Lansingburgh. August 15, 1856. AD-25M&F

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, MAY 23, 1835.

The Report of Messrs. Jervis, Hutchinson, and Mills, is continued in this number.

**RAILROAD SHARES.**—We quote 105 for new, and 107 for old Shares, at which rate transactions to a considerable extent have taken place.—[Charleston paper, May 15.]

The Athens, Ga. Banner says: the annual meeting of the Directors of the Georgia Railroad Company was held in this place on Saturday last, and of the stockholders on the Monday and Tuesday following.

The following information is all we have yet been able to gather, relative to their proceedings, &c.

Three fourths of the stock was represented at the meeting. Among the stockholders, the very best feelings of liberality and unanimity prevailed, with regard to every thing touching the great work in contemplation, and for the early and efficient prosecution of which, liberal measures were unanimously adopted.

The Journal of the proceedings of the stockholders will appear in our next.

JAMES CAMAK, Esq. of this place, was re-elected President, General Superintendent and Treasurer; William Williams, Secretary; and the following gentlemen, Directors, for the current year, viz.: E. A. Nisbet and Adam G. Saffold, of Morgan Co.;

John Cunningham and Thomas G. Janes, of Greene Co.; Absalom Janes and Henry B. Thompson, of Taliaferro Co.; William Cumming, of Augusta; William Williams, John Nisbet, William Dearing, John A. Cobb, E. L. Newton, A. B. Linton, James Shannon, Wm. M. Morton, and Wm. R. Cunningham, of Athens.

Wm. Lumpkin, Esq., one of the former Board, declined a re-election.

**SYRACUSE AND AUBURN RAILROAD.**—A long and interesting letter from a gentleman at Auburn, has been handed to us,—accompanied by a letter from Mr. E. F. Johnson, Civil Engineer, who is now engaged upon the road,—from which we make the following extract, regretting that we have not room for the whole letter.

We publish this letter with a view of making the work to which it refers more generally known; that we may, if such aid availeth any thing, contribute our mite to its speedy construction. Knowing as we do, from long personal acquaintance, the great fertility and resources of the country through which it passes, and the almost unparalleled rapid growth of the flourishing villages at its two extremes, as well as the enterprise and respectability of those interested in its completion, we have not a doubt of its early construction, and ultimate success and value.

Auburn, May 9, 1835.

DEAR SIR,—In reply to inquiries so frequent and general of late, about the Auburn and Syracuse railroad, and its stock, we have requested our Chief Engineer to furnish us a statement, which is enclosed. It is cautious, as is proper it should be, he having just run over one of the proposed routes, and does not propose to settle any other question than the feasibility of the project, and upon that point it is abundantly satisfactory. To those who only know the ground, from having passed over the distance in the stage, it will be astonishing to find, that the difference between the average and maximum inclination is only 19½ feet per mile, about the same as that upon

the Utica and Schenectady Railroad, and less than that of the level part of the Mohawk and Hudson, and that the greatest inclination is 30 feet per mile for a distance of 1½ miles.

The engineer has not enlarged upon the benefits to the public or stockholders, but says that he is inclined to believe, "that the cost of transportation will not be much, if any greater than upon a road approaching near to a level (as the route examined does to an uniform inclination,) the curvature being the same upon both." The company has the privilege of carrying freight. The benefits, public and individual, were so obvious, to those acquainted with the vicinity and business, that it was found not to be necessary to go from the two villages with the stock to have it taken up, nor to attempt to attract attention from abroad. The whole stock was promptly taken up last fall, upon opening the books, by the inhabitants on the road, who have since sold, at an advance to capitalists, nearly or quite one-half. In estimating these advantages, the freight business (as known to the inhabitants of Auburn) of their own village, is a convenient and pretty appendage in the way of net profits. Not counting upon any increase of this business, as must necessarily be the case by the greater facilities of this road, the business of the Owaseo Canal Company, now in progress, and the exhaustless hydraulic power to be created for navigation and manufacturing purposes, by tapping the Owaseo lake; by the amount which will be naturally drawn to the road from the Cayuga, Seneca, Owaseo, and Skanateles lakes, and the fertile regions extending from 20 to 40 miles south of the whole line of the road, and also from the western region during the season of canal navigation, and particularly during the months from November to May, when that navigation is closed, not counting upon an increase of the freight business of Auburn, which is now about 10,000 tons, as estimated, annually, and, at a moderate estimate, will afford the company a profit of \$1.50 per ton, the subscribers here believed the freight privilege afforded them a security for an amount of profit or revenue, that would more than counterbalance any supposed difference of the passenger business in favor of the Utica and Schenectady road, over this section of the great thoroughfare.

I have made a long letter of this, because

little is known of this project away from home. The engineer and his corps are entirely engaged in ascertaining facts, and making a thorough examination, which will enable us to give more detailed information hereafter. It is designed to have the road complete for cars as soon as the Utica and Schenectady road is completed. I shall have answered generally all your inquiries when I add, that the capital stock is \$400,000—all subscribed in December last. The board of directors are, Elijah Miller, President; Nathaniel Garrow, Vice President; Asaph D. Leonard, Secretary; George B. Throop, Treasurer; Jno. M. Sherwood, Edward E. Marvine, Richard Steele, John Seymour, Allen Warden, S. Van Anden, Henry Raynor, V. W. Smith, and A. Fitch. Stock is transferable at the Treasurer's office at Auburn, and at the office of John Delafield, Esq. of New-York, who has been duly appointed the Register of Stock in the city of New-York.

[COPY.]

I have examined one of the proposed routes for the Auburn and Syracuse Railroad.

The distance by this route is 26½ miles, exceeding that by the turnpike about one mile. The greatest inclination is 30 feet per mile for a distance of 1½ mile. This occurs in the approach to the Nine Mile creek, on the west side, along the Windfall Valley. The total elevation of Auburn above Syracuse is 274 feet, making an average of 10½ feet per mile. The difference, therefore, between the average and maximum inclination is 19½ feet per mile, not much greater than the same difference on the Utica and Schenectady Railroad, and less than the same difference upon the portion of the Mohawk and Hudson Railway between the inclined planes, the greatest inclination upon which is 37½ feet per mile for 1½ miles, the average descent being 11½ feet per mile. So far, therefore, as it regards the inclination, the Auburn and Syracuse route is more favorable than the level portion, as it is commonly called, of the Mohawk and Hudson road, between the planes. The latter, however, has the advantage in straightness, which will lessen the difference. The portion of the Baltimore and Ohio Railroad, between Baltimore and Parr's Ridge, has an average descent towards Baltimore of 14½ feet per mile, and a maximum inclination in the same direction of 37½ feet per mile. The average is consequently 4½ feet, and the maximum 7½ feet per mile, greater than upon the Auburn and Syracuse road. The Amboy and Camden road is stated to have a maximum inclination of 45 feet per mile; this is however only a short distance, three fourths of a mile.

No estimate has yet been made of the probable cost of the road. It will not, however, I imagine, vary materially in proportion to its length, from that of the Utica and Schenectady Railroad, provided a similar plan of construction is adopted. The materials being near at hand, will probably cost less. The damages to turnpike and land proprietors, will undoubtedly be less.

As it regards the cost of transportation, it will be observed that the inclination is eastward, in the direction of the greater trade, the average descent being ten and a third feet per mile. This is perhaps a greater descent than would be required to suit the preponderance in freight, &c. Considering how great that preponderance must be, viz. 2 or 3 to 1, I am inclined to believe that the cost of transportation will not be much, if any greater, than upon a road approaching near to a level, as the route ex-

mined does to an uniform inclination, the curvature being the same upon both.

I would remark, in conclusion, that the ground between Auburn and Syracuse has not yet been fully explored. The route at present surveyed may not prove the best in every particular. No change will, however, it is presumed, be made, unless warranted by reasons affecting the cost of construction, or the cost or amount of transportation, and will, consequently, prove favorable rather than otherwise.

E. F. JOHNSON,  
Engineer of A. and S. Railroad.  
Syracuse, May 8, 1835.

*Report of John B. Jervis, Holmes Hutchinson, and Frederick C. Mills, to the honorable the Canal Commissioners of the State of New-York:*

(Continued from our last number.)

#### *Inclined plane at Liverpool.*

Length, 1.12 miles; rise  $\frac{1}{4}$ . The extra cost of the transit for moving power, taking the average from two semi-annual reports, is 1.90 cts. per mile, 2.02 cents for the total length, per ton; equal, for total cost of transportation, to 0.43 of a mile, on a level.

#### *Sutton and Whiston Planes.*

Are each 1½ miles long, and have an inclination of  $\frac{1}{8}$  or 55 feet per mile. They incline in opposite directions, and therefore, if the trade was equal in each direction, only one plane should be calculated as affecting the total transportation; as it is obvious, a load passing in either direction would only require additional power to ascend one plane. In the reports of the directors they give the total freight, not distinguishing between the different directions; and we are left to determine, from the general character of the trade, whether any and what difference there was. It appears that not more than  $\frac{1}{2}$  of the tonnage between the two cities passes on the railway; and we, therefore, are led to infer the railway takes the lighter character of freight, which is probably about equal in both directions; and our computation of costs is made on this basis.

This road being worked entirely by locomotive steam power, except the inclined plane at Liverpool, which has stationary power, our computation is made accordingly.

In ascending the plane the resistance will be  $\frac{1}{8}$ , (friction,)  $+\frac{1}{4}$ , (gravity,)  $=\frac{3}{8}$ , or ratio to a level of (.375 to 1,) or a little more than three and one-third to one. The power of the engine will be reduced by its gravity, and that of its tender, to 70 per cent. of its power, on a level; or to make it equal its power on a level, it must be increased to 142 per cent., which makes the cost of moving power to ascend the plane, as compared with a level, as 4.75 to 1, or four and three-fourths to one. The extra moving power to ascend this plane over a level is equal to the transit of 5.62 miles on a level. The moving power is 26 per cent. of the total transportation, exclusive of the interest account, in which the items of moving power and wagons are blended; this will not be less than 4 per cent., making the total cost of moving power at least 30 per cent. The extra cost of the planes are therefore equal 1.63 miles entire transportation on a level.

The greatest inclination on any part of this railway, except the inclined planes above mentioned, is  $\frac{1}{8}$  or 6 feet per mile. It is presumed the ascent of this inclination will regulate the load of the engines, on

which the resistance will be  $\frac{1}{8} + \frac{1}{4} = \frac{3}{8}$ , or ratio to a level of 1.25 to 1. The power of the engine will be reduced by its gravity and that of its tender to 97 per cent., or its power must be increased over what would be required on a level; say to 104 per cent., making the cost, as compared with a level, as 1.50 to 1. This will be applicable to 27 miles of road, on which the extra cost for moving power is equal 8.1 miles, or for entire transportation equal 2.43 miles.

The influence of the elevations on this railway in increasing the cost of transportation over that of a level, is  $(4\frac{3}{4} + 1.68 + 2.43 = 4.54)$ , a little more than four and half miles of level way. The actual average cost of transportation for 31 miles was found to be (4.7,) nearly four and three-fourths cents per ton, which, reduced to a level road, we find to be (4.07,) over four cents per ton, per mile.

An increasing fact is developed in this investigation, in relation to the comparative cost of transportation on inclined planes by stationary and by locomotive steam engines. The plane at Liverpool is worked by stationary steam power, and has an inclination of  $\frac{1}{4}$ , or 100 feet to the mile. The Whiston and Sutton planes, worked by locomotive steam power, have an inclination of  $\frac{1}{8}$  or 55 feet in a mile, being exactly half the inclination of the Liverpool; yet the cost of moving power on the Liverpool to Whiston or Sutton is as 1 to 2.90; showing that locomotive power, for an ascent of 55 feet to the mile, is about three times the expense of stationary power for a plane 110 feet to the mile, calculated for equal horizontal distances. It should be observed, in relation to this fact, that economy of stationary power on inclined planes depends materially on the amount of business. In this case it was about 500 tons per day.

#### *Baltimore and Washington Railroad.*

This road commences at a point in the Baltimore and Ohio railroad, about 6 miles from Baltimore, and extends 30 miles to the city of Washington. Its operations are conducted by the Baltimore and Ohio company. In their report of October, 1833, they state the estimated cost at a little over \$55,000 per mile, for 26 miles. The estimate for the whole 30 miles is given at \$50,000 per mile, in a report on canals and railroads, as presented, 25th June, 1834, to the House of Representatives in Congress. In their report of October, 1834, the directors say the graduation and masonry, (the part of the expenditures liable to the principal contingencies,) is nearly completed; they make no allusion to the probability of the work costing more or less than the estimate; and as it would be natural to do so, if any important disagreement was probable, it is inferred the road would cost the estimated sum; and being so near completed, we have thought it proper to put it in the table. This road has iron rails on stone foundation, except the embankments, which have timber foundation.

#### *Columbia Railroad.*

This railroad is 82 miles long, and per last report of the Pennsylvania commissioners, the road has cost, including an estimate for an unimportant amount of unfinished work, \$40,450 per mile. It has mostly iron rails, partly on stone and partly timber foundation.

#### *Allegany Portage Railroad.*

This railroad is 36 miles long, and per report of Pennsylvania commissioners, has cost, including a small estimate for unfinished work, \$47,977 per mile. It has iron rails for a fraction over two-thirds its

length, about half of which are on stone foundation, and the balance on timber; nearly two-thirds is timber road with iron plates.

*Mohawk and Hudson Railroad.*

The main stem of this road is 16 miles in length. It has timber rails with iron plates, about half of which are on a stone foundation, and the other half on timber. Cost per mile of double road, \$38,107, per company books. (They have also about 3½ miles of single road in branches, that cost \$15,847 per mile.)

Actual cost of transportation for freight by locomotive and stationary steam, 3.5 cents per ton per mile. All the ascent for the greatest trade, (being as 3 to 1,) is overcome by one stationary engine, which does not materially enhance the ratio of cost over a level, taking the whole road. Experience has been quite limited on this road, and considering that the ratio of trade in different directions, in connection with the facility of overcoming the principal elevation by stationary power, would not materially increase the cost of transportation over a level, it has not been thought important to reduce it by computation. The cost of transporting passengers has been 1.7 cents per mile.

*Saratoga and Schenectady Railroad.*

This railroad is 22 miles long. It is constructed with a timber rail, capped with an iron plate, on timber foundation, except about three miles, that has a light stone foundation. This road has a single track; its cost, per report of directors, November, 1832, \$11,010 per mile, exclusive of building, &c.; to make a second track of the same character would cost \$6,000, making the total cost for double road \$17,010 per mile.

*Delaware and Hudson Canal Company Railroad*

Is 16 miles long, has 5 mile of double and 11 miles of single track. The valleys on this road were generally bridged with timber. The road is timber with an iron plate. It cost originally, including stationary engines, about \$10,500 per mile, (the exact amount not known.) To have made it double would have raised the expense to \$14,000 per mile; average annual repairs for four years is \$625 per mile. Transportation, when the business is at 250 tons per day, is 4 cents per ton per mile, and when 500 tons per day, is 3 cents per ton per mile. This arises mostly from the cost of operating the planes, which is nearly the same in both cases.

The ascent of this road (855 feet) is overcome by five stationary steam engines, working on planes whose total length is 2½ miles. The cost of motive power for 500 tons per day, averages essentially the same as it does for horse power on a level, having the same in horizontal length. From the summit the principal descent is effected by three self-acting engines, so arranged that the loaded waggons draw up the empty ones: and the balance of the declivity is advantageously arranged for a descending trade. The economy in the use of stationary steam power, arising from the cheapness of fuel, and the great regularity which may be obtained in a coal business, and the comparatively small amount of agencies to conduct the business, leave no doubt on our minds, that transportation is effected on this road as cheap per ton per mile as a general business could be on a level road.

*Newcastle and Frenchtown Railroad*

Is 16 miles long; timber rail capped with

iron plate, about one-third on light a foundation, and the balance on stone. Cost \$30,000 per mile. (See report of a committee on roads and canals to Congr January 25th, 1834.)

*Camden and Amboy Railroad.*

The part extending from Amboy to 1 dentown is 33 miles in length, is believed to be entire iron rail, partly on stone, partly on timber foundation; cost (as congressional report above mention) 30,000 per mile.

*South Carolina Railroad.*

Is 130 miles long; timber rail cap with an iron plate. This road is built on piles; no embankments made in the grading; cost about \$7,000 per mile. It is known whether it is a single or a double road, but believed to be mostly single track.

There are several important railroads in the United States, which we should have been gratified to have added to those above given. But we have not the information relation to them, that would enable us derive any practical advantage. There are others that we have not thought proper to introduce in a question that relates to general utility of railroads as public thoroughfares: they are roads made merely for local objects, or for short distances where the surface of the ground is not level, and the road made to conform to the natural level or inclination, and a little expense incurred to remove those regularities in the surface, which in a road of any considerable length and importance are generally encountered, to obtain an economical grade: and the superstructure such roads is usually made in an imperfect manner, not calculated to serve the purpose of accommodating an important general trade.

In the roads described, it is believed a view may be obtained of the general question of cost. In their graduation some have been of an expensive character, to wit: Baltimore and Washington, Alleghany Passage, the Columbia, Mohawk and Hudson, and a part of the Baltimore and Ohio; though on the average the latter cannot much above medium: the Camden, Amboy, and the New-Castle and Frenchtown, rather below a medium, and the Saratoga as very favorable. The South Carolina road having been placed on piles, cavation has been avoided as much as possible, and embankments omitted altogether by which the expense of grading has been very little. The general character of superstructure has been stated; and of rails, or the foundation of the rails, applicable, to a great extent of timber.

The superstructure of railroads, when composed of timber with the rail cap with an iron plate, will cost, for a double track, from \$6,000 to \$10,000 per mile, according to the value of timber, and the facility given to the road; this is exclusive of grading. The cost on the Baltimore and Ohio, for this kind of road, was \$9,000 per mile. When composed of iron rail laid on stone foundations, the cost will vary from 18 to \$25,000, according to the convenience in obtaining stone, the extent of the ballasting, and the weight of rail to be adopted; the probable average will be \$22,000 per mile. The difference, then, between a medium of the two kinds, is \$14,000 per mile. To have adopted iron rail on a stone foundation in the road mentioned, would have materially increased their average cost. But in the first construction, it is usual, even when iron is adopted, to put down a timber foundation.

and \$40,000 per mile. Taking all the railroads designed to accommodate a large general trade that have been constructed in this country, and add to their expense what would be required to complete an iron rail with stone foundations, we believe the cost for a double road would not fall below \$35,000 per mile; and to reduce the same to a timber road of the best character, would not be less than \$25,000 per mile. The grading in both cases is supposed to be done in a permanent manner. We are aware of the fact, that railroads, in some instances, have been made for much less; but for the reasons before given, we do not believe them entitled to a place in this examination, which is designed to investigate the utility of railroads as a means of general intercommunication of trade. There are, no doubt, many situations where the favorable formation of the country, and the facilities for obtaining materials, will reduce the cost below the amount stated above, and a less expensive road may be sufficient for the trade to be accommodated. But there will be others that will be more expensive, as experience has fully demonstrated; and our object is to reach an average result for the accommodation of a general trade, where expedition, regularity, and economy in the moving power, will be important. It should be observed in relation to this question, that the cost of a railroad will depend materially on the amount of tonnage, and the speed it is necessary to maintain. This arises from the economy of motive power; for instance, where a small amount of business is to be accommodated, it will be economy to apply greater motive power, and avoid expensive graduation; on the other hand, a large amount of trade will induce greater expenses in bringing the lines of graduation to the most favorable standard for economizing this power.

#### *Remarks in relation to repairs on Railroads.*

Experience on this point is yet quite limited. We have the account of two years on the Baltimore and Ohio road, four years on the Delaware and Hudson company road, and four semi-annual statements of the Liverpool and Manchester road. We have also, in relation to the latter, a general statement of the half year preceding and the half year subsequent to the four full reports, from which we are led to infer that no material variation occurred for three years. The average of the three roads is \$1,040 per mile per annum.

There is a great difference in the annual expense of repairs for these roads, which suggest the propriety of examining into the cause.

The moving power on the Baltimore and Ohio, and also on the Delaware and Hudson company's road, admitted, for freight, only a moderate speed, probably seldom exceeding 4 miles per hour, and nearly the same amount of tonnage was conveyed on each: on the latter, no passengers are carried; on the former, the passengers constitute about half the business.

The Baltimore and Ohio road has less timber in its structure, though it has a large majority of timber road. The Delaware and Hudson Company road is about  $\frac{2}{3}$  single track, and considering the passenger business has not over half the use, and still its repairs are more than 50 per cent. higher. Two years, with a moderate amount of trade, on a timber road, would not give a fair average of the cost of repairs, and the condition of the two roads at the end of the year, in regard to the age and durability of their timber, may be very different. We are, therefore, led to conclude that further

experience will show the repairs on the Baltimore and Ohio road, as the business increases, to be greater than they have hitherto been.

The Liverpool and Manchester road has cost over five times as much for repairs as the Baltimore and Ohio, and over three times as much as the Delaware and Hudson Company road. The Liverpool road was made in the most substantial manner, with very little curvature. The Baltimore road is very much curved, which increases the expense of maintaining the parallelism of the rails. The statement of the cost of repairs and maintenance by the directors of the Liverpool road is very explicit, and continued for successive terms with very little variation; leaving no ground to misunderstand the subject. The amount of business on the Liverpool has been from three to four times as great as on the Baltimore, for equal terms of time; and the velocity of travelling, both with freight and passengers, has been also much greater on the former than on the latter. In view of all the facts we have obtained, we are led to the conclusion, that the amount of business, and the velocity of travelling, has a material influence on the question of repairs. In the last report of the directors of the Liverpool road, they allude to the expense of maintaining their road on the Whiston and Sutton planes, in consequence of the high velocity which the engines and wagons often obtain in their descent; and propose to lay heavier rails to guard against this inconvenience. In a report recently made to the directors of the London and Birmingham railway, by R. Stephenson, (late engineer of the Liverpool road,) on the propriety of adopting the undulating plan, he urges, as an objection to this plan, the injurious tendency of the high velocities obtained in the descents to the road and particularly to the locomotive engine, as a reason that he considers conclusive against it.

The repairs of a railroad composed mostly of timber will generally be much less for two or three years after it is put into operation, than the average for a term of ten or fifteen years. Our experience is limited in this branch of the investigation, but from the facts we have obtained, we are led to the conclusion, that the average expense of repairs for a road, designed to accommodate a large general trade requiring a high velocity, will not be less than that stated as the average of these roads, viz: \$1,040 per mile per annum.

#### *Transportation on Railroads.*

The cost of transportation (reduced to a level road,) on the Baltimore road, we have found to be 3.05 cents per ton per mile, and 4.07 cents per ton per mile on the Liverpool road. In the former case, it is done by horse power; in the latter, by locomotive (except on one plane,) steam power. The ratio of cost of motive power to the entire cost of transportation is for the Baltimore as 4 to 10; and for the Liverpool road, as 3 to 10. It, therefore, appears, that the Liverpool road, with 10 per cent. less ratio in cost of motive power, (which makes the motive power nearly equal on the two roads,) costs one-third more for entire expense of transportation. If our accounts can be relied on as presenting accurate results, it would appear highly probable the extra expense in repairs and management of the business, was incurred in consequence of the greater speed maintained. Some abatement should doubtless be made, for the ratio of difference in expense of loading and unloading, which, in consequence of its being shorter, would bear heavier on the Liverpool road than on

the Baltimore. The accounts for the Liverpool transportation are presented in much detail, and are very satisfactory in their character. Those for the Baltimore road are not given in as much fullness and detail, but we have no reason to doubt their accuracy. It further appears, that horse power is a little more expensive for motive power, at a low velocity, than locomotive steam, at a high velocity, as compared for the two roads. But this would not be the case if the power was reversed for the two roads, as the short ascents on the Baltimore road would greatly depress the economy of steam power. The average cost of transportation on these two roads, when reduced to a level, is 3.56 cents per ton per mile. This allows no profit or toll; the cost stated for the Mohawk and Hudson road is 3.5, and for the Delaware and Hudson Company's road is also 3.5 cents per ton per mile, as the nett cost. It may, therefore, be considered that experience thus far has settled the cost at  $3\frac{1}{2}$  cents per ton per mile, on a level road.

It has been shown in this investigation, that where locomotive steam power is used, it is important to its economy, to have all the inclination reduced to a uniform angle, and the curves to a uniform radius, otherwise the traction that occurs on the sharpest curves, and greatest ascents, will determine the load of the engine. It is obvious that the load of the engine must be regulated by its ability to overcome the greatest resistance that occurs on the road over which it passes, unless extra power is stationed on the line to aid in passing ascents: the inconvenience of stationary power would prevent a resort to this method, unless the increased power required was considerably greater than was generally necessary on the route travelled. This consideration is highly important where a large general trade is to be accommodated, and accounts for the great expense that is often encountered to bring the grade to the most favorable standard.

The cost has been shown to be  $3\frac{1}{2}$  cents per ton per mile on a level, and as railroads are not often entirely level, it has been thought proper to a full understanding of the subject, to present a statement, showing the comparative economy in motive power by locomotive steam engines on roads of different inclinations. In the calculations, the engine is assumed to weigh  $6\frac{1}{2}$  tons (13,000 lbs.) with 7,000 lbs. on its working wheels; adhesion at 10; the weight of the tender at 7,000 lbs.; resistance from friction  $\frac{1}{17}$ . The load carried is exclusive of the tender, and includes freight and wagons. Two-thirds of the gross load will be tonnage goods.

On a level the gross load will be 75.25 tons; on a road or section, having an ascent of 10 feet per mile, 49.53 tons—do. 20 feet, 37.35—do. 30 feet, 27.24—do. 40 feet, 20.22—do. 50 feet, 17.04—do. 60 feet, 13.92—do. 70 feet, 11.31.

In the load on a level, we have 50 tons exclusive of wagons, taking the cost of motive power at 40 per cent. of the entire cost of transportation; the total cost at the level being  $3\frac{1}{2}$  cents.

The total cost on an ascent of 10 feet per mile is per ton, 4.20 cts.—20 feet, 4.90—do. 30 feet, 5.95—do. 40 feet, 7.25—do. 50 feet, 8.19—do. 60 feet, 9.66—do. 70 feet, 11.41.

There are engines of a larger size than the one assumed; but it is the most approved at this time, in reference to the weight of engine, and the weight of the working wheels. This however is unimportant, as the comparison will not be at all affected by varying the power of the en-

gine: the ratio between a level and the ascents will remain the same notwithstanding.

#### Costs of Canals.

We subjoin a table marked A, containing the cost of 50 canals in England: this table gives the name of each canal, the total cost in pounds sterling, cost per mile, length of each canal in miles, lockage in feet, date of completion, original cost for each share, and the value and dividend of each share in 1821, in March 1828, in November 1831, in 1833, and on the 21st of October, 1834. Forty-five of these canals, being the most important in England, have an aggregate length of 1,464 miles. We also subjoin a table of the principal railways; only one, however, of those which are completed and in operation, (the Liverpool and Manchester,) is calculated for general trade.

In table B, we give a view of the principal canals in this country: it contains all the particulars that we were able to obtain of 40 canals, principally in the northern and middle States. It has the names of the canals, the length of the main trunk and feeders, depth of water, width of surface, number of locks, their length and width, and the aggregate lockage on the canals and feeders, number of dams, date of completion, cost per mile, total cost, and the tolls for each for the years 1833 and 1834.

The information contained in the tables for the canals of this State was obtained from public records and from documents in the Comptroller's office. That for the Pennsylvania and the other canals were taken principally from the official reports, and from information derived from the officers having charge of these canals respectively; we have also been assisted in the inquiries by private records and memorandums in our possession.

The Erie canal extends from the Hudson river at Albany to Lake Erie; is 363 miles long, and has 690 feet of lockage; the canal is 40 feet wide on the surface, 28 feet wide at the bottom, and four feet deep. The locks are 90 feet long, between the gates, 15 feet wide, and built principally of lime stone, laid in hydraulic cement, with the front stone cut and laid in courses. Although there is a small amount of elevation, compared with the distance, but at 1½ feet of lockage per mile, there are a few places that presented formidable difficulties in the construction: a part of the distance between the Hudson and Schenectady, the rock excavation at Little-Falls, and the deep-cutting in the mountain ridge west of Lockport.

The Champlain canal is the same dimensions as the Erie canal; the locks are constructed in the same manner, except they are 7 feet longer, and one foot less width. This canal is 64 miles long, and extends from the junction 9 miles north of Albany to Lake Champlain. The summit is supplied with water from the Fort Edward pond, and by a navigable feeder from the Hudson river, taken out above Glen's-Falls.

The Glen's-Falls feeder is 7 miles long, and with the pond, makes a navigation of 12 miles in length; there is a descent of 132 feet by 13 wood locks.

The Oswego canal is constructed similar to the Erie canal, but has nearly one half river navigation. The locks are of the same dimensions and quality, except one, which is built of wood.

This canal extends from the Erie canal at Syracuse to Lake Ontario.

The Cayuga and Seneca canal is, with the Cayuga branch, 23 miles long, connects

the Erie canal at Montezuma with Seneca lake at Geneva, one half of which is river navigation. It has 11 wood locks, that overcome an elevation of 80 feet. The dimensions of the canal and locks are similar to those on the Erie canal.

The Crooked Lake canal is 8 miles long, connects the Crooked and Seneca lakes and has 260 feet of lockage; this, although the locks are of wood, is the most expensive of the State canals; the large expenditure is accounted for by the great elevation overcome, and by the difficulties in construction in the narrow rocky valley of the outlet.

The Chemung canal extends from the head of the Seneca lake to the Chemung river: it is 23 miles long, and the summit is supplied by a feeder of 13½ miles in length, from the Chemung river, at the Chimney Narrows in Steuben county. This canal and feeder, (as also the Crooked Lake canal,) is 42 feet wide on the surface, 26 feet wide on the bottom, and four feet deep; the locks are of wood, connected with the upper level by a wall of masonry at the head. The length of navigation, including 2½ miles of pond in the Chemung river above the feeder dam, is 39 miles, with a lockage of 516 feet, and is the cheapest of the State canals.

The Erie canal cost	\$19,255 49 per mile.
Champlain	15,520 95 "
Oswego	14,879 93 "
Cayuga and Seneca	10,295 85 "
Crooked Lake	19,597 11 "
Chemung	8,504 96 "

The aggregate cost of the six State canals, paid by the Canal Commissioners, for their construction up to the time when they were completed, for the 556 miles of navigation, is \$9,692,106.68, being an average cost of \$17,367.57 per mile.

The Delaware and Hudson canal extends from the Hudson river, near Kingston, to Honesdale on the Lackawaxen river, in the State of Pennsylvania. This canal is 108 miles long, 36 feet wide on the surface of the water, and four feet deep. The locks are 76 feet long, nine feet wide in the chamber, 110 in number, and overcome an elevation of 1,073 feet: 60 of the locks are of hammered stone masonry, and 50 are composite, of stone and wood.

There was some formidable rock excavation in the valley of the Delaware and Lackawaxen rivers, which increased the expense of construction. The average cost of this canal was \$20,665 per mile.

#### Pennsylvania Canals.

The Pennsylvania State canals are divided into 9 divisions, and they have an aggregate length of 601½ miles. The main line of these canals form a communication in connection with the Columbia and the Portage railroads, between Philadelphia and Pittsburgh. Between these places there are 282 miles of canals and 119 miles of railway.

The Delaware division extends from Bristol to Easton, 59½ miles; and in the valley of the Susquehanna, including the west and north branch, there are 183 miles of canal, besides the Beaver and French creek divisions, west of the mountains. These State canals have 1,933 feet of lockage, and their total cost is \$13,301,235.69, or an average of \$22,113.43 per mile.

Beside the State improvements there are three important canals in Pennsylvania owned by corporations, viz: The Schuylkill, the Lehigh and the Union canals.

The Schuylkill canal extends from the city of Philadelphia up the river of that name, 108 miles, to the coal district. This work has 62 miles of canal and 46 miles of

pools, formed by 28 dams across the Schuylkill river. There are 92 lift and 28 guard locks, and the total lockage is 588 feet. This canal was completed in 1825, and the business upon it has increased so rapidly that it has been necessary, and the directors are now constructing double locks to accommodate the trade. At its completion (in 1825,) the canal cost \$16,741.26 per mile.

The Lehigh canal was constructed principally for the transportation of coal, and extends from Mauch Chunk to Easton on the Delaware river, 46½ miles. This canal is 60 feet wide on the surface and 5 feet deep; the locks are 100 feet long (except 4, which are 130,) and 22 feet wide in the chamber; and its large dimensions have, doubtless, added much to its cost.

Coal that is brought from the Lehigh mines down this canal, may be sent to Philadelphia by the Delaware canal, or to New-York through the Morris or the Delaware and Raritan canals. This canal cost \$33,610.75 per mile.

The Union canal connects the Schuylkill and Susquehanna rivers; this, although a small canal, 36 feet wide on the surface of the water, and 4 feet deep, has been expensive in construction. Connected with this canal is a feeder of 24 miles in length, to supply its summit level. This feeder is navigable, and a railroad of 4 miles in length extends to the coal mines. A large expenditure has been incurred to construct reservoirs, 3 feeders, and for the use of two steam engines, of 100 horse-power each, to supply the summit level with water, and for several miles the sides and bottom of the canal have been planked, to prevent leaks in the lime-stone districts. This canal cost \$18,518.51 per mile.

The three canals have 1,452 feet of lockage, and cost \$5,354,151.13, and the average cost of the 262½ miles is \$20,377.36 per mile.

The State of Ohio completed their canal, from Lake Erie to the Ohio river, in 1832, which, together with the Miami canal and feeders, make an aggregate of 400 miles of navigation. The total amount of lockage is 1,557 feet; the locks, 184 in number, are constructed of cut stone laid in hydraulic cement; and the total cost of the canals and appendages, as appears in the Canal Commissioners' report of 1833, is \$4,189,539.64, or an average of \$10,473.84 per mile.

The Chesapeake and Ohio canal will form a communication from the City of Washington, 342 miles in length, to Pittsburgh. That portion nearly completed and navigable extends from Tiber creek, in Washington city, 109 miles to a point 8 miles west of Williamsport. This canal varies from 5 to 7 feet in depth, and from 50 to 80 feet in width; the ascent is 353 feet, overcome by 44 lift locks 100 feet long by 15 feet wide in the clear, constructed of cut stone masonry laid in hydraulic cement.

This canal is situated in the valley of the Potomac; it is of large dimensions, and formidable difficulties have been encountered in its construction. The amount expended and required to complete 109 miles is \$4,164,732.04, or an average cost of \$37,291.12 per mile.

There are five canals in New-England, having an aggregate of 170½ miles in length, with 1,363½ feet of lockage, constructed by private corporations at an expense of \$2,187,000, or an average of \$12,838.71 per mile. The Blackstone canal between Worcester and Providence, of 45 miles long, has 48 locks of cut granite, laid in

element; the other four canals have wood locks.

Three of the canals embraced in the tables are of large dimensions, and were constructed of suitable capacity for the navigation of coasting vessels.

These canals connect the great bays of the Atlantic, as follows, viz: The Bismar Swamp, between Albemarle sound and the Chesapeake bay; the Delaware and Chesapeake canal, across the peninsula between

The last results, as do also the comparisons of former years, indicate that the expense of the repairs of the Erie canal increases in nearly the same ratio as the business.

The repairs on the Delaware and Hudson canal, for the last 4 years, ending December 31, 1884, was an average of \$527 per mile; and for the year 1883, including the salary of superintendents and lock-tenders, on the Schuylkill canal, was \$710.44 per mile.

#### Cost of transportation on Canals.

In this inquiry we have selected three canals that have a large amount of business and those that have their prices well established.

The Erie canal, and the Delaware and Hudson canal, in this State, and the Schuylkill in Pennsylvania. We are not able to give the items that compose the cost of freighting upon canals, with the same certainty as that expense has been reported by the Liverpool and Manchester, and the Baltimore and Ohio Rail Road companies; but we assume the prices, paid on canals for down freight, upon articles of the greatest tonnage.

The Schuylkill canal in 1833, had 361,064 tons of down freight, of which 250,558 was coal from the mines; and the up freight, consisting of merchandize, plaster, iron ore, &c., amounted to 84,795 tons. The price for the transportation of coal is one cent per ton per mile, exclusive of tolls.

The Delaware and Hudson Canal Company, in 1833, sent to market from the mines, 111,777 tons of coal, and the merchandize up amounted to 9,700 tons. In

the Hudson river was established price of transportation per ton of 2,240 miles by this canal, Hudson river, equal

miles. At tide water, by canals, in 1834, as statements, was equaling from tide water an aggregate of 668,

433 do. The proportion of down freight or property going to market, is to merchandize or tonnage going from tide water, as 4.83 to 1, or as 5 to 1 nearly.

The cheapest prices of freight on the Erie canal are paid for staves, timber, wood, stone, lime, plaster and salt; the highest charges are for merchandize. We put down the rates, exclusive of tolls, as charged by the different forwarding lines, although goods are frequently taken up the canal by boats unconnected with the lines, at about half those rates; this higher price is intended, besides the cost of freighting, to pay for the risk to which the forwarding merchant is liable as a common carrier.

During the season of navigation last year, there was brought down the canals, 32,670 tons of staves, and we are informed, that the average price of transportation of this article has been \$2 per ton for the last 6 years, from Tonawanda to Albany, exclusive of tolls. The distance is 352 miles by the canal, and this would give only  $\frac{1}{17}$  of a cent per ton per mile.

There was also sent down—181,016 tons of boards and scantling, at  $\frac{1}{10}$  of a cent per mile; 96,842 do. of wood, do. at  $\frac{1}{10}$  do.; 23,894 do. salt, to Buffalo passing Utica, at  $\frac{1}{10}$  do.; 70,372 do. merchandize do. at  $\frac{1}{10}$  do.

Making an average of the above prices, of  $\frac{1}{10}$  of a cent per mile for a ton of 2,000 pounds.

Flour is a large item of the down freight;

there is about 120,080 tons sent to market annually, and this, together with provisions, may be taken as a standard of comparison.

Flour has been carried from Rochester to Albany, 289 miles, by transient boats, as low as 18 or 20 cents per barrel, exclusive of tolls; we are informed, however, that contracts for freight to a large amount have been made by millers at Rochester, with the established lines of forwarding merchants, for the ensuing year, at 24 cents per barrel, from the first of June to the first of October; before and after these periods, at 30 cents per barrel for flour, exclusive of tolls.

For this comparison we will take an average between these two prices, which is 27 cents per barrel, and this is believed to be about the average price paid for freight on the whole tonnage of the Erie canal during the season of navigation.

At the above rates the prices of transportation on the three canals, exclusive of tolls, would be, for a ton of 2,240 pounds, as follows, viz: on the Erie canal, 1.04 cents per ton per mile; on the Delaware and Hudson, 1.041 do.; Schuylkill, 1.00 do.; or an average of a little over one per cent. per ton per mile, on the three canals.

For a more perfect comparison of the cost of transportation, we will reduce these canals to a level, by an allowance of 20 feet of lockage on the Erie and Schuylkill, as equal to a mile of distance, and in consequence of the less crowded navigation, of 30 feet to the mile on the Delaware and Hudson canal.

The distance on the Erie canal from Rochester to Albany, is 289 miles, and the lockage 626 feet, and reduced to a level would be equal to 300  $\frac{1}{2}$  miles.

The Schuylkill canal is 106 miles long, and 588 feet of lockage, and reduced to a level in the above mentioned ratio, is equal to 137  $\frac{1}{4}$ -10ths miles.

The Delaware and Hudson is 106 miles long, and has 1,073 feet of lockage, and is equal to 183  $\frac{8}{10}$ ths miles level canal.

On a level canal, the prices of freight would be for the Erie canal 828-1000ths of a cent per ton per mile; Schuylkill 738-1000ths do.; Delaware and Hudson 708-1000ths do.; and the average price of the three canals would be, without toll, 788-1000ths, or a little less than 8-10ths of a cent per ton per mile.

In Hazard's Register, vol. 15, page 112, it is stated that the Lehigh, the Delaware, and Delaware and Raritan canals, paid last year 2-10ths of a cent per ton per mile, for the transportation of 105,000 tons of coal; the contractor finding every thing, except paying the tolls.

#### General Remarks.

Having presented such facts as are within our knowledge, with the circumstances connected with them; together with such explanations of principles, as appeared to us necessary to a correct understanding of the subject in its practical character, we have not thought it would aid in the object of inquiry, to attempt any precise ratio of comparative cost of construction or repairs, between canals and railroads: the reason for this is to be found in the obvious modification to which any ratio must be exposed, in the varied local circumstances that will be encountered, in the progress of improvements of this character, and whose tendency would render any ratio of little or no practical value. We, therefore, refer to the several statements, and particularly the tabular views, for information, which we believe, when applied to any known case, will afford some useful hints in regard to the relative merits of the two different modes of facilitating internal communication. We

The following table exhibits the length, lockage, and cost of some of the principal canals.

Canal	Miles	Locks	Cost per mile	Total
1. N. York & Albany	588	2	17	9,993,168 00
2. Del. & Hudson	106	1	10	2,211,890 00
3. Schuylkill	106	1	10	2,211,890 00

By the preceding table it appears that 27 of the principal canals of this country, having an aggregate length of 2,210 miles, with 9,746 feet of lockage, embracing many difficulties, and constructed in nine of the United States, in a great variety of locations, have cost \$41,122,585.18, or an average of \$18,608.41 per mile.

Subsequently, in 1880, were \$12,425; in 1884, were \$33,011. An increase of 50 per cent.

may, however, be permitted to state, what appears conclusive from the facts presented, that canals, on the average, have thus far cost less than railroads, both in their construction and repairs.

In regard to their relative merits as affording the means of transportation, there is less difficulty in reaching an approximate ratio. In reducing them both to a level, we attain for general purposes, a fair standard of comparison. Taking the facts we have obtained as a basis, we find the relative cost of conveyance is as 4.375 to 1, a little over four and one-third to one, in favor of canals: this is exclusive of tolls or profits. If the cost of construction, the annual cost for repairs, and the amount of tonnage, were the same on a canal as on a railroad, then the same rate of toll would produce the same rate of profit on each. Our examinations have shown, as before stated, that railroads in the average, cost more than canals, both in their construction and repairs. But for comparison, we assume a case in which they are equal, and charge the same toll. The average tolls on the Erie canal are less than one cent per ton per mile: assuming an average toll of one cent per ton per mile, the ratio of the entire cost of transportation and toll is, as (2.5 to 1,) two and a half to one, in favor of canals. In the preceding computations, the cost of transportation on railroads is the net cost, as reported by railroad companies, allowing no profit on this business, while the charges on the canals is at contract prices, which are supposed to yield a profit to the carrier. The cost of transportation on canals, as previously stated, is the average on the Erie canal, the Delaware and Hudson canal, and the Schuylkill canal; on the two latter, the cost of transporting coal only is known; and the total average of the three canals is almost exactly the same as the average price for the several different articles transported on the Erie canal. The preceding calculations are confined to a velocity not much exceeding 50 or 60 miles in 24 hours. We have not instituted any investigation to show the relative economy in high and low velocities. For the conveyance of freight, we are of the opinion, canals are not well adapted to any material increase of speed beyond 3 miles per hour; and as they proceed on half of the railroads embarking on this computation is from 10 to 15 miles per hour, we may consider this comparison as nearly similar to one of high velocity on railroads, and low velocity on canals. And goods that can afford to pay the difference above indicated, for the saving of time, would hold the two kinds of conveyance in equilibrium. The amount that would find so great an object in the saving of time, in comparison to the total quantity requiring transportation, it is believed would be small. In relation to the conveyance of passengers, the saving of time is highly important, and the railroad becomes eminently the superior method of communication. We are, therefore, led to the conclusion, that in regard to the cost of construction and maintenance, and also in reference to the expense of conveyance at moderate velocities, canals are clearly the most advantageous means of communication. On the other hand, where high velocities are required, as for the conveyance of passengers, and under some circumstances of competition, for light goods of great value, in proportion to their weight, the preference would be given to a railroad.

It may be objected in favor of railroads, that they admit of advantageous use in districts where canals, for the want of water, would be impracticable. This advantage often occurs in mining districts, and some-

times for general trade, where it is necessary to cross dividing ridges at a level too high to obtain water for their summits.

The facts and reasonings presented, we believe, clearly show that both canals and railroads are highly important means of internal communication; that each has its peculiar advantages, and will predominate according to the character of the route, and the trade for which it is intended to provide.

Respectfully submitted,

JOHN B. JEWELL,

HOLMES HUTCHINSON,

FREDERICK C. MILLS,

Civil Engineers.

Albany, 14th March, 1835.

[From the National Intelligencer.]

THE ALLEGHENY ARSENAL.—Pennsylvania can boast of finest and say the workmen 'Allegheny United' nance of thirty and one above road, and built we vid is 1st. 7 built of houses a river sand sea 2d. ing bul arms, th hundred ond floe sent to

it is in fact a military museum. Here are deposited the relics of former times; revolutionary trophies, taken at Saratoga, Yorktown, and St. John, present themselves at the entrance, and remind the visitor of Washington, Lafayette, Gates, and other worthies of past days. At the end of the room may be seen a little mortar, with the marks of U. S. Philadelphia, 1793, an intimate friend of 'old Mad Anthony' and a most destructive enemy to aboriginals. The total number of small arms falls not short of seventy-seven thousand. The other buildings are officers' quarters, barracks, armory, smithy carriage-shop, machine shop with an engine of twelve horse power, paint shops, lead and brass foundries, tin shop, accoutrement shop, and offices. The last named buildings are of brick, with shingle roofs. The yard, with its gravel paths and locust trees, is not unlike the garden of the Tuilleries in miniature. In the centre is a cistern or reservoir, intended, with the fire engine, to convey water to any part of the fabric.

3d. The front park presents in view the outside of the main arsenal, with the right and left wings of the commandant's and subalterns' quarters, and is chiefly designed as a grove, to add to the appearance of the 'tout ensemble.' This park is enclosed with iron railings, similar to those around or in front of the President's House, at Washington. After crossing the Butler road, it leads us, 4th, into the upper park, surrounded, likewise, with a permanent wall of stone. In its inclosure are the public stables, (of brick;) three small frame buildings, separated about eighty yards from each other, denominated as the composition, drawing, and preparation rooms, are seen from the road. About two hundred yards in the rear of these buildings is the magazine of powder, designed to contain (environs) one thousand three hundred barrels. The topographical scenery is not surpassed by any west of the Allegheny Mountains, and the climate is salubrious and fruitful.

LAND IN DUTCHESS COUNTY.—We are assured, by a friend, that within the past week, the sum of 100 dollars per acre, was offered for 400 acres of land at Fashill Hook—an evidence of the high value set on improved farms, in the neighborhood of this great city.

[From the Journal of the Franklin Institute.]

Report to the Board of Directors of Bridges, Public Roads, and Mines, upon the Use of Heated Air in the Iron Works of Scotland and England. By M. DUFRENOY, Engineer of Mines. Paris, 1834.

(Continued from Number 11.)

WORKS IN THE ENVIRONS OF GLASGOW.

The vicinity of Glasgow is one vast coal region, the first in Great Britain, both in the extent and the thickness of the veins. This coal basin is also very remarkable for the abundance of its iron ore, both imbedded in the argillaceous schist of the region, and in regular veins, often of considerable extent.

The layers of coal in the vicinity of Glasgow, which belong to the lower strata of the coal formation, alternate with beds of mountain limestone, so that in the same locality are often united the coal, the ore, and flux, and often the fire clay used in the construction of the furnaces.

These invaluable advantages are in part compensated by the enormous loss incident to the carbonization of the coal in this locality, as well as by the lightness of the coke produced. From these circumstances, a ton of iron requires at the Glasgow Works for its production, a much larger quantity of fuel than in any district of England.

The employment of the heated air has produced a revolution in the Scotch works, and enabled them to sustain a competition with those of Wales.

Clyde Iron Works were, as before stated, the first in which the heated air was tried. The apparatus now in use, (see figures 1 and 2,) is composed of a double row of horizontal pipes, a, a, a, 150 feet long. These pipes are nineteen inches in diameter, and one inch and a half thick. The exterior row passes behind the furnace, and enters the other row, dividing the air into two parts; so that the blast is carried equally to each tyeve.

The valves placed at E regulate the distribution of air, and stop either branch when repairs are required.

In the length of 150 feet, the tubes pass through five furnaces, or heaters, F, F, F, F, F, of which two are placed near the tuyeres; so that the air has no time to cool before entering the furnace. Figures 1 and 2 give an exact idea of the form and disposition of the five heating fires; they are connected by a conduit of brick, g, g, g, which envelopes the pipes; by this means the flame which escapes from the fireplace circulates about the pipes, and heats their whole length. To preserve the parts of the pipe immediately in contact with the flame, they are encased in fire brick the whole length of the furnace. In the first apparatus of this kind which was constructed, the ends of the pipes were inserted one in the other, having some play to prevent any rupture by expansion; the result was a great loss of air, and the plan was abandoned. Besides, it was remarked that a great waste always took place at the joints of the pipes; so that it was not sufficient to fasten them with bolts and

nuts; the joints were therefore covered with a ring of iron cast on after they were finished. By means of this precaution, the pipes lasted a long time; at the time of my visit, they had been five months in use without repairs.

On the exit pipes are small holes, V, V, by means of which any change of temperature in the air might be ascertained. This precaution is indispensable, because one of the essential conditions in the use of heated air, is, that its temperature be kept uniform—with this apparatus they raised the air to 612° Fahrenheit, which is higher than the melting point of lead.

In the Clyde Works, two of the four furnaces have each an apparatus like the one described, but in the other two there was no room for the extent of pipes, and they are contracted into smaller space, by being doubled upon themselves.

The working of a furnace with heated air requires no particular precaution; the operation is the same as before its introduction, the only difference consisting in the substitution of raw coal for coke. This substitution did not immediately follow the adoption of the new plan; it was some time after, and only when the temperature of the air was raised above the melting point of lead, that the immense benefit of the change

was discovered, giving a consequent diminution in the expense of manufacture.

The general idea adopted in Scotland, is, that certain qualities of coal cannot be employed crude, except when the air is highly heated. We have already said that at the Monkland Works, where the air is heated to 460° and 490° Fahr., coke is still used.

The descent of the furnace is very regular—the distances between the charges are nearly equal, the charging being regulated by the space left empty in the throat. The richness of the ore not roasted, varies from 22 to 34 per cent., and the composition of the charges follows this variation. At the time of my visit, the average yield of ore, after roasting, was 44 per cent., and the charges thus composed:

860 lbs. coal,  
520 lbs. ore roasted,  
100 lbs. lime.

They usually made 40 charges in 24 hours. During the two days that I witnessed the working of the Clyde Works, the number of the charges were,

July 4—from 6, A. M., to 6, P. M., 38  
from 6, P. M., to 6, A. M., 39  
“ 6—from 6, A. M., to 6, P. M., 37  
from 6, P. M., to 6, A. M., 40

The yield of the furnace in these four

castings, was, 4 t. 8 cwt.; 4 t. 9 cwt.; 1 t. 6 cwt.; 4 t. 12 cwt. Total, 17 t. 16 cwt. for 154 charges; or, 8 t. 17 cwt. 2 lbs. each 24 hours.

This result shows that a ton of iron is produced at an expense of 2 t. 8 cwt. 2 lbs. coal. The consumption of the heating fire is 8 cwt. Total, 2 t. 16 cwt. 2 lbs. per ton of iron.

The castings are made every twelve hours. The metal obtained is usually a mixture of No. 1 and No. 2. That which goes first from the hearth is No. 1. These two varieties of iron are distinguished by the small channels which furrow the surface of the metal while cooling.

The tuyeres are hermetically closed round with clay, and as they cannot resist the elevated temperature to which they are submitted, water tuyeres have been substituted similar to those used in the fineries. The figure 3 represents the tuyeres employed at the Clyde Works; they are of cast iron, and last various lengths of time, averaging five or six months.

The tuyeres are closed in, to prevent the entrance of cold air through the openings. There is no objection to this arrangement, because the air is so hot that no scoria accumulates upon the pipe, and the workmen are never obliged to free the tuyeres. There is a high white heat in this part of the furnace; nevertheless there are scarcely any sparks produced by the oxidation of the iron, and the particles that fall are black in the centre, showing that the metal is still covered with a small layer of melted scoria.

The flame issuing from the furnace is of a bright red, while that from the coke furnace, worked with cold air, is of a yellowish color. This difference of color is as marked as that which exists between the flame of alcohol colored by strontia and by baryta.

The pressure of the blast in the air vessel is two pounds and a half, or five inches of mercury to the square inch. It is the same near the tuyeres, only the gauge which indicates it is subject to great oscillations. This pressure was formerly three pounds. The opening of the tuyere is three inches; it was two inches and a half when cold air was used. The quantity of air forced into the furnace is less. The blowing engine, of seventy horse power, served only three furnaces; now it feeds four with ease. From the dimensions of the blowing cylinder\* the quantity of wind, which was 2827 cubic feet per minute of cold air, is now but 2120 cubic feet.

The furnaces of the Clyde have not been altered since the introduction of hot air. They had been in blast a long time when this new plan was adopted; one of them has been seven years in blast, and the regularity of its operations gives an earnest that it will last a long time.

At the commencement of this report, I

\* The steam engine which works the blowing apparatus, requires for fuel twenty tons of broken coal, or slack, per day of twenty-four hours, which costs one shilling and eight pence sterling per ton, (forty cents.)

have already stated the economy of fuel, and of flux, which had been obtained at the Clyde Works, by the introduction of hot air. I think it, nevertheless, useful to show the correctness of the estimate by transcribing a statement of the differ-

ent expenses of manufacture during a month while cold air was used, and a corresponding month, with the use of hot air. I make this statement from the books of the Works, to which I have been allowed access with a rare liberality.

**Consumption and Produce of three Furnaces, using Cold Air and Coke, during the month of February, 1829.**

	Coke.	Ore.	Flux.	Pig Iron.			Castings.	Total.
				No. 1.	No. 2.	No. 3.		
1st week	386	227 9	68 2	72 13	32 13	18 13	1 13	125 12
2d do.	411 10	242 11	72 11	51 19	37 11	47 2	6	136 19
3d do.	401	231 16	70 18	44 16	48 2	36 7	3	131 8
4th do.	301 10	177 13	53 6	53	27 9	26 3	0	105 12
	1500	879 9	264 17	222 8	145 15	130 5	2 2	499 11

Add the consumption of the engine, averaging one ton of slack to the ton of iron made.

**Consumption and Produce of four Furnaces, using Hot Air and Coal, during the month of February, 1833.**

	Crude Coal.	Ore.	Flux.	Pig Iron.			Castings.	Total.
				No. 1.	No. 2.	No. 3.		
1st week	516 15	490 7	91 16	81 4	38 15	155 3	"	265 2
2d do.	514	491 6	91 7	48 8	46 15	161 18	"	257 1
3d do.	521 15	486 8	91 8	94 12	59 10	109 8	"	264
4th do.	470 10	434 12	81 18	75 2	47 10	102 1	"	224 3
	2023	1902 13	356 9	299 6	182 10	528 10		1010 6

The consumption of the steam engine averaged eleven cwt. per ton of iron produced.

The result of an examination of these tables is, that, for one ton of iron produced, there was consumed as follows:—

1829. With Cold Air and Coke.			1833. Air heated to 612° Fahr. and Crude Coal.		
1. Coal for fusion—		t. cwt.	Crude coal,		t. cwt.
3 tons of coke, corresponding to coal,	6	15	Do. for steam engine,	11	
Do. for steam engine,	1		Do. for heating the air,	8	
	7	15		2	19
2. Ore roasted, 3523 lbs., or	1	15	Ore, 3780 lbs., or	1	18
Its average yield being 57 per cent.			Its average yield being 56 per cent.		
3. Flux, 1056 lbs., or	10		Flux, 704 lbs., or	7	
Daily production of furnace, 11,904 lbs., or about 6 tons.			Daily production of furnace, 18,025 lbs., or about 9 tons.		

The daily production having been raised at the Clyde Works from six to nine tons, the introduction of hot air has produced an economy in the consumption of fuel, and in the expense of manual labor.

The following shows the cost of manufacturing pig iron during these two periods:

	In 1829.		In 1833.	
	Cold Air.		Hot Air.	
Coal for melting, at 5s. per ton, (£1 20.)	6 13	8 98	2	2 40
Do. for the blowing machine, at 1s. 8d. per ton, (40 cents.)	2	80	11	22
Do. for the heating apparatus,			8	48
Mineral roasted, at 12s. per ton, (£2 88.)	1 15	5 04	1 18	5 47
Flux, at 9s. per ton, (£2 16.)	10	1 08	7	76
Labor, at 10s. per ton, (£2 40.)		2 40		1 60
General expense, interest of capital, 6s., (£1 48.)		1 44		96
Total,		19 74		11 89

Note.—The cost in sterling money is reduced to United States currency, at the rate of four dollars and eighty cents per pound.—[TRANS.]

(To be continued.)

**WEARING SPECTACLES.**—Mr. Curtis, the celebrated oculist, in a recent publication, is very earnest in teaching the

world, that when an individual feels obliged to wear glasses, for the first time, it is immensely important to future vision not to have the spectacle eyes too small. says Mr. Curtis, the glasses are not sufficiently large to cover the circle of the orbit, the wearer is obliged to look against the frame, as well as above and below it. The large, old fashioned spectacles, are therefore altogether superior to the modern article: oval bows he condemns in toto, as they exert a destructive influence over the organ, by obliging the whole muscular power of the eye to be exerted, in order to receive impressions through the very contracted window of the bow. He thinks highly of gauze spectacles, as screens to keep out the dust, so terribly destructive to vision in sandy regions and in cities, where the dust is whirled with tremendous violence through the streets, like blowing through so many tubes. He seems to be much opposed to operations on this delicately constructed organ.—[Ibid.]

Henry L. Ellsworth, of Connecticut, has been appointed, by the President, Superintendent of the Patent Office. Mr. E. accepts the office, and has proceeded to Connecticut to remove his family to Washington.—[National Intelligencer.]

**Facts from Williams' Annual Register.**—There are in the State of New York 56 counties, 781 towns and 9 cities. There are 116 incorporated villages in the State. The incorporated villages are governed by a President and Trustees, generally five in number, who are elected annually by the people. A State census is to be taken this year.—The total number of Post Offices in the State is 1,703. There are 260 newspapers printed in this State, besides several magazines. Papers are published in all the organized counties of the State except Franklin and Putnam. There are 25 daily papers, 15 printed in the city of New York, 3 in Albany, 3 in Troy, 2 in Buffalo, 1 in Brooklyn and 1 in Rochester. In the city of New York there are 65 papers published exclusive of magazines.—15 daily, 11 semi-weekly, 31 weekly, 3 semi-monthly, and 5 monthly. The average circulation of the ten large daily papers is about 1,700, or 17,000 total number of sheets issued daily. The total value of woollens manufactured yearly in this State, exclusive of those made in families, is \$2,500,000. The total value of all manufactures of iron in the State, is estimated at about \$4,000,000.

**Summary of Canals completed.**

	761	1,920

The assessed valuation of personal and real estate in the several counties in the state of New York for the year 1834, is \$459,673,135. The amount of auction duties for 1834 is \$193,470 19. The amount of tolls received from the state canals during 1834 is \$1,339,799.56. There are 90 banks in the state, with a capital of \$34,781,460. There are 14 marine insurance companies in the city of New York with a capital of \$4,550,000, and 29 fire insurance companies, with a capital of \$10,450,000. There are 27 insurance companies in the state exclusive of those in the city of New York, with a capital of \$4,501,731. In the state there are five colleges—Columbia College, and the University in the city of New York, Union College in Schenectady, Hamilton College in Oneida, and Geneva College at Geneva, Ontario county.—There are six theological seminaries, one in New York, one at Auburn, Cayuga county, one in Madison county, one at Hartwick, Otsego county, and one at Cazenovia, Madison county. The arrivals at the port of New York from foreign countries during 1834, were 1,932. During the same year 48,110 passengers arrived at this port from foreign countries. There are 41 whale ships owned in this state, employing a capital of over \$1,000,000, and crews of about 1,000 men.

The number of Attorneys and Counsellors at Law in the state of New York, in 1835, 9052.

The number of Physicians in the state is 2650.

The rank and file of the Militia of this state comprises 186,212 men, viz: horse artillery, 1271; cavalry, 7225 artillery, 11,396; infantry, light infantry, and riflemen, 163,301; fifty companies of artillery attached to infantry permanently, for inspection, 3019.

## NEW-YORK AMERICAN.

MAY 12-23, 1836.

## LITERARY NOTICES.

THE NEW-YORK ANNUAL REGISTER for 1835, by EDWIN WILLIAMS, New-York. This is the sixth year of this useful, improving and annually enlarging publication—and it has now so completely established its character for extent, variety, and accuracy, of information, as to render superfluous any thing beyond the mention that another volume has appeared, and that it is in every respect equal, and in point of paper and typography, superior, to its predecessors.

THE STRANGER IN AMERICA, or letters to a gentleman in Germany, by FRANCIS LIEBER: 1 vol. 8vo., Phil., CARST, LEA & BLANCHARD, for sale in New-York by WILEY & LONG. We recently took occasion to copy, from an English Review, a notice of this work of Dr. Lieber, and to express our concurrence in the praise there bestowed upon it. We are a queer people—we Americans; we will not buy books about our own country, unless they abuse and caricature us,—nor interest ourselves in the reputation of naturalized citizens—except, indeed, about election time. This book of Dr. Lieber, seems to us an illustration of both those remarks. It is certainly clever, agreeable, full of sparkling disquisitions, in which there is always a staple of thought and knowledge, and which, complimentary to Americans and American institutions. The writer has taken up his abode among us for good and for evil—he is one of us—and by his labors on that truly national work the *Encyclopedia Americana*, has done not a little to illustrate American literature. Yet these letters to Germany, originally published, under the title, we believe, of letters written during a tour to Niagara, are coldly received; and the praises of which they have been the object in English reviews, are not transplanted, as in the case of every word of eulogy on our native writers, is so eagerly done—into the newspapers of this country. We can assure our readers, nevertheless, they will find that "The Stranger in America" is a very agreeable and well informed companion.

HINTS FOR THE IMPROVEMENT OF EARLY EDUCATION AND NURSERY DISCIPLINE; from the 12th London edition, with additions. 1 vol. 12mo.—New York—WILEY & LONG.—The dedication of this work—brief, comprehensive, and speaking—opens its way favorably. It is in these simple but touching words—"Dedicated to Mothers by a Mother;" and well does it redeem the promise of such a dedication, for it is manifestly throughout, the production of a careful, firm, and affectionate mother, who loves her offspring too sincerely, to indulge in the selfishness which so often interferes with proper discipline, and who reverences too much the purity of childhood, to be, in any wise, a party to impairing it, by undue indulgence. Let the following extract show her principles:

Success in Education depends,

First—More on Prevention than Cure; more on securing our children from injury, than on forcing right. If we wish, for instance, piousness, we shall effect it, not by compelling them to feats of guarding him from all impressions witnessing a weak and cowardly

Example rather than on Precept be bodies of children are imprinted by the air they breathe, so are the moral atmosphere which surrounds them, the tone of character and general influences of those with whom they live.

Secondly—On forming Habits rather than on instilling Rules.—It is little to tell a child what to

do; we must show him how to do it, and see that it is done. It is nothing to enact laws, if we do not take care that they are put into practice, and adopted as habits. This is the chief business of education, and the most neglected; for it is more easy to command, than to teach and enforce. For example; a child will never know how to write by a set of rules, however complete; the pen must be put into his hand, and the power acquired by repeated efforts, and continued practice.

FOURTHLY—On regulating our Conduct, with reference to the Formation of the Character when matured, rather than by confining our Views to the immediate effect of our labor.—Premature acquisitions, premature quickness of mind, premature feeling, and even premature propriety of conduct, are not often the evidences of real strength of character, and are rarely followed by corresponding fruits in future life.

LASTLY—On bearing in mind a just sense of the Comparative Importance of the objects at which we aim.—As in the general conduct of life, it is the part of wisdom to sacrifice the less to the greater good, so in this eminently the case in the subject before us. Now the primary, the essential object of education is this—to form in children a religious habit of mind, founded on the divine principles of Christianity, and leading to the habitual exercise of practical virtue. To this, all other attainments are wholly subordinate.

THIRTY YEARS CORRESPONDENCE BETWEEN BISHOP JEBB AND ALEX. KNOL. 3 vols. 8vo. Edited by the Rev. CHARLES FORSTER, formerly domestic chaplain to Bishop Jebb. Philadelphia. CARST, LEA & BLANCHARD. For sale in N. York by WILEY & LONG.—A correspondence through the space of nearly the third of a century, between two men of warm attachment to each other—in the most unreserved confidence—and discussing matters of taste, literature, but mainly religion, with open hearts and minds, could not fail—even if the writers were only men of ordinary capacity—to be a record of deep interest and attraction. But here the parties are profound scholars—admirable writers—discriminating critics: add, to this, the charm of feeling that what you read in these letters, is the honest outpouring of one tried friend to another—not written for effect—not dreaming of future publication, as Lord Byron, in all his letters to Murray and others, so manifestly was—but written as the friends would have talked, if together, in the fullness of their understanding and their hearts.

The general and most frequent topics of the letters is, of course—religion—and the various duties enjoined upon Mr. Jebb by his different stations in the church, first as Curate, at 50l. a year, till he rose to the Bishopric of Limerick. There is, moreover, a great deal that all readers of taste will be interested in—so, at least, we feel quite authorized in pronouncing, from the casual and interrupted perusal we have been able to give to these volumes.

THE INTIFER OR THE FALL OF MEXICO: A ROMANCE, BY THE AUTHOR OF CALATHA, 3 vols. PHILADELPHIA, CARST, LEA & BLANCHARD. We have read these volumes through with unflinching interest; they evince power of a high order, and thorough preparation for the work undertaken. They embody the very spirit of the times in which the story is laid, and reproduce the days and the scenes, as though they were living before our eyes. The style of the work is indeed as striking as the scenes it depicts, and is a superb display of unobtrusive and delicate, arising however from a richly stored mind.

The story is that of the fall of the island empire of the city of Mexico, after the long and bloody operations against it conducted by Cortez in person, and the gallant, protracted, but eventually triumphant defence of the youthful and intrepid Montezuma. The hero of the story, however, is Juan Loma; the heroine a very remarkable creation, La Montezuma; and not least, the noble dog

Beo—a type not overdrawn, of the incorruptible fidelity, and courageous affection, of that trust of the friends of man—among the true creation—and hardly limited to that.

THE AMERICAN MONTHLY, for May: New-York, D. K. MINOR.

THE KNITTERS-ROCK for May: New-York, WILEY & LONG.

THE TOWN REGISTER, for May: Baltimore, L. BATHURST.

We have only had time to skim over the pages of the Monthlies,—but found wherewithal to be well pleased. There is in the American Monthly, both variety and ability.

NATIONAL ACADEMY OF DESIGN; 10th Annual Exhibition.—We conclude our Review to-day, with a notice of a portion of the pictures in this exhibition, which, as a whole, is creditable, though we are by no means a convert to the opinion expressed by some knowing members of Congress, in the debate respecting the vacant panels in the Capitol, that in this country painters in all the highest departments, are plenty as blackberries.

## SUMMARY.

The annexed Acts are of general interest:

An Act relating to the privileges of Firemen of the respective cities within this State, passed May 8th, 1835.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

§ 1. The firemen of the different cities within this State, in case of removal from one city to another, shall be allowed the time which they may have served as such firemen in the city they left, in the city to which they transferred, upon producing a certificate of such service, signed by the chief engineer of the city so left, and being reappointed a fireman in the city to which they have removed.

§ 2. When every such fireman shall have served as such for so long a time thereafter as shall make the whole term of service the same as required by the law of Firemen residing in Albany, removed to, they shall be entitled to all the privileges and exemptions now secured by law to the firemen of the cities of Albany and New York.

An act in relation to the assessment of highway labor. Passed April 24, 1835.

The people of the State of New York, represented in Senate and Assembly, do enact as follows:

§ 1. The real property of non-resident owners, improved or occupied by a servant or agent, shall be subject to assessment of highway labor, and at the same rate as the real property of resident owners.

§ 2. The twenty-second section of title first, chap. 19th, part first, article second of the Revised Statutes, shall be amended so as to read as follows:

§ 22. The commissioners of highways in each town, at their first or any subsequent meeting, shall make out a list and statement of the contents of all lots, pieces or parcels of land within such town, owned by non-residents therein; every lot so designated shall be described in the same manner as is required from assessors, and its value shall be set down opposite to such description; such value shall be the same as was affixed to such lot in the last assessment roll of the town; and if such lot was not separately valued in such roll, then in proportion to the valuation which shall have been affixed to the whole tract of which such lot shall be a part.

§ 3. The twenty-fourth section of the same chapter shall be amended so as to read as follows:—

§ 24. In assessing such estates and assessing the same, the commissioners shall proceed as follows:—

1. The whole number of days' work to be assessed in each year shall be ascertained, and shall be at least three times the number of taxable inhabitants in such town;
2. Every male inhabitant being above the age of twenty-one years, (excepting ministers of the gospel) and the heads of every domesticity, paupers, and idiots and lunatics, shall be assessed at least one day.
3. The residue of such days' work shall be apportioned upon the estate, real and personal, of

every inhabitant of such town, as the same shall appear by the last assessment roll of the said town; and upon each tract or parcel of land, of which the owners are non-residents, contained in the list made as aforesaid.

4. If, after such appointment, there shall be any deficiency in the number of days' work determined by the commissioners to be performed in their town, the then ensuing year, such deficiency shall be assessed upon the estates, real and personal, of the inhabitants of the town, and upon each tract or parcel of land of which the owners are non-residents, according to the last assessment roll.

5. The commissioners shall affix to the name of each person named in the list furnished by the overseers, and also to the description of each tract or parcel of land contained in the list prepared by them of non-resident lands, the number of days which such person or tract shall be assessed for highway labor, as herein directed, and the commissioners shall subscribe such lists and file them with the town clerk."

**THE MICHIGAN WAR SUSPENDED.**—The Buffalo Commercial Advertiser of the evening of the 11th, has this paragraph:

Messrs. Rush and Howard, who have been acting as Mediators between Ohio and Michigan, left this city yesterday, on their return to Washington. We learn from them the important fact, that Gov. Lucas with his suite, and the militia who were assembled at Perryburgh, have returned to their respective homes.

The Commissioners for running the northern boundary line of Ohio, have also returned, and will suspend their operations until after the meeting of the Ohio Legislature in June, a special session of which, at that time, has been called by Governor Lucas.

We are much gratified to have it in our power thus to assure our readers, from an official source, that no further difficulties need be apprehended between the two Great Powers—in Cabinet parlance—for some months, at least.

[From the Baltimore Patriot.]

**BALTIMORE PROSPECTS.**—We mentioned, a few days since, a purchase of a large square of ground in the eastern section of the city, by speculators from abroad. We have now to notice the purchase of the country residence of the late Mr. Didier, within the western limits of the city, about 19 acres, for \$24,000, by a citizen of New York, who has bought, also, a square of ground between German and Pratt streets. It is believed he will more than double his money within a short period. Capitalists can no where make more profitable investments than in Baltimore, at the present time. The city is destined to "go ahead" steadily and rapidly.

**STEAMBOAT EXPLOSIONS.**—The National Intelligencer, advertising to the frequency, and fatality, of these occurrences, says very justly:

"There is no certain remedy for these accidents but to make the owners of the boats sweat for them. A penalty of \$5,000 for the death, and \$1,000 for the damage of every individual, caused by the bursting of boilers, would soon put a stop to such occurrences, for they are all the result of negligence, incapacity, or culpable mismanagement."

**THE GRAIN AND FLOUR MARKET.**—The price of Grain and Flour as a more general concern than that of any other articles of merchandise,—for we all eat bread—naturally attracts attention—just now. It is, we observe, said in some of the Southern papers, that the rise here in these articles, is probably speculative, and partaking of the gambling spirit, which the rise in Stocks and Real Estate, is supposed to exhibit.

According to letters however, we have seen to-day, from the grain growing region of this State, we apprehend there is really too good ground for the rise, in the shortness of the supply left over from last year, and in the injury which the severe winter has done to the wheat in the ground. At any rate, \$1 25 was refused at Genesee, last week, (on the 9th,) for wheat.

Fodder for cattle is also fearfully scarce. Many head have perished, and at Rochester hay has been

sold at \$30 per ton. Even at the Genesee Flats it commands \$14—and in many places, farmers are doling out with a scanty hand to their cattle, the wheat which was reserved for their own use.

The New York spirit of speculation seems to find itself too much circumscribed within the narrow limits of this city and its vicinity, and is extending itself, as will be seen by the annexed paragraph, to Albany, and even to Baltimore.

[From the Albany Argus.]

**REAL ESTATE SALES IN THE CITY OF ALBANY.**—The recent sales of real estate in this city, although extending in the aggregate to a large amount, are by no means in advance of the actual value of property.

The sale of the extensive and valuable estate of Mr. E. C. Delevan, for some \$250,000, is a purchase that promises to return, ultimately, if not immediately, a large profit to the company into whose hands it has fallen. During the past and previous year, real property in this city has not advanced in value with the progress of population and the upward tendency of rents. It may be said to have been stationary. It could not be doubted, however, that the increasing business of the city, the multiplied travel and intercourse, and particularly the prospect of the removal of the obstructions to the navigation, would give an impetus to real property. It was obvious that it would start forward as soon as these combined causes should become in any degree operative. And such has been the case. The purchase of this large estate was made just at the turning point, and will scarcely fail to prove advantageous to the new owners and to the city. The south lots alone must be soon worth the entire purchase money.

The purchase of the property of Jas. Stevenson, Esq., for \$42,000 was also judiciously made. It is in the heart of the city, and among the most valuable real estate on State street. We suspect that more than one of our citizens would be glad to take the property at the price paid by the New York purchasers.

Other sales of lots and property in the city indicate a decidedly upward tendency in value and demand.

**GREAT SALE OF REAL ESTATE.**—The Country Seat of Com. Chauncey near Hellgate, which was sold by the Commodore a few months ago for fifty thousand dollars, was re-sold in city lots yesterday, for nearly one hundred and twenty thousand dollars.

It is distant about five miles from the City Hall, and contains about 15 acres, we believe.

**STEAMBOAT CASE—A POINT TO BE MOOTED.**—

It is stated in the Richmond Whig, that the steamboat *Columbian*, plying between Baltimore and Norfolk, on a recent occasion, meeting on her way up, off the mouth of the James River, a new boat, the *Thos. Jefferson*, built to run between Richmond and Norfolk, refused to receive on board—as was usual, and as had been done we presume hundreds of times, from other boats belonging to the same parties as the *Columbian*—passengers bound to Baltimore. The objection was not want of room, nor stress of weather, which prevented the boats coming to, with safety—for the passengers from the *Thos. Jefferson* were alongside the *Columbian*—but that they were from a rival boat. They were accordingly driven back.

Now the point we desire to moot is, whether—in virtue of advertisements, or common usage, the *Columbian* was known, and relied upon, to take passengers from the Richmond boats when meeting between Norfolk and the mouth of the James River—there would not lie an action against the proprietors, or master, for breach of contract, in the case referred to by the Whig?

They who undertake for hire, to run public conveyances, whether on land or water, do contract engagements towards the public, from which they should not be, and we presume are not, at liberty, from any capricious, or selfish, or spiteful motives, to exonerate themselves, without due notice. While

they are common carriers of goods or passengers, they must abide by their own undertaking, or be subject to penalty for not doing so. This, at least, is the common sense view of the case, and therefore possibly the common law—though between common sense and law there be, sometimes, sad discrepancies.

**Pennsylvania Loan.**—The loan of \$959,000, authorized by an act of the last session of the Legislature, and for which proposals were received at the Office of the Secretary of the Commonwealth until the 9th inst., was taken by Elihu Chauncey, Esq., for the Bank of Pennsylvania, at one hundred and twelve dollars and two cents for every one hundred dollars of stock. We understand that the Messrs. Phillips bid \$111 74.—[U. S. Gazette.]

[From the Globe of Yesterday]

The following gentlemen have been invited by the Secretary of War to attend the next General Annual Examination of the Cadets of the Military Academy, which will commence on the first Monday in June:

**Maine.**—Hon. M. Mason.  
**New Hampshire.**—Col. S. Collins.  
**Massachusetts.**—\*Hon. N. Bowditch.  
**Connecticut.**—Rev. J. Cogswell, \*Rev. H. Crosswell.  
**New York.**—Hon. B. Green, Hon. C. C. Ferris, Gen. Geo. R. Davis, \*George W. Clinton, Esq., John Hunter, Esq.  
**Pennsylvania.**—Dr. C. D. Meigs, Gen. W. S. Rogers, Wm. Robinson, Jr., Esq., Wm. J. Leiper, Esq., Wm. C. Frazer, Esq., \*Hon. Geo. M. Dallas, Hon. Calvin Blythe.  
**Virginia.**—Dr. E. H. Carnicheal, Col. John Heth, Hon. P. V. Daniel.  
**North Carolina.**—John Bragg, Esq.  
**South Carolina.**—Dr. E. S. Davis.  
**Georgia.**—Col. Wm. C. Lyman.  
**Kentucky.**—Thomas J. Pew, Esq.  
**Tennessee.**—Right Rev. J. H. Otey, Bishop of Tennessee.  
**Indiana.**—\*Dr. E. Newland.  
**Alabama.**—Col. Peter Martin.  
**Army.**—Brig. Gen. Henry Atkinson.

\*Those gentlemen who have this mark before their names have declined.

[Hudson's News Room Correspondence.]

**STEAM BOAT DISASTER.**—The Steamboat William Parsons, on her passage from New Orleans to Little Rock, was snagged and sunk, in Arkansas river, about 40 miles above port Arkansas. She had a cargo worth about \$60,000, fully insured; part of it has been saved in a damaged state. No insurance on the boat, which, it is supposed will be lost.

The Brig Maese, hence for Sisal, is ashore at Barnegat, and will probably be lost.

[From the Nat. Gazette.]

The annexed article is "going the rounds" of the newspapers.

"An English paper speaking of honor, the soreness of which, it says, is betrayed by the sensitiveness, makes this just remark: 'The common sense of mankind instructs them that a sound robust honor is never touchy; it is when it becomes weak and tender that it goes about querulously asking this man and that man whether they intended to hurt or offend it.'"

Neither the common sense nor common experience of mankind warrants this theory, supposing touchy to mean sensitive. The most pure and delicate—those who have labored most earnestly to deserve the best reputation—are apt to be "tremulously alive" to every kind of obloquy or injurious suspicion. Honor may be thoroughly sound and incorruptible, but not robust so as to be unaffected by opinion. Falsehood alone can annoy it, and does severely in the plurality of cases. There are, indeed, public pursuits and situations, so particularly and constantly able to obloquy, that the natural susceptibility of true honor is gradually lessened; yet, eminent men of the noblest virtue, public and private, have even perished, in advanced stages, from tenderness or irritability with regard to their fame. Few are content or able to live down merely the judgments of ignorance and the inventions of malice. Querulousness, indeed, is never manly; and rarely serviceable; but sensitive

ness is common where firm, conscious honor and high moral courage are united. On this account slander is doubly mischievous and detestable.

**THE HONORED CHIEF JUSTICE.**—The National Intelligencer of yesterday, referring to the rumors of the ill-health of Chief Justice Marshall, has this cheering paragraph:

We are happy to say that a letter from the Chief Justice, upon business, was yesterday received at the office of the National Intelligencer, the contents and appearance of which indicate nothing like indisposition of either mind, or body, in the writer. The hand is as firm, and matter as germane to the purpose, as usual with him. Furthermore, the Richmond Compiler of Friday last states, that the Editor saw the Chief Justice on the previous day, taking his accustomed walk, half a mile distant from his residence.

The funeral ceremonies yesterday, in honor of the late General Leavenworth, were altogether creditable to the feelings of the city, and to the arrangements and precision of the military. The day was hot, but fine, and the crowd of spectators great.

The Journal of Commerce gives these particulars:

The Superior Court room was reserved for the Judges of the Law Courts, Members of Congress, and State Legislatures, Society of Cincinnati, &c. The Common Council room was reserved for the reception of the Common Council, Clergy, Pall bearers, Officers of the Army, Recorder, Ex-Mayors and Recorders, Ex-Aldermen and Assistants, and the Corporation of Brooklyn. The remains of the deceased lay in state in the Governor's room. On the plate of the Coffin, which was a very superb one, was engraved the words, "BRIGADIER GENERAL HENRY LEAVENWORTH, DIED, JULY 21ST, 1834, AGED 51 YEARS." About 4 o'clock the funeral procession left the City Hall, and proceeded to the Steamboat, amidst discharges of cannon. The following is a brief memoir of the deceased, for which we are indebted to the kindness of one of his relations.

General Leavenworth was born in the State of Vermont, and in the year 1806 came to the town of Delhi, in Delaware Co., N. Y., where he studied law under General Root, and continued practicing it until the year 1812, when he entered the army as a Captain, at the head of a volunteer corps which he raised himself, and from that period till his death he remained in the army. He commanded a battalion in the 9th regiment at the battles of Chippewa and Bridgewater. After the first of these battles, he was made Lieutenant Colonel, and after the second, where he particularly distinguished himself for his gallantry, he was made Colonel. At this battle most of the officers were wounded, and for a part of the day nearly the entire command devolved upon him. He was however at last wounded himself. Whilst he was holding out his arm pointing towards the enemy, a cannon ball struck his arm and knocked him off his horse. After the battle, he retired to Delhi, where he remained five or six months, and then rejoined the army. When peace took place, he was appointed to the command of Sackett's Harbor, and was subsequently stationed at Jefferson barracks, a little below St. Louis on the Mississippi, afterwards at the Falls of St. Anthony on the Mississippi, and other outposts, until the summer of 1834, when he marched in command of the dragoons, on an expedition to the settlements of the Pawnee and Comanche Indians. This was unfortunately his last campaign; he died on the 24th of July, 1834, of fever, at a place called Cross Timbers, on the False Washita. His remains were at first taken to Cantonment Jessup, and from thence to New Orleans, from which place they were shipped for this port about six weeks ago. Prior to the shipment the flesh was separated from the bones and nothing but the latter was brought here. They arrived a few days since, and were yesterday put on board a steamboat, to be conveyed to Delhi, where his wife, who died in 1811, lies interred.—She was the sister of Doctor Knapp of this city. In all his different relations in life he sustained the character of a brave, amiable, intelligent and highly honorable man.

**MISSIONARIES.**—The ship *Shepherdess*, which has sailed from Boston for India, has on board the

Rev. John M. S. Perry and lady, of Mendon Massachusetts, and Rev. J. J. Lawrence and lady, of Genesee, New York, destined for Ceylon; Rev. Henry Ballentine and lady, of Marion, Ohio, and Mr. E. A. Webster (Printer) and lady, from Utica, New York, destined to Bombay—all sent out by the American Board of Missions.

**BALTIMORE, May 13.**—*News.*—The Board for the examination of Midshipmen, consisting of Captains Ballard, Dallas, Bolton, Claxton, and Kearney, convened yesterday, in this city. Between forty and fifty Midshipmen have reported themselves, prepared for the ordeal, and, with good wishes for their success, we bid a "pleasant passage."—[Patriot.]

**The Astor Hotel, N. York.**—The Boston Atlas says, that this House has been taken by the Messrs. Boyden, of the Tremont House, Boston.

**Shocking Accident.**—We learn that as the Northern Stage was passing over Culpepper's Bridge, between Halifax and Louisburg, on Saturday last, on its route to this city, the feet of one of the horses got caught in a hole, which so alarmed the others that they started to run and upset the Coach. Several of the passengers were seriously injured. One had his back broken, and, it is said, cannot possibly survive; the driver also, we are informed, was in a dying state. Two or three of the horses were either killed or drowned. These are all the particulars we have been able to glean.—[Raleigh Reg., 18th May.]

Capt. Douglas, (of brig *Elma*, from Guayama, P. R.) was informed by the Am. Consul, and his merchants at Guayama, that there was a report that 14 plantations at Santa Croix had been destroyed by fire.

In a short time will be published, by Messrs. Carey, Lea & Blanchard, "The Conquest of Florida, by Hernando Soto," a work in two volumes, derived from original and authentic chronicles, by Theodore Irving, Esq. the nephew of Washington Irving.—We congratulate the author upon the success of this his first attempt to follow in the footsteps of his distinguished uncle. It furnishes conclusive evidence that he will do no discredit to his name, and that we may expect much from his devotion to literary pursuits. The subject is one of considerable interest both from its historical importance, and its romantic character, and is treated in a way that cannot fail to engage the attention of every reader. The dedication to the author's uncle, does equal honor to his head and heart.—[Nat. Gazette.]

**Navigator Islands.**—This group lies in about 13 south latitude, and 171 West longitude. Captain Worth, of the *Howard*, informs us, that having visited most of the islands in the South Pacific, he considers the Island of Oteewhy as presenting advantages and facilities to whalers, superior to those of any other island in that Ocean. It affords fruit, yams, poultry, swine, &c. in the greatest abundance; plenty of wood, and excellent water. For a musket the natives give 13 hogs, or 800 to 1000 yams; and great quantities of fowls, coconuts, bananas &c. may be purchased for a few pipes, flints, and blue glass beads. The fruit is generally obtained at the N. W. part of the island; but hogs, wood and water are procured from the north side.—Sufficient supplies may be taken on board in the short space of four days; and no danger need be apprehended from the natives, provided the precaution be taken to keep the head chief on board as a hostage, day and night—a requisition very willingly complied with when two or three of the natives, and an interpreter, are also allowed to remain. By pursuing this course in both of his visits to this place, Capt. W. passed and repassed unarmed in his boats with perfect safety, and found the natives extremely civil, never attempting to steal from the boats on shore, nor while on board his ship. He thinks however, that without this precaution, they would not hesitate to seize a boat and crew, merely for the sake of two or three muskets—which article they seem very anxious to obtain, though they never inquired for shot or ball. The white residents (of whom there are only two, who are chiefly engaged in agriculture) informed Capt. W. that they made no other use of the muskets than to discharge them at their great feasts—considering those the best which made the loud-est reports!—[Nantucket Enquirer.]

**Bonin Islands.**—These Islands are about midway between the Ladrões, and the coast of Japan—say lat 27 N., lon. 143 E.—Plentiful supplies of yams, potatoes, corn, hogs, water and wood—together with fine green turtle, weighing from 400 to 600 pounds each, may here be procured. The ship *Howard*, during her recent voyage, cruised several weeks in the vicinity, between the 25th April and 8th June last, and obtained considerable oil, though the weather was unfavorable most of the time. Great numbers of whales were seen during this period. The H. took on board 40 bbls yams, and 30 do potatoes—also, from the South Island, 38 large turtle. There are at the North Island, on the western side, some thirty inhabitants consisting of five industrious white men, and 90 to 25 men and women from the Sandwich Isle.—These settled there in 1828, and have cleared about 1000 acres of land—the soil of excellent quality—though in the months of April and May their plantations suffer much from the heavy rains. At the date above mentioned, they had on hand about 1000 bbls yams and as many bushels of good corn, ready for disposal to such vessels as might call for recruits, and at prices similar to those of the Sandwich Islands.

This island (the North Island) affords one of the best harbors in that ocean. Supplies may be obtained by lying off and on; but near the shores of each island there are strong currents setting in various directions. A ship can stand into the south island, send her boats on shore, and in two hours they can return, each bringing five turtle, being as many as a boat can float with. For the prevention of scurvy, a fresh stock of vegetables of almost every kind, and abundance of the finest melons, may be obtained in the months of June and July—being a convenient time for the ships in that region, as the whaling seasons on the coast of Japan grows later every year.

Capt. Worth, from whom we derive the above details, is of opinion that an error exists in the location of these islands as laid down on most charts. From his observations, carefully and repeatedly taken, he judges them to be at least 30 miles South, and 70 miles East, of their places on the charts. On comparing his observations with those of several other shipmasters who were there at or about the same time, he came to the same result.—[Nantucket Enquirer.]

**THE WEST INDIA EXPERIMENT.**—The Gazette, of this morning, publishes a letter from the Island of Jamaica, of the 18th ult., which, after acknowledging the receipt of some newspapers from this city, gives this encouraging account of the conduct of the emancipated slaves in that island.

Observe some of them are very incorrect regarding the conduct of the negroes, and the aspect of the country in general; by those representations it would appear, that the Island was all in confusion—the estates and plantations all destroyed—horror and dismay staring us in the face, dreading butchery and bloodshed at every step—but I am happy to say, it is not only far, but altogether otherwise. We are all, God be praised, quite well and happy,—my negroes conducting themselves with every propriety and decorum, and I never had less trouble with, or more work done by, them."

**The Canton (Chinese) Register says—**

"Of all the frontier parts of the Chinese empire, the coast is, perhaps, in the most defenceless state. An inefficient navy with dismantled forts can afford little protection. From the Choo-keang (Pearl river) of Canton to the frontiers of Manchoooria there are numerous navigable rivers which lead to the most flourishing cities of the empire; spacious harbors to contain whole fleets, and water communication by means of canals to the most distant parts of the empire. They cannot be ignorant that six provinces are assailable, and that the most important parts of the empire lie open to the grasp of a superior maritime power. If the government officers therefore tremble at the sole thought of irritating a foreign power, which has the means of punishing their arrogance, we must not consider their fear unfounded. They may have recourse to haughty edicts and a show of power; but when all stratagems and expedients are exhausted, they will sue for peace as humbly from, as they formerly, in the height of pride, announced their decrees to, the barbarians."

[From the N. Y. American.]

**ARTIFICIAL MARBLE OR STONE COFFINS.**

WE some time since alluded to the fact of Parker's cement having been proposed to be applied to the making of coffins. We have since had an interview with Mr. White, one of the gentlemen who have obtained a patent for this novel species of manufacture. Mr. White has left a sample of the cement thus prepared, at our office, where the curious may call and see it. It is certainly another extraordinary evidence of the success and rapidity with which the inventive genius of our countrymen strikes out new paths and new discoveries in the arts, while the older nations of the earth are creeping behind us at the slow and crawling pace of the snail or sloth. The sample of cement in question is almost two thirds of an inch in thickness, solid and hard, yet light in its texture, and on the outside polished, and afterwards varnished of a dark walnut color.—This glazing or varnish, Mr. White informs us, may be made, as we suggested to him, in imitation of mahogany, maple, rose, or any other elegant wood. The coffins, it is presumed, are to be made with the lids separate. After the body is placed in it, a thickness of cement is to be laid on the edge of the coffin, to connect the lid, leaving a small opening, to be used temporarily until the air is exhausted by a receiver. This opening also being filled in, the whole is perfectly air and water-tight. The interior being deprived of air, decomposition of the body, and the breeding of those germs of insects which are supposed to be inherent in our flesh, cannot, of course, go on, and must be suspended. We know how deeply interesting this subject is to the feelings of the world, and how few there are so callous as not to wish to preserve unaltered, after death, "this sensible warm being," and still to gaze on its cold tenement as the silent but eloquent image of the spirit that once animated it, and which we know may be effected, by exclusion from air and moisture, from the opening of the leaden coffin of the unfortunate Charles I. during the time, and in the presence, of Geo. IV. Though two centuries had elapsed from his death, the very color of the complexion, and the pleasant smile of the features, were the same as in the best portrait of him taken at the time, from life, by the celebrated Vandyke. The Egyptians, deprived of convenient burial places by the inundations of the Nile, and admonished by their belief in transmigration, resorted to embalment. Catacombs and pyramids were built in honor of the dead, whom they respected more than the living.—The invention of which we speak far excels this complicated process, and we doubt not it will be entirely substituted for destructible wood, and come into general use, not only for coffins, but for the kinds of vessels and receptacles in which it is desirable to preserve the contents from dampness, from the external air—thus, for records, public documents, books transported to great distances, over the sea, &c. It is also proper to add that, in these air-tight coffins, Mr. White proposes to insert in the lid, over the face of the corpse, a thick plate of transparent glass, while the cement is soft, and which thus, on hardening, becomes a part of the lid. Thus, the friends and relatives of the deceased may here view, after death, at their discretion, the revered face itself on which they doted, in life, with a parent's devotion, a brother's affection, or a sister's love.—In fact, not only might the body be thus visited in its vault, but, so far as its freedom from taint is concerned, might be kept in the residence of the living. If buried, the grave need not be deeper than the surface.

Mr. White, and Doctors Hoyt and Dayton, of Syracuse, are owners of this improvement.

Mr. White is joint owner with Mr. Parker in the cisterns of this material, and some other improvements. Those going into either branch, would find their interest, therefore, in the opportunity of embracing the whole. Will not undertakers, as a matter of interest, be disposed to adopt the stone coffins at once, in preference to those of wood?

We take the above extract from the "Star"—embodying many of the considerations in favor of these coffins. We, however, shall speak further on this subject, and in relation to the immense value of this cement generally, as soon as our time will permit. One of the proprietors, Mr. White, (who can be found at Howard's Exchange, or at the Office of the American Cement Company, Broad

street, New York,) has exhibited to us a specimen of the coffin spoken of, which embraces all qualities of safety, duration and imperviousness to air and water—and is not, withal, much heavier than the heavier woods.

The material is one, which must, as it strikes us, come into very general use for cisterns, &c.

**EXQUISITE ART.**—It is generally urged as a reproach to the works of art, as contradistinguished from those of nature, that they cannot bear the scrutiny of microscopic examination. Mr. Charles Toppan, of the house of Draper, Toppan, Longacre & Co., of Philadelphia, has, however, produced a specimen of attenuated workmanship, that not only challenges this test, but is absolutely inaccessible to any other. With a degree of minuteness, scarcely conceivable by the uninitiated, and not easily rendered credible even to the artist, he has contrived to engrave, beautifully and distinctly, the whole of the Lord's Prayer and the Ten Commandments, in the area of a circle only three-eighths of an inch in diameter. In this version—which is precisely that of the Episcopal Church, except that he has accidentally added the word *done*, and repeated the word *him*—there are no less than fifteen hundred and nine letters and figures. The space occupied, is one-tenth of a square inch; and the whole Bible, printed in a character equally minute, would only cover a space of seventeen inches square. This may seem incredible; but as a square inch, by accurate calculation, will include fifteen thousand of Mr. Toppan's letters, 263 square inches will include all the letters in the Bible. The Lord's Prayer forms only one-fifth part of this little wonder, and occupies a space less than one-fifteenth the size of an average sixpenny piece—so that instead of one copy of this prayer within the compass of a sixpence, Mr. Toppan's graver would produce fifteen. I have seen the Prayer and Ten Commandments, copied from Mr. Toppan's version, covering a circle of five inches in diameter; it contained, as his does, thirty-eight lines, and was in a character quite as minute as it could be, and continue pleasantly legible by the naked eye, and yet each letter occupied as much space as one hundred and sixty-six of Mr. Toppan's. Can there be a greater security against counterfeits than the exquisite skill of such an artist? N. W.

We have seen the very extraordinary specimen of minute engraving above referred to—and certainly, nothing but the evidence of our own senses could have satisfied us, of its perfect distinctness, and beauty, of execution.—[Ed. N. Y. Am.]

**Mr. Whittemore's Cotton Gin.**—We had the opportunity this morning of inspecting Mr. Whittemore's Gin for Long Staple Cotton. Mr. W. after several attempts has at length brought his Gin to that state of improvement, that leaves nothing to be desired. The little space occupied by it, the ease and rapidity with which it is propelled, the economy of its cost, its little liability to injury, and the facility with which the wear and tear to which it is incident may be repaired, will render it a great acquisition to the Sea Island Planter.—[Charleston Patriot.]

**Niagara Hose Company, No. 2.**—We called yesterday afternoon, to view the new carriage of this company, which is well worthy of notice, being incomparably superior in point of splendor to any we have yet seen, and excelling by far in regard to taste and richness of embellishment, any hose carriage in the city. It was built at the Corporation yard, at a cost of nearly \$4000, including the hose, which is 800 feet in length, being longer by 600 feet than the hose of most of the other companies. The silver plating was done by John Boardman, 249 William street; the boxes were painted by John Quidor, 46 Canal street, who certainly deserves great credit for the performance, exhibiting as it does the hand of an accomplished artist;—the carving, painting, and bronzing, is the work of Messrs. Boeckel & Moriarty, 34 Canal street, and entitle these gentlemen to much praise, too;—the leader-jacket, is the work of Messrs. Wilson & Roberts, 131 Bowery—the carving by Watkins & Barry, Chatham-square. The cost of ornamenting was about \$1000; defrayed, of course, by the individuals composing this enterprising and spirited company.—[Mercantile Adv.]

This year has been more than usually fatal to the *Moore Deer*. The Loretto Indians have killed

about thirty this spring, and probably an equal number has been killed by other hunters. The deep falls of snow, and the prolonged frosts of the spring which form a crust on its surface, afford a very favorable condition of things for this description of deer hunting, which is probably peculiar to North America. The Moose has a loose hoof, not spreading like that of the Rein Deer, it consequently sinks to the ground at every footstep. In the fall, the brood choose their beat where the shoots of their favorite trees are most abundant, and treading the snow at each fall, they manage to pass the winter, if undisturbed. The parties who seek them, first find their beat, and if the crust and snow are favorable, they start the deer and pursue them on snow shoes. The exceedingly timid animal, first rushing off with a strong and bold full speed, soon flags, and a couple of miles, or rather more, according to the state of the snow, brings up his pursuers, to despatch him with a gun, or to cut the sinews of his hind legs with the tomahawk. Its senses of smelling and hearing are exceedingly acute, and it is almost impossible to surprise it, but it easily thus falls overpowered by its own struggles, claiming the pity of its pursuer with a submission so unresisting, that it sometimes draws a tear even from the savage.

**A MAN LOST OVERBOARD.**—Extract of a letter from on board the United States ship Constitution:—

Four days out, as I was standing at the galley listening at the dash of the waves against the bridle ports, and watching the foaming flood that poured across the gun deck, I heard an unusual stir upon deck, and presently the cry of "a man overboard" was echoed throughout the ship.

It appears that the poor fellow was stationed upon the mainyard, and that in endeavoring to toggle the maintop bow line, he was struck by the flap of the sail and knocked overboard. The life buoy was cut adrift, the ship hove to, and the boat lowered as soon as possible, but alas! He gained the buoy worn out with his extraordinary exertions, gave it one slight grasp, and then went down to rise no more. And shall no one trace the epitaph of the seaman lost in the discharge of his duty? Shall the wild blast and the stormy petrel alone sing his requiem when the storm-cloud settles, and

"The Ocean leaps to own its God."

No! heaven forbid, the white stone shall yet rise in the corner of the village church yard in remembrance of him; and the aged mother as she stoops beneath the waving willow and reads—"Sacred to the memory of William Shaw, seaman, lost at sea,"—shall shed the tear of maternal sorrow there; and the young widow shall keep green the sod that covers the ideal grave of him, whose return she long expected when a foot trod heavily upon the threshold; or a voice unusual awoke the pensive stillness of the quiet home.

The frigate continued on her course, and for several hours a deep gloom prevailed every part of her: this dejection became more apparent when the name of the unfortunate man was called out at the grog-tub, and the old caterer of his mess answered in a low husky voice, "*He is drowned Sir.*"

Soon, however, the cheerfulness resumed her sway; then a violin was heard upon the berth deck, and then the dead and the peril of the storm were alike forgotten.

Sailors are a strange race—they weep when they do weep, as they pull a rope—that is with all their might; but when any one pipes belay, the grief of their spirit passes like a shadow away, and the future is no longer cared for; while the past is entirely forgotten.

The steamboat "Albany," which left Albany yesterday morning, was obliged to anchor at Catskill, in consequence of the breaking of some of the machinery; the passengers, 160 in number, were brought into this city by the North America, which arrived this morning.

The North America returned almost immediately, taking the day route of the Albany.

The President, it is said, has renounced his first purpose of going to Tennessee this summer, and will pass the hot months, instead, at the *Rip Raps*; where the sea-air and sea bathing will, it is hoped, reinvigorate his system.

**PARTNER WANTED.**

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to.

May-1

**RAILROAD JOURNAL AND ADVOCATE OF  
INTERNAL IMPROVEMENTS.**

This work is published once a week, in quarto form of EIGHT pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, IN ADVANCE. Previous volumes same price; full sets of four volumes, \$12.

**RAILROAD AND CANAL MAP.**

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$2.

**MECHANICS' MAGAZINE, AND REGISTER OF  
INVENTIONS AND IMPROVEMENTS.**

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, IN ADVANCE. Previous volumes \$1.50 each.

**NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.**

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

**QUARTERLY JOURNAL OF AGRICULTURE,  
MECHANICS, AND MANUFACTURES.**

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$5, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 220 pages.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher, D. K. MINOR, 35 Wall street, New-York.

**PUBLIC NOTICE.**

THE undersigned, Commissioners for the amelioration of the navigation of the Richelieu or Chambly River, will receive at their office, in the borough of St. Denis, on the 15th of June next, sealed propositions for the construction or erection of a Dam or *Chaussee*, with a Lock, to be erected about three miles above the village of St. Ours, either in Cut Stones, Common Stones, *Pierres Brutes*, or in Wood, according to the plans and specifications made by W. R. Hopkins, Esq., Engineer, deposited, and where they can be seen at any time, in the hands of Joseph Cartier, Esq., one of the said Commissioners, at St. Antoine.

All propositions addressed by the mail must be sent free of postage.

Two good securities will be required for the due execution of the aforesaid works.

Further information can be had at any time, from the undersigned, in addressing them at their respective residences, or from the said W. R. Hopkins, Esq., at Barker's Hotel, at the Chambly Basin.

ROCK IN ST. OURS, at St. Ours.

JOSEPH CARTIER, at St. Antoine.

JOS. T. DROLET, at St. Marc.

LA. C. DUVERT, at St. Charles.

L. F. DESCHAMBAULT, at St. Denis.

Office of the Commissioners, } 20—4t  
St. Denis, May 11, 1835.

The above Dam and Lock are in dimensions as follows: Lock 260 feet, Chamber 50 feet wide; Dam 675 feet long, 8 feet high.

Engineer Department of the New York }  
and Harlem Railroad, May 20, 1835.

THE RAILROAD CONTRACTORS.—Proposals will be received at this Department until the 29th of May, for Excavating a Tunnel through rock at Yorkville, from 18 to 24 feet in height, 24 feet wide, and 844 feet long.

For 15000 yds. of Rock, and 6000 yds. of Earth, north and south of the same.

Proposals will also be received for making an Open Cut Excavation where said Tunnel is proposed, which, together with other excavations, will amount to about 65,000 yds. of Rock, and 12,000 yds. of Earth.

Plans and specifications will be furnished 10 days previous to the time above mentioned.

The work will be required to proceed immediately after being put under contract, and to be completed by the 1st of December, 1835. Satisfactory security will be required of the contractors for the faithful performance of the work.

Communications may be addressed to the Engineer, at his office, No. 9 Chambers street. By order of the Board of Directors,  
JOHN EWEN, Jr., Engineer  
m2128 of the N. York & Harlem Railroad Co.

**MILL-DAM FOUNDRY**

ON MONDAY, June 1, at 12 o'clock, at City Hall, (unless previously disposed of at private sale,) will be sold by auction, the above well known establishment, situated one mile from Boston. The improvements consist of—

No. 1. *Boiler House*, 50 feet by 30 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. *Blacksmith's Shop*, 50 feet by 20; fitted with cranes for heavy work.

No. 3. *Locomotive House*, 54 feet by 25, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with slate, 120 feet by 46, containing two water-wheels, equal to 40 horse power; Machine Shop, filled with lathes, &c.; Pattern Shop; Rolling Mill and Furnaces, capable of rolling 4 tons of iron per diem, exclusive of other work; three Trip Hammers, one of which is very large; Engine for blowing Cupola Furnaces, moved by water-wheel; one very superior 12 horse Steam Engine, which could be dispensed with; and a variety of other machinery.

No. 5. An Iron Foundry, 80 feet by 45, with a superior air Furnace and two Cupolas, Core oven, Crane, &c. fitted for the largest work. Attached to the Foundry is a large ware-house, containing Patterns for the Castings of Hydraulic Presses, Locomotives and other Steam Engines. Lead Mill Rolls, Grinding Shafts, Saws, Grates, &c. &c. These were made of the most durable materials, under the direction of a very scientific and practical Engineer, and are supposed to be of great value.

No. 6. A building, 65 feet by 36, containing a large stock of chimneys, and furnaces, for making Cast Steel. This building is at present used as a boarding-house, and can accommodate a large number of men.

No. 7. A range of buildings, 200 feet long by 36, containing counting room, several store rooms, a Brass Foundry, room for cleaning castings, a large loft for storing patterns, stable for two horses, &c. &c.

The above establishment being on tide water, presents greater advantages for some kinds of business than any other in the United States. Coal and Iron can be carried from vessels in the harbors of Boston, to the wharf in front of the Factory, at 25 to 30 cents per ton. Some of the largest jobs of iron work have been completed at this establishment; among others, the great chain and lift pumps for freeing the Dry Dock at the Navy Yard and Charleston.

The situation for Railroad work is excellent, being in the angle formed by the crossing of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at these works. With the Patterns and Machinery now in the premises, 12 Locomotives and as many tenders, besides a great quantity of cars and wagons, could be made per annum.

For terms, apply to  
THOS. J. ECKLEY, Treasr. &c., Boston, or to  
ROBERT RALSTON, Jr., Philadelphia.  
Boston. April 21, 1835.

**RAILROAD CASTINGS.**

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads.

R-ly table

**RAILROAD CAR WHEELS AND BOXES,  
AND OTHER RAILROAD CASTINGS.**

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

**PATENT HAMMERED SHIP, BOAT, AND  
RAILROAD SPIKES.**

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y.

sept. 12-17

**RAILWAY IRON.**

95 tons of 1 inch by 1 inch, Flat Bars in lengths of 200 do. 1½ do. 14 to 15 feet, counter sunk 40 do. 1½ do. holes, ends cut at an angle 800 do. 2 do. of 45 degrees, with spli- 800 do. 2½ do. cing plates and nails to suit.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2½, 2¾, 3, 3½, 3¾, and 4 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. RALSTON

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them.

dtimeowr

**SURVEYORS' INSTRUMENTS.**

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

**SURVEYING AND ENGINEERING  
INSTRUMENTS.**

The subscriber manufactures all kinds of Instruments in his profession, warranted equally if not superior, in principle of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy; also a Railroad Goniometer, with two Telescopes, and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

Having recommendations are respectfully addressed to Engineers, Surveyors, and others interested.

Baltimore, 1832.

In reply to the inquiries respecting the instruments manufactured by me, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish the following information. The whole number of Levels now in possession of the department of construction of that road is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that the patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLES, Supt of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833. Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1833.

For a year past I have used instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY B. CAMPBELL, Eng. Philad.  
Germantown and Northern Railroad

## AMERICAN RAILROAD JOURNAL.

NEW YORK, MAY 30, 1835.

On our second page will be found another communication on the subject of *Railroad Locks*. We ask the attention of engineers to the subject, and should like to have the Journal made the medium of a discussion of its merits.

The observations on the Liverpool and Manchester Railroad will be found interesting.

The Report of a committee of the New-York Legislature recommending a geological survey of the State, should be read by all who take an interest in the development of the resources of the State.

**Potomac Aqueduct.**—A recent visit and personal inspection of the works of the Alexandria Canal Company at the Potomac Aqueduct, has given us new ideas of the magnitude of that undertaking—the extent of the difficulties that have been surmounted, and the labor and skill required in its construction. Scientific gentlemen, who have travelled much in this country and in Europe, assure us that no similar work was ever constructed in the United States, and in Europe but few of the governments have undertaken any thing to compare with it. What an exhibition does this present of individual enterprise!—we were about to say of heroic determination on the part of a community to sustain itself. If Congress does not come to the rescue of such a community and such a work, it will be lost to every principle of justice ; it will have forgotten the first of its duties.

Those of our citizens who have leisure and op-

portunity, ought to examine this great work in which we are now all engaged.—[Alexandria Gazette.]

[This stupendous work, being nothing less than a structure for carrying a large navigable canal over the Potomac river, at an elevation of some thirty or forty feet above its surface, is under the direction of Capt. William Turnbull of the U. S. Corps of Topographical Engineers, who, by the skilful manner in which he has so far overcome every difficulty in the prosecution of the work, has gratified all its friends, and removed the doubts of some who apprehended that the natural obstacles were too great to be surmounted.—[National Intelligencer.]

**SCHOOL OF CIVIL ENGINEERS.**—The trustees of Rensselaer Institute met on the 22d instant, to receive the statute passed the 9th instant, empowering them to organise a school of civil engineers as a branch of the Institute. Regular degrees of Civil Engineer are to be conferred by the President, Rev. Doct. Nott, in October annually, on those who are qualified theoretically and practically, and over 18 years of age. This is the first school of the kind ever organized on this continent. The Royal Military Academy at Woolwich, England, and the Polytechnia, in Paris, have branches nearly similar. Professor Eaton takes the immediate charge of this department ; Adj. Prof. Hall having been appointed to take the chief charge of the Natural Sciences. A very spirited corps of 6 or 8 young gentlemen have already entered the division, and will probably offer themselves for the degree of Civil Engineer in October. Two afternoons in each week will be devoted to the application of elementary principles to works in this vicinity, such as railroads, canals, bridges, water-works, mill-works, factories, &c. &c.

The Board of Trustees now consists of the eight appointed members from Albany, Troy, Lansingburgh and Waterford, (two from each,) with the addition made by the late statute of the Mayor, Recorder, and one Alderman of this city. The list of officers stands thus : Rev. E. Nott, D. D., President ; Judge David Buel, Vice President ; Hon. George Tibbitts, Hon. J. P. Cushman, William D. Haight, Esq., *ex-officio* ; Hon. Jesse Buel, and Philip Van Rensselaer, Esq. of Albany, Hon. J. D. Dickinson, and R. P. Hart, of Troy, are the Prudential Committee ; Elias Parmelee, Esq. and Rev. Phineas L. Whipple, of Lansingburgh, Gen. Guert Van Schoonhoven, and the Hon. John Cramer, of Waterford, constitute the Board

of Trustees ; Amos Eaton, Senior Professor, or and Agent, also Acting Professor of Civil Engineering ; Ebenezer Emmons, of Williams College, Junior Professor ; James Hall, Adjunct to the Junior Professor, and performing the duties of that office. Special Assistants are appointed temporarily. Dr. Moses Hale, Secretary, and H. N. Lockwood, Esq. Treasurer.

The degree of Bachelor of Arts, heretofore conferred on the general graduate, is changed to *Bachelor of Natural Science*. We consider this a good change, as the name is now more appropriate. The degree of Master of Arts is still retained as an honorary diploma for the general graduate, as well as the engineer, after three years of successful improvement in the useful application of his talent. E.—[Troy Daily Whig.]

To the Editor of the Railroad Journal:

DEAR SIR: In the statement which I gave you a few days since, relative to the route, as examined, of the Auburn and Syracuse Railroad, a comparison was instituted between that and some other roads. In that comparison the maximum inclination upon the portion of the Mohawk and Hudson Railway, between the inclined planes, was represented to be 37 feet per mile. This I obtained from a communication by L. De Witt Bloodgood, Esq. of Albany, to the Editor of the American Journal of Science, vol. xxi, p. 385. The facts in this article were "furnished by Mr. Jervis;" and being the only document to which I had access at the time of writing, I could not question their accuracy.

I have since ascertained by reference to the Railroad Manual, and to Smith's Appendix to Woods Treatise on Railroads, that the maximum inclination of the Road mentioned is 22 instead of 37 feet per mile, or 8 feet less per mile, than on the Auburn and Syracuse Road, instead of 7½ greater. This brings the average inclination upon the former 10½ feet per mile, differing insensibly from that of the latter, which is 10½.

The general conclusion in my communication will not be very materially affected by this correction—but believing that the maximum inclination on the Mohawk and Hudson Road was overrated, I am desirous of correcting the error.

Yours, very respectfully,

E. F. JOHNSON. ]

[For the American Railroad Journal.]

*On the Substitution of Locks for Inclined Planes on Railways, as applicable to the New-York and Erie Railroad.*

In a communication last week I endeavored to show the superiority of the railroad lock over any probable improvement of the locomotive engine, enabling it to propel its load over any considerable elevations. For in the latter case, there would be a liability, when the rails became smooth, and especially when covered with snow and ice, that the wheels of the engine would slide around in their places without rolling forward; and, even if this liability could be obviated, there must be a great waste of power. The engine must be sufficiently strong to carry its train up the steepest ascents on the road, and a greater part of its energies would therefore lie idle during the more level part of the journey.

These objections have heretofore been obviated by providing additional power to assist in these ascents; but the inclined plane generally employed in this case is liable to the greatest objections. Aside from the jeopardy in which life and property are placed in passing over these constructions, they have long been the subject of loud but almost hopeless complaint, and have even been characterised by writers on the subject, as "an opprobrium to the present advanced stage of civil engineering."

To say nothing of any other objection, the expense necessary to provide and keep in operation a stationary engine and its appendages is so enormous, that the necessity of constructing a very few of these is sufficient to render any contemplated route impracticable. I hardly need repeat, that the lock in question completely obviates this as well as many other difficulties. The locomotive engine raises itself and all its load at once, and by its own unassisted power. In this point of view, therefore, it will prove of almost incalculable importance.

This obstacle being thus removed, railroads can be constructed over routes now condemned as impracticable. But this is not all: the advantages arising from the successful introduction of these locks will not only appear from the change produced as to the practicability of entire routes, but also in that of their separate portions, where a road is deemed practicable. Still, in many of its sections, the difficulty of effecting a change of level occasions a very great circuitry of direction. Much of this may be avoided by the adoption of the locks in question, and the length as well as the expense of construction of the road be very materially diminished.

According to Williams' Register, the surveyed route of the New-York and Erie Railroad is 505 miles in extent, while the length of the mail route, passing through Newburgh, is only 415 miles. Now, had the latter left the Hudson at the same point as the contemplated railroad, that is to say, 24 miles from this city, the distance would have been still less, passing along one side of a triangle,

instead of two. I think therefore we may safely say, that the length of the surveyed route is 100 miles greater than a turnpike would be which should pass along the same general direction. This increase of distance has resulted, according to the report of the chief engineer upon the survey, from going around the high grounds instead of passing over them. Probably it would not be advisable to construct a railroad as direct as a turnpike. But suppose even 50 miles to be saved by the use of a moderate number of locks, and the mode of effecting this becomes an object of the most serious consideration. A diminution of one tenth of the whole length of the road, and of six or seven hundred thousand dollars in the expense of its construction, need only to appear practicable, to be regarded with the highest favor, not only by the proprietors of the work, but also by the public at large. The interest of the former in such a result is direct and immediate; that of the latter, although more remote and consequential, is nevertheless equally certain, since every diminution of the length of the road, or of the amount of expenditure, tends inevitably to diminish the cost of transportation.

It may be said that the increased accommodation afforded to the people of this State, from the increased length of a road winding through the valleys, removes the objections to this circuitry. Such a consideration would be of weight were the work intended merely for the benefit of those residing along its margin. But since it is designed as one of the great thoroughfares between the fertile and growing west, and its natural commercial emporium—since it must necessarily be brought into immediate competition with the other avenues of traffic between the Atlantic and the valley of the Mississippi,—and since the attainment of the object for which it is to be constructed consequently depends upon its presenting the most direct—convenient and economical channel of communication,—every mile by which its length may be diminished, every penny and every moment which may be subtracted from the expense and time of transportation, every facility and inducement for the direct conveyance of property from one extremity of the road to the other, becomes a matter of moment. Instead therefore of forcing the trade of the broad and productive regions of the west to flow through a circuitous channel, for the bare accommodation of a few New-York merchants and farmers, let that channel be made as straight as practicable, and let the convenience of our people at home be provided for by branches and auxiliary railroads.

It will also be objected, that the expense of constructing the locks themselves has been altogether omitted in the preceding general estimate. It will be seen on a future occasion that this expense will be far overbalanced by an advantage not yet enumerated, resulting from the introduction of the machine in question. M.

*Observations on the Liverpool and Manchester Railway. By Mr. David Stevenson, Edinburgh—Read before the Society of Arts for Scotland, on the 25th February, 1835.*

The improvement of railway communication is now a subject of so much importance, that any observations relative to the construction of railways, or the best mode of conducting traffic on them, especially such as are elicited in the course of practical trials, will generally meet with some share of public attention. I, therefore, venture to address to this Society a few observations upon the Liverpool and Manchester railway, the most remarkable work of the kind hitherto executed, both as regards the railway itself, and the means of traffic employed on it. These observations occurred to me during a late professional engagement on that work under Mr. Mackenzie, of Liverpool; and though I do not think it necessary to give a lengthened account of the railway, I trust some of the facts which I have collected will be found sufficiently interesting to excuse me for having brought them under the notice of the Society.

The Liverpool and Manchester railway was opened on the 15th of September, 1830. Its formation and construction, including the erection of lodges, depots, and offices, is said to have cost about one million sterling, or at the rate of £33,300 per mile; but as much of the work was not done by contract, this railway cannot be taken as a criterion of the expense of operations of this nature, which now are executed at a much lower rate.

The whole length of the main line is thirty miles. It forms a double way, composed of four single tracks of rails, having several branches to towns and collieries on either side. These branches, in most instances, consist of only a single way, with passing places. Connected with the main line, there are many works of importance and interest, including three tunnels, sixty-three bridges, and several cuttings and embankments of great extent. The drainage of Chert Moss, and the conveyance of the Railway over that bleak and uncultivated tract of country, are also particularly worthy of notice; but as accounts of these works have already been made public, I shall not farther notice them.

Excepting at Whiston and Sutton inclined-planes, where the inclination is at the rate of one foot perpendicular to ninety-six horizontal, there is no part of the Liverpool and Manchester Railway more than one in 880; and the curves in no instance deviate from the straight line more than four inches in the chain, or 66 feet. The inclination of one in 880 is hardly felt by the locomotive engines, and the curves are so gentle as to affect their progress very little. But the inclines of one in 96 on the main line, and several of the curves on the branch lines, prove formidable impediments, by diminishing the speed of the engines, and occasionally causing them to stop. The distance between the rails forming the tracks is 4 feet 8½ inches, and the distance between the two railroads or ways is the same. The rails are of that form technically called "fish-bellied" edge rails; they are made of malleable iron, in lengths of 15 feet, and weigh at the rate of 35 lbs. to the yard. They measure 2 inches in breadth at the top, 2¼ inches in depth at the chair, and 3¼ inches in the middle.

It is worthy of remark, that, when these rails break, the fracture is generally a few inches from the part resting in the chair;

and never in the thick part of the rail, between the points of support, which has led to the adoption of a parallel rail in all cases of repair. This rail weighs at the rate of 40 lbs. to the lineal yard. At every 3 feet the rails rest in a cast-iron chair, which, including keys and spikes, weighs about 16 lbs. The chairs rest upon stone blocks in the outtings where the ground is solid, and upon wooden sleepers on the embankments. The resting blocks contain 4 cubic feet of stone; two holes, 6 inches in depth and 1½ inch in diameter, are drilled in them, and into these, oak treenails are driven, to which the chairs are spiked. The sleepers are of oak or larch, and contain about 1½ cubic foot of timber; they measure from 8 to 10 feet in length, and being laid across the road, each sleeper gives support to both rails. When sleepers are used, a seat is cut in them for the chair, which is spiked down to them. A piece of cloth or felt dipped in pitch is generally interposed between the chair and the stone blocks, to make the seat more solid. The blocks occasionally split when the treenails are not driven home with care, but the sleepers are most frequently in want of repair and renewal.

The repair and keeping of the way was this year (1834) let by contract for £6000, being at the rate of £200 per mile. The contractor furnishes labor, chairs, keys and spikes, while the Railway Company furnish rails, blocks and sleepers. They calculate upon having to renew one chair per mile per day, and £720 per annum is taken as the outlay for keys and spikes. The workmen employed in repairing the rails, and keeping the road in good order, are called plate-layers, and the tear and wear is so great, that there is constant employment found for three men on every mile of the railway. The ballasting, in which the blocks and sleepers are embedded, consists of sand and broken stone, and forms a stratum two feet in thickness.

The Railway Company have had thirty-two locomotive carriages made, five or six of which are now out of use, and many of those at present on the road have been almost totally renewed. These carriages are all numbered and named. No. 1 is called the "Rocket." This engine was made by Messrs. Stephenson, the engineers, and is that which did them so much honor in carrying off the prize of £500, given by the Directors of the Liverpool and Manchester Railway for the best locomotive carriage. It has been little used, and is still in good repair.

The locomotive carriages used at present on the Railway are of three kinds, and are called train, luggage, and bank engines. The train engines average about 30 horses' power. They weigh about 8 tons, and cost about £900. The luggage engines are in general 35 horses' power, and weigh about 9 tons. They cost about £1000. There are only 2 bank engines, the "Goliath" and the "Samson," which are used for assisting the trains with passengers and luggage upon the inclined planes at Whiston and Rutton. They are about 50 horses' power, weigh about 12 tons, and cost about £1100. The cylinders of these different engines measure from 11 to 14 inches in diameter, and the length of stroke varies from 16 to 20 inches. The carriages used for conveying water and fuel for the engine are called tenders; they have 4 wheels, and are yoked behind the engines. They average, when loaded, about 4 tons weight, and cost about £150 each.

The principle on which the boilers are constructed is simple, and at the same time

very efficient. For this invention it is believed the Railway Company are indebted to their treasurer, Mr. Booth. The shell or outside coating of these boilers consists of sheet-iron, ¼ an inch in thickness. Brass tubes, 1-8 of an inch in thickness, and from 1 to 3 inches in diameter, are rivetted or fixed into the end plates of the boiler, and being open at both extremities allow the fire to pass freely through them. By this means a great surface of the water contained in the boiler and surrounding the tubes is exposed to the heat, and the steam is more quickly generated than in the common boilers. A steel ring, about 1-8 of an inch in thickness, 1 inch in breadth, and slightly tapered, is driven into the brass tube, after it is fitted into the boiler plate, by which means the tube is wedged against the plate, and thereby rendered water and steam tight. The tubes are proved by means of a water pressure of 50 lbs. on the square inch, and notwithstanding this, they frequently burst. When this accident happens, the engineer stops both ends of the broken tube with wooden plugs. The mechanics connected with the Railway prefer large tubes of 3 inches bore to the small ones, which are more apt to get choked with soot and ashes. The boilers are generally 7 feet long, and 4 feet in diameter, and contain about 70 or 80 of the small sized tubes. Round the boiler there is a lagging or casing of ½ an inch deal timber, fixed with iron hoops, which being a non-conductor, prevents the radiation of heat, and greatly facilitates the generation of steam, especially in frost, or in a damp state of the atmosphere. The time required for getting up the steam, even in the most improved boilers, is generally above an hour, when every thing is in a cold state. The Act of Parliament, in consequence of the smoke raised by pit coal, enforces the exclusive use of coke, which increases the expense of fuel about 40 per cent.

The cylinders are horizontal in all the locomotive carriages, with the exception of two, in which they are vertical, and these are not found to answer so well, and require more repair, the cause of which may be satisfactorily explained in the following manner:—When the cylinders are vertical, the machinery cannot yield to the up and down motion of the piston rod, and has consequently to bear the whole shock; while, on the other hand, when the cylinders are placed horizontally, the motion of the piston tends to impel the carriage along the rails, by which the shock is deadened, and has not so injurious an effect upon the machinery. The objection to horizontal cylinders, founded upon the more rapid abrasion of the lower side of the piston by the effect of gravity, is not found to have much force in practice. In some carriages the piston rods are connected to the outside of the two fore wheels; but in the improved engines they are connected to cranks on the axle of the carriage, in which case the cylinders are placed below the boiler, and are quite hid from view. On these engines also the wheels themselves are connected by rods, by which means the moving power is applied to four wheels instead of two, which doubles the adhesion of the carriage to the rails. The cross head at the end of the piston rod, working in a slide, produces the parallel motion. I may add, that some experiments were made on the Liverpool and Manchester Railway with Lord Dundonald's rotatory engine, which were so favorable a nature as to induce the Railway Company to construct a locomotive carriage on that principle. I have not, however,

heard whether their efforts to introduce the rotatory system have proved successful.

The fire-box consists of a double casing of metal, with an intervening space of about 4 inches. This space is filled with water, and has a free communication with the boiler, of which it may be said to form a part. It has a grated or ribbed bottom for holding the fuel, about 9 square feet in surface. The smoke-box and the funnel are made of iron, and are indispensable for catching the dust and embers blown through the tubes, carrying off the smoke and steam, and causing a draught for the combustion of the fuel. In the improved engines, the waste steam is ingeniously blown into the tender, and heats the water for the supply of the boiler.

The framing in some instances is made of cast iron, but more generally of wood. It rests upon the axles, and supports all the machinery, together with the boiler and its accompaniments. Connected with it, also are the springs for rendering the motion as smooth as possible for the machinery. The carriages have generally 4 wheels; the "Atlas," however, and some others, have 6. In some carriages all the wheels are of the same size, and about 5 feet in diameter, while others have 1 smaller pair of wheels about 4 feet in diameter. The axles and rims are of cast iron, and the spokes and tires of malleable iron. Sometimes, however, the greater part of the wheels, like the framing, is made of wood.

It was lately ment on locom engines more same or a great size of the wheel diameter were at the engines, but unsteady motion the liability of rails or break directly discount pany at present 3 feet in diameter. The greatest has been able to at per hour, with gine, with her to Manchester astonishing rat ding time lost in stoppages and ascending the inclined plane.

During wet weather are found to adhere in dry weather, but damp or greasy, the to slide instead of re then have considerable along their loads. A experiment, the ad the most unfavorabl equal to ¼th of the them. During frost generally placed bel off any ice or hoarf the rails. After the steam is thrown off, and the brake or drag applied, in order to stop the trains, the time that elapses before they cease to move is generally from 40 to 60 seconds, but this depends entirely on the state of the rails, and the rate at which the carriages are moving.

There are generally eight or ten engines at work on the line, each of which makes 4 trips a day between Liverpool and Manchester, and on coming in at night the steam is blown off, and the machinery is thoroughly cleaned. At each end of the line the company have a depot, consisting of sheds, where the engines are repaired at the sight of an overman or manager, and it is not a

little remarkable that 200 men are employed in keeping these engines in good order. The carriages are daily in want of some small repair, but they generally run about eighteen months before receiving a renewal, or thorough repair. The "Vulcan," a train engine, ran no less than 47,000 miles before it required to be taken into the shed for repairs, and the "Fire Fly" ran 50,000 miles. I have never seen any correct account of the work done by the several engines, or the repairs made on them. According, however, to the Railway Company's reports, the expenditure connected with locomotive power, exclusively of outlay for new engines, amounts to the extraordinary sum of about £28,000 per annum. On visiting the Stockton and Darlington Railway in the month of November last, I learned through the kindness of Messrs. Pearse, the promoters of this undertaking, that the engines running on that railway very seldom required repair; although in their construction, and the workmanship employed on them, they fall greatly short of those in use on the Liverpool and Manchester line. But at Darlington the rate of travelling is only 8 miles per hour, while at Liverpool 25 miles per hour is the usual speed; and hence we are fully warranted in supposing that the great wear and tear on the Liverpool and Manchester Railway may be chiefly attributed to the speed at which the engines are worked. Notwithstanding the smooth surface on which the carriages run, and application of springs, the tremor or shaking of the engines is very considerable, and is much increased with the speed. When moving at the rate of 25 or 30 miles per hour, the tremulous motion of the engine becomes quite alarming to those unaccustomed to it.

The luggage engines perform a great deal of work, and generally bring in 20 loaded wagons, averaging  $3\frac{1}{2}$  tons each. With this load they move easily at the rate of 20 miles per hour on every part of the Railway, excepting at Whiston and Sutton inclined planes, where the effect of gravity reduces their power 2-3ds, and forces them to bring their load to the summit at 2, and sometimes 3 trips, although assisted by the bank engines. They nevertheless make the journey between Liverpool and Manchester in about two hours. Upon one occasion, I saw the "Fury" engine with 12 loaded wagons, averaging  $3\frac{1}{2}$  tons each, ascend the Whiston inclined plane without the aid of the bank engine; its speed on the level was about 30 miles per hour, and when it reached the top of the incline, the velocity was diminished to about 2 or  $2\frac{1}{2}$  miles per hour. This inclined plane is a mile and a half in length, and its rise is at the rate of 1 in 96.

Some idea may be formed of the load these engines are capable of taking, and of the rate of charges and expense of fuel, from the fact, that, during my stay in Liverpool, the "Atlas" engine brought in 47 wagons, being a load of 160 tons, for which the Company's charge would be £70 sterling, or at the rate of £1.10s. per wagon. It is, I believe, calculated that the combustion of half a pound of coke will produce steam sufficient to carry 1 ton 1 mile, at the rate of travelling adopted on this Railway, so that the conveyance of 1 ton from Liverpool to Manchester requires about 15 lbs. of coke, the cost of which is about 2d. The expense, therefore, of fuel for bringing 160 from Manchester to Liverpool, according to this calculation, may be taken at £1.10s. while the Company's charge for carriage is £70, so that the chief expenditure, after the interest of the first cost of the Railway, is

in keeping the engines and Railway in repair.

The second-class train makes the journey in two hours, and has generally eight or ten carriages, which are open, and each seated for twenty-four persons. There are nineteen stations on the line where this train regularly stops, for the accommodation of passengers; and at each station there is a watchman, who makes signals if he sees cause for stopping the train. The signals are made during the day by red flags, and by lights after sunset.

The first class train makes only one stoppage, at Newton, to take in fuel and water, and performs the journey of thirty miles in an hour and a half. The coaches in this train are framed and covered like handsome road carriages, and are seated for eighteen passengers, with the exception of the railway mail coach, which goes at the end of the first class train, and is seated for twelve persons. The charge for passengers from Liverpool to Manchester by the first class train in the mail is 6s. 6d., and in the other carriages 5s. 6d. In the second class train, the fare, by the close carriages, 5s. 6d., and by the open ones 4s. The weight of luggage allowed to each passenger is 60 lbs., beyond which a charge is made at the rate of 3s. per cwt. The charge for conveying a four-wheeled road carriage is 20s., and a two-wheeled carriage 15s. On horse is charged 10s., two horses 18s., and three horses 22s. About one thousand and twenty passengers, and six hundred and forty tons of goods, are daily transported along the railway.

Each engine carries two men, an engineer and a fireman, who have respectively 5s. and 2s. 6d. a day. As a check upon their regularity, a fine of 2s. 6d. is imposed on the engineer for every fifteen minutes he arrives before his time. There is a brakeman with the luggage train, and the trains for passengers carry two guards.

The occurrence of accident is not so frequent as might be imagined, as the great weight of the carriages prevents them from easily starting off the rails; and so great is the momentum acquired by these heavy loads moving with such rapidity, that they easily pass over considerable obstacles. Even in those melancholy accidents where loss of life has been sustained, the bodies of the unfortunate sufferers, though run over by the wheels, have caused little irregularity in the motion, and the passengers in the carriages have not been sensible that any impediment has been encountered on the road. For the prevention of accident, some arrangements have been adopted, by which the north rails are exclusively allotted for engines going towards Liverpool.

The railway business is conducted by twelve directors, who give a half-yearly report on the income and expenditure; and a dividend of nine per cent. per annum has been declared for payment. At present, the railway is in use only during the day; but by conveying goods during the night, provision may be made for a great increase of traffic without incurring expense in the execution of new works.

Pittsburgh, Feb. 21, 1835.

The following report on the subject of a geological survey of this State ought to be generally published in the papers throughout the States. It abounds with sound, liberal, and enlightened views, and does honor to the committee who prepared it. In a word, it is full of truths of interesting

import, accurately and forcibly expressed. The memorial which drew forth this report proceeded from the American Institute of this city—an association of gentlemen unsparing in their exertions to promote science, as well as the useful arts. It is much to be regretted that their memorial for the construction of the Rochester and Olean Canal had not been favored with a sprinkling of the same intelligence and liberality.

*Report of the Select Committee on the Memorial of the American Institute.*

Mr. Clinch, from the select committee to which was referred the memorial of the American Institute of the city of New-York, praying for a geological survey of the State, reported:

The memorialists do not enter upon any detailed examination of the subject which they have presented for our consideration, but allude in general terms to the acknowledged obligations of government to advance the cause of science and of learning; and strenuously urge that efficient measures ought to be taken to promote the progress of this important branch of knowledge, inseparably connected as it is with a thorough disclosure of the internal resources of the State, and with the industry and enterprise of its citizens.

They remark that New-York has yet taken no steps towards an examination of the geological features of its extensive territory; and they forcibly present to the attention of the Legislature the example of our sister States of Maryland, Tennessee, New-Jersey, Massachusetts, and Virginia, in all of which scientific researches of this character have been instituted by law, and have resulted beneficially to the various interests in which the population are engaged, and with signal advantage to the promotion of the cause of science, particularly as regards the latter service, in the course pursued by Massachusetts; an enlarged edition of the geological researches of which State has been published by legislative authority, and presents a noble evidence of the liberal and enlightened policy of the government of that Commonwealth.

The memorialists further urge that the geology and mineralogy of our extended territory are prominent objects of useful and interesting inquiry, both in an economical and scientific point of view; and that a knowledge of the localities and extent of the different formations of quarries and minerals can only be acquired by the scientific researches of competent persons, the labor of which is altogether too onerous to be undertaken by individual enterprise, and involves an expenditure of time and money in the public service which can not be reasonably expected from the scientific institutions of the State, which have been established by private exertions and with limited means.

The memorialists conclude with suggesting the propriety of employing a commission, to be composed of three or four competent persons, under the public authority of the State, to make a complete geological and mineralogical survey of the whole of our territory; and to present the result of their labor and researches in a report to the Legislature, at as early a period as may be consistent with the full and just discharge of the task assigned to them.

In the last annual message of Governor Clinton, (and repeatedly in former messages,) legislative encouragement is earnestly recommended to be given to mineralogical

researches throughout the State, with a view to the discovery of coal, which, from various geological indications, it is asserted must exist within our limits. The importance of these investigations is dwelt upon with apparent anxiety, and made manifest by all the cogency of argument and perspicuous array of facts which usually accompanied the recommendation of measures of public policy from the same enlightened source. A select committee, to which this part of the message was referred, made an elaborate and learned report upon the subject, confirming by unerring evidences the fact of the existence of bituminous coal and other mines of mineral wealth in various sections of the State; and clearly demonstrating that there is a general uniformity and analogical connection prevailing in Europe and in this country with regard to the fossil and other geological formations, as yet known to both.

During the session of the Legislature of 1829, a memorial was presented from the Lyceum of Natural History in the city of New-York, praying for an inquiry into the expediency of instituting a search for bituminous coal within this State. This memorial was accompanied with a resolution recommendatory from the Common Council of that city. The select committee to which the memorial and resolution were referred, reported favorably and at length upon the subject. That committee ardently endeavored to impress upon the Legislature their own conviction that this department of science peculiarly deserves the encouragement of the government, inasmuch as the beneficial results of its pursuits, whatever degree of success may attend them, cannot be otherwise than shared by the whole community—opening new sources of power and profit to the State, through the genius, and industry, and enterprise of the people. It is well remarked by that committee, in reference to the particular branch of one subject to which their attention was directed, that Legislative authority and munificence would be nobly employed in giving encouragement to discoveries in that department of science which would find their way to every man's fire-side.

The reports of the committees above alluded to, dwell with great fluency upon the utility and necessity of instituting these examinations into the "bowels of the earth;" and eloquently appeal to the intelligence and patriotism of the Legislature for unprejudiced measures and liberal appropriations to accomplish such objects. (See Assembly Journal, 1828, 1829.)

Knowledge is power! If this be true in its general sense, how peculiarly forcible is its application to the scheme of political economy pursued by the government of every Commonwealth? The power to be derived from a thorough manifestation of the sources of industry within its own sphere of control, is a pre-requisite to the perfection of every system devised for the well-being of the governed. Tested by this sentiment, the power possessed by the State of New-York is yet in its infancy. The knowledge to be acquired from a complete geological survey of our territory cannot fail to have the happiest influence upon our increasing prosperity; and as a director of the energies of our inventive and spirited people; as furnishing a varied choice of pursuits to the indolent and capricious; or, to the partially incapable portion of a population, composed, and likely to be forever composed in some degree, of the adventurous and unfortunate of all nations, it will be an unceasing source of wealth to the State,

and of grace to the condition of its dense and variously characterized community.

It would be as difficult as it is believed to be unnecessary, to enumerate all the benefits which would accrue from a faithful geological survey of the State of New-York. Your committee are satisfied that legislative patronage cannot be extended to any one department of science that will conduce more decidedly to the individual interests of every inhabitant within our borders. Every man who cultivates an acre of land amongst us, must find himself wiser and wealthier in the sequel of an investigation, which will teach him where to direct his search for useful and valuable, though secret products of his land, and prevent his continuing to throw away time and money in fruitless exertions, which a proper knowledge previously obtained would have taught him never to have commenced.

The States of North Carolina, South Carolina and Pennsylvania, in addition to those already enumerated, have made legislative provisions for geological surveys within their respective territories; the results of all of which, as far as is known to your committee, have invariably been of a useful and valuable character.

Unerring data, acquired by the exertions of scientific men of both hemispheres, have satisfied them that the hidden riches of our own soil are as valuable and various as those already discovered in Europe.

We are as yet thoroughly acquainted with but a small portion of our salt district; and the bringing to light of vast beds of bituminous and anthracite coal, which are reasonably conjectured to exist in the neighborhood of our navigable streams, would in itself be a popular source of pride and profit to the State.

The geological features of our soil present in many particulars a very extraordinary aspect. The incongruous mass of materials, and the multitudinous variety of forms and things, of which the hills and valleys of a portion of our State are composed, were most graphically exhibited to our view by an eloquent member of this House, in a recent debate on the subject of internal improvement. It was ably and admirably said on that occasion, that this section of the State suggested to the mind of the intelligent observer, the idea of a "DEPOSITORY OF MATERIALS OUT OF WHICH TO MAKE WORLDS!" What mines of wealth may not this combined compression of nature's works now nurture in its bosom? A speculative and inquiring spirit may pursue this thought to the most brilliant conclusion, and yet not overstep the modesty of reality; for, as far as they are known, the certainties of science and the images of the imagination, in the contemplation of this subject, present the same picture to the mind.

It may not perhaps be available to inquire what influence an ample knowledge of the geological features of our whole State would have had upon this location of our great public works; but its important bearing upon the route of canals and railroads hereafter to be constructed, will be evident to all. The facility of excavating, the probable amount and materials of transportation, the economy and feasibility of the proposed works, and the proper character of them, are all subjects that will be most effectually illustrated by a general geological and mineralogical survey.

Another valuable consideration is, the beneficial effect which an intimate knowledge of our internal resources will exercise, in solving the doubts of those who ex-

perience difficulty in deciding upon the expediency of establishing the several prominent public improvements now under discussion.

But the most impressive view in which this subject presents itself to the minds of your committee is, that the principle of self protection, which justly receives so large a share of consideration in determining the public policy of the State, would be materially enlightened by the data derived from the proposed survey.

The question of defending ourselves against the internal improvements of our neighbors, by constructing works which will command the trade of adjacent territories, while it would lose none of its propriety, might cease to be a matter of paramount importance, in consequence of the disclosure of these fountains of industry and wealth now hid in darkness within our own soil.

Taking these general views of the subject, your committee are of opinion that the suggestions of the memorialists are in accordance with the soundest policy and best interests of the State; but your committee are not prepared to decide upon the best means of carrying these suggestions into effect.

Considering the late period of the session, they are willing to give the subject a progressive action during the recess of the Legislature, and have no objection to such disposition of it as will bring to its support the fostering care of an accomplished guardian; attract towards it that degree of general attention to which its importance is entitled; and give it the advantage of the volunteer aids of scientific men in all parts of the State.

Your committee have therefore unanimously agreed to propose the following resolution:

Resolved, That the Secretary of State be requested to report to the Legislature, at its next session, the most expedient method of obtaining a complete geological survey of the State, which shall furnish a scientific and perfect account of its rocks, soils and minerals, and of their localities, a list of all its mineralogical, botanical and zoological productions, and provide for procuring and preserving specimens of the same, together with an estimate of the expenses which may attend the prosecution of the design, and of the cost of publication of an edition of three thousand copies of the report, drawings, and geological map, of its results.

**SUSPENSION BRIDGES.**—At a meeting of the Clinton Suspension Bridge Committee last week, Mr. West's report on the principle of wire suspension bridges was read and approved. This gentleman has recently been examining the suspension bridges of France and Switzerland, most of which are of wire. He stated that previously to the opening of the Fribourg bridge, in October last, proof was made of its capability of sustaining great weight, by placing 36 horses, 14 pieces of artillery, and 300 people upon it at one time, which did not cause the slightest derangement in the structure. Upon the occasion of opening the bridge, a grand procession of the clergy and municipal authorities took place, when no less than 1,800 persons, estimated at 90 tons, were at once on the bridge. The two largest bridges over the Soane, at Lyons, are of wire, and are crossed by the heavy French diligences, weighing 5,000 lbs. each, and allowed by law to carry 8,000 more.—[English paper.]

(From the Journal of the Franklin Institute.)  
**Report to the Board of Directors of  
 Bridges, Public Roads, and Mines,  
 upon the Use of Heated Air in the Iron  
 Works of Scotland and England. By  
 M. DUBRENOY, Engineer of Mines.  
 Paris, 1884.**

(Continued from our last number.)

#### CALDER IRON WORKS.

These works are three miles from Glasgow, on the Edinburgh Road; the hot air blast has been used at them for three years past; two of the furnaces are fed by an apparatus like that at the Clyde Works, but at the other two the air is heated by means of a system of small tubes, represented in figures 8, 7, 8, and 9.

This apparatus is composed of two large horizontal tubes, *a c*, and *a' c'*, six feet long, nine inches in diameter in the clear, and one inch thick. Nine small tubes, six inches in diameter outside, and three inches inside, doubling upon each other like syphons, are placed vertically upon the pipes, *a c*, and *a' c'*, and fastened, by being driven tight into the throat, &c. This system of tubes is placed in a rectangular furnace, ten feet long, three feet wide, and twelve or fifteen feet high.

The care is direct action, of the furnace small and by fire rough the *p, h*, pass in spread among the tubes which it envelopes, gaining the chimney by the openings, *o, o, o*.

The temperature of the air is raised by this apparatus to 612° Fahr., as at the Clyde Works; the consumption of coal is 7 cwt. of coal per ton of iron produced.

It appears to be preferable. It takes less room; all tubes, it is true, in of the air passing his circumstance a little influence on its or expended by the blowing engine is not greater than that at the Clyde Works, and the pressure of the air is two pounds and three quarters per square inch.

The expense of construction is quite small. The greatest part of it is formed of cast iron, which can be replaced at the works in case of accident. The cost of construction is estimated at about \$150, requiring about seven tons of cast-iron—say about one and a half tons for the large pipes, and five and a half tons for the small tubes. By estimating the iron cast into pipes, at \$24 per ton, which is the average cost at the works using coal, the expense of each apparatus will be about as follows: Masonry, \$100; earthen parts of the furnace, \$60; casting pipes, \$168; total, \$328.

The expense will then be about \$656 for each smelting furnace. At Calder they estimate the cost at about \$168 to each layer. The apparatus at the Clyde

is much more expensive; the quantity of iron required is seventeen or eighteen tons, and the masonry twelve times as much as at the Calder Works.

The working of the furnaces present the same circumstances as those of the Clyde, and it is useless to repeat them; but to exhibit the progress of the introduction of hot air, we shall indicate,

#### 1. The consumption and products of

the Calder Furnace, worked with cold air and coke.

2. The expenses and products of the same furnace, fed with air heated to 300° Fahr., also consuming coke.

3. The same results from the use of hot air and crude coal, during the month of July last.

The results which follow are extracted from the books of the establishment.

Consumption and Produce of Furnace No. 3, in 1828, by the Use of the Cold Blast and of Coke.

Loss in Ore. ....		797 8 0					
Crude Ore. ....		1993 10 2	Pressure of air, 24 lbs.				

By comparing these tables, we learn that for one ton of iron produced, the furnace No. 3 consumed as follows:

#### 1828. Cold Air and Coke.

	t. c. q.
7075 of coke, corresponding to 15724 lbs. coal, or. ....	7 17 0
Ore roasted, 3798 lbs., or. ....	1 18 0
Ore crude, 5970 lbs., or. ....	2 19 2
Flux, 1330 lbs., or. ....	13 0

#### 1831. Air heated to 300° Fahr. and Coke.

	t. c. q.
4379 of coke, corresponding to 9510 lbs., or. ....	4 15 0
Fuel for heating the apparatus, valued at. ....	6 0

	t. c. q.
Ore roasted, 2317 lbs., or. ....	5 1 0
Ore crude, 4575 lbs., or. ....	1 2 0
Flux, 1260 lbs., or. ....	2 6 0
	13 2

#### 1833. Air heated to 612° Fahr. and Coal.

	t. c. q.
Coal crude, 4187 lbs., or. ....	2 2 0
Fuel for heating the apparatus, valued at. ....	8 0

	t. c. q.
Ore roasted, 3735 lbs., or. ....	2 10 0
Ore crude, 6228 lbs., or. ....	1 17 0
Flux, 573 lbs., or. ....	3 0 0
	5 2

Note.—The consumption for the steam engine is not considered.

The furnace has produced each twenty-four hours,

	t. cwt.
1828. Metal, 11,238 lbs., or. ....	5 12 1
1831. " 12,143 " or. ....	6 13
1833. " 16,438 " or. ....	8 4 1

The consumption of combustion has, therefore, diminished from 7 t. 17 cwt. to 2 t. 2 cwt., and the amount of flux from 13 cwt. per ton of iron in 1828, to 5½ cwt. in 1833. This diminution must be charged to the increased temperature in the furnace by the use of heated air. I will indicate at the close of this Report, the reasons which appear to me to account for this increase of temperature, the existence of which is certain, though we have not been able to measure it.

The quantity of air blast has been reduced from 3500 cubic feet per minute, to 2627 feet, the pressure being reduced from 3½ lbs. on the square inch, to 2½ lbs.

The expense of the fuel for heating the air varies from 7 to 8 cwt. per ton of iron.

The consumption for the blast engine remains the same, but as the yield of the furnace has advanced from 5 tons 12 cwt., to 8 tons 4 cwt., the expense, divided on each ton of iron, is reduced from 1 ton 4 cwt., to 14 cwt.; the slack only is used for this purpose.

The consumption of ore has varied much, but, as the scoria never contains more than from .02 to .015 of iron, this

difference depends on the quality of the ore, according as the *Ball ironstone* (mine eu rognous), or *flat ironstone* (mine eu couche), is used.

At Calder, as in the Clyde Works, the daily production of iron has been increased in a great proportion; this circumstance operates powerfully on the price of fabrication, as will be seen by the following statement.

*Cost of making one ton of Pig Iron at the Calder Works.*

1833. <i>Hot Air and Coke.</i>		
<i>l. cwt.</i>		<i>d. c.</i>
7 17½	coal for fusion, at 4s. 6d. per ton.....	8 50

		<b>11 38</b>

The blast engine employed at Calder is made with two cylinders, one over the other, with one shaft, so that the pistons of both are attached to the same beam, (*figs.*) The upper cylinder is fifty inches, and the lower cylinder seven feet, in diameter, each being seven feet long; the stroke of the piston, which is nine inches thick, is seven feet, and it makes sixteen strokes a minute.

## MONKLAND IRON WORKS, NEAR AIRDRE.

The heating apparatus used at this establishment is similar to that at Calder, being formed with two large pipes, and a number of small tubes, jointed in the large ones, the relative positions being changed.

The two large pipes, *a b, a' b'*, (*figs.* 4 and 5,) are vertical, and framed as shown in the plate. The small tubes, *c c*, five feet long, which make the communication between them, are placed horizontal. This difference of position, and diminished length of the tubes, prevent the temperature of the air from being raised so high as at Clyde, or Calder.

At the time I visited Monkland, the air was heated to 450° Fahr., and coke was still in use for smelting.

The economy in fuel and flux obtained at these works, since the introduction of hot air, is nearly the same as at the Calder works, when the air at that furnace was heated to 800° Fahr., and coke still used in the furnace.

Before the adoption of the new plan, the Monkland works consumed from seven to eight tons of coal, for each ton of metal; since that time, there has been consumed 4 tons of coal for smelting; 6 cwt. of coal for hot air apparatus; 3 tons 5 cwt. crude ore; 10 cwt. flux.

The daily yield is now six tons; the pressure of the blast, two and three quarters of a pound.

The metal produced in the three works of which I have given the details, is, for the most part, intended for the foundry; the No. 3 iron alone is made into bar iron, and for this purpose is sold to the forges near Newcastle.

The pig metal, Nos. 1 and 2, though both destined for the foundries, are not employed indifferently.

The No. 1 iron is principally used for castings, which are to be worked as steam cylinders, &c., or for those requiring great strength. The No. 2 iron, though easily cut with a chisel, is nevertheless harder than the No. 1; it is employed, in preference, for cog wheels, and work requiring considerable hardness.

Besides the works of which I have treated, three others exist in Scotland, using the hot air blast; the results obtained in these establishments, by the adoption of the new plan, being similar to those cited, it appears useless to enter into details respecting them.

## IRON WORKS IN THE ENVIRONS OF NEWCASTLE-ON-TYNE.

In the coal basin of Northumberland, the largest and richest in the kingdom, which furnishes almost all the fuel used in London, and the vicinity of the Thames, there are but two iron-works.

1st. The *Butterly Iron Works*, six miles from Newcastle, on the London road—the other called the *Tyne Iron Works*, on the banks of the Tyne, three miles from Newcastle. This region does not abound in good iron ore, and the proprietors have been unable, after the most minute search, to procure mineral enough to supply these two works; but their position on the banks of the Tyne enables them, in spite of these unfavorable circumstances, to draw their supplies from Lancashire and Cornwall, at a cheaper rate than they can be obtained, for the most part, in our iron works.

Both these works have used the heated air for a year past.

The *Butterly works*, constructed but three years since, contain two furnaces forty-five feet high, four reverberatory furnaces, and several cupolas; all the iron made is intended for castings.

The results given by the apparatus for heating the air, are not sufficiently important to warrant a particular description and plate. The apparatus consists merely of a tube, returned five times upon itself at right angles, and disposed so that the cross section presents five circles, of which four have for the centres the angles

of a rectangular parallelogram, and the fifth the point where the two diagonals intersect.

The tubes are placed horizontally, and are connected by bolts and nuts through lugs on the outside.

The interior diameter of these pipes is fourteen inches, and the metal one and a half inches thick; the length of the heated part is fifty feet, and the pipe is placed in a rectangular furnace, a little shorter than it, so that the joints and angles may not be exposed to the action of the fire.

The expenditure in fuel of this apparatus is about six hundred weight to the ton of iron produced. The pressure of the air is one and a half pound, being the same as before the introduction of the hot air. The velocity of the blast is a little less.

The charges of the furnace are as follows:

700 lbs. coke, (this coal gives 45 per cent. of coke;) 650 lbs. mineral roasted, being a mixture of equal parts of ore, (*mineral houiller*), and the red oxide of iron from Lancashire; 400 lbs. flux.

From the register, it appears that there were made, in furnace No. 1, July 10, 40 charges; July 11, 42 ditto; July 12, 38 ditto; or an average of 40.

The same furnace produced, in these three days, 23 tons 11 cwt. of metal, or a daily average of 7 tons 17 cwt.

By taking this data, we find that, to make one ton of iron at *Butterly*, they consume 4 tons of coal for fusion; 6 cwt. coal in lumps to heat the air; 1 ton 13 cwt. ore roasted; 1 ton flux.

The quantity of flux employed is very considerable, because it is much charged with water, being a marly chalk, brought from the banks of the Thames by the coal ships.

The mixture of ore, when roasted, contains 60 per cent. of iron.

To appreciate the saving which has resulted at the *Butterly works*, from the use of hot air, it is necessary to know exactly the consumption for a ton of iron, before the introduction of the plan. I have not been able to procure documents which would furnish this; but Mr. J. Hunt, the manager, assured me that the expenditure was seven tons of coal.

If we compare these results with those obtained in Scotland, we shall find that the consumption at *Butterly* corresponds nearly with that at Calder in 1830, when the temperature of the air was raised to 300° Fahr. and coke was still burned.

At Newcastle, the price of coal forbids

its use in the crude state, because the lumps, which are worth one dollar and forty cents the ton, must be used; while the slack, at forty cents, may be used to make coke for this purpose. It is nevertheless advantageous to give the air a higher temperature.

#### TYNE IRON WORKS.

The consumptions of material in this work, for the production of a ton of metal, are nearly the same as at Butterly; but an important difference existing between these establishments is, that, at the Tyne works, a great portion of the pig metal is made into malleable iron. This iron, which is of a superior quality, is almost exclusively rolled into boiler plates. In the same furnaces, and with the same minerals, the two kinds of iron are made by varying the relative proportions of ore and coke.

Cupolas are also fed with heated air to great advantage, 225 pounds of coke being sufficient to melt a ton of metal.

The furnaces having been constructed since the adoption of the hot air plan, no comparisons in regard to economy could be instituted.

#### ENVIRONS OF MANCHESTER AND LIVERPOOL.

The *Rant* iron works, near Wrexham, in Flintshire—the *Apdale*, the *Laneend*, and the *Silverdale* works, near Newcastle-under-Line, Staffordshire—have adopted the hot air plan.

The apparatus used in these establishments are very like those represented at figures 7 and 8. At *Apdale*, precisely the same apparatus is used, and the results obtained since its introduction are almost identically the same as at *Calder*, the temperature of the air being raised to 600 or 612° Fahr.

The consumption of coal, formerly six tons to the ton of iron, is now reduced to three and a quarter tons. They still employ coke, the coal being sulphurous. The expense of the heating apparatus is 7 cwt. of coal to the ton of iron.

The quantity of flux is reduced in the same proportion. In July, when I visited *Apdale*, only one furnace was in blast, which had been five years at work, but only six months with heated air. Since that time, the yield of the furnace has been from six to seven tons per day; the iron produced being almost all No. 1; while before, the metal had been nearly equal parts of No. 2 and No. 3, the last being made into bar iron.

One work near Newcastle, belonging to Mr. Furnstone, has abandoned the use of the hot air blast. I should have endeavored to ascertain the cause of this, had I learned the fact in time to visit the works.

(To be continued.)

[From an Essay of M. Arago on Artesian Wells.]

*Depths of the most remarkable Fountains which have been opened by the hand of man.*

We have already alluded to pits sunk by the Chinese to the depth of 1800 feet, in the province of *Kia-ting-fou*, by which they hoped to procure a supply of salt water; but as no water ascended the pits, we cannot rank them in the list of wells properly so called.

The seventh sheet of water, found near Saint Ni-

colas-d'Almermont, was at the depth of 1030 feet.—The water from it rose to the surface. As it was not water, but coal, that was sought for, the works were abandoned; and the only result that remained, was the formation, without intending it, of a copious fountain, whose waters issued from a source more than 1000 feet deep.

The pit recently sunk at Geneva to the depth of 682 feet, has not reached any body of water which has a tendency to rise.

At *Suresne*, near Paris, the residence of M. Rothschild, the Messrs Flachat have worked a pit, previously begun by M. Mulot, to the depth of 663 feet. This pit has now penetrated the chalk to the extent of 537 feet. The work has been suspended, when there is only 60 feet more of the chalk formation remaining, upon penetrating which, there would be every prospect of finding water.—The desirableness of prosecuting the research is most apparent.

The fountain of *Cheswick*, in the Duke of Northumberland's park, projects its water about a yard above the surface of the soil, and comes from the depth of 582 feet.

The deepest fountain in the department of *Pas de Calais* is situated between *Béthune* and *Aire*. Its waters project seven feet above the ground, and come from a depth of 461 feet.

The artesian well which affords such an abundant supply in the cavalry barracks at *Tours*, is fed by a body of water which M. Degoussé found at the depth 259 feet. The water of another well, which was finished in 1834, in the silk manufactory of M. Champoiseau, springs from a depth of 273 feet.

*Concerning the Daily Issues from some of the Principal Fountains.*

*Belidór* has already mentioned, in his *Science de l'Ingénieur*, a fountain which is situated in the manastory of *Saint André*, a couple of miles from *Aire* in *Artois*, the waters of which rise to the height of eleven feet above the ground-floors, and which furnishes nearly two tons of water per minute.

The well which Messrs. Fabre and *Esperiquette* have sunk, at *Bages*, near to *Perpignan*, in the property of M. Duvand, supplies 333 gallons per minute.

The well which M. Degoussé had sunk in the cavalry barracks at *Tours*, measured at six feet above the ground, furnishes 235 gallons per minute.

Of the many wells which exist in England, the one whence, according to my knowledge, there is the most abundant supply of water, is that in the copper manufactory of *Merton*, in *Surrey*; its issue amounts to 200 gallons a minute.

The artesian well of *Rivesaltes*, for which the inhabitants are so much indebted to Messrs. Fabre and *Esperiquette*, engineers, furnishes 176 gallons in the same time.

The well lately sunk near to *Lillers*, in the department of the *Pas-du-Calais*, with a depth of 140 feet, affords a supply of 155 gallons per minute.

*Of Artesian Wells whose waters have been employed as Moving Powers.*

At the village of *Gouéhem*, near *Béthune*, four wells have been sunk in a meadow to the depth of 190 feet. The waters which issue from them are converted into the water-course of a flour-mill, and subserve other agricultural processes.

At *Saint Pol*, there is another mill, the only moving power of which is the water from five projecting fountains.

At *Fontès*, near *Aire*, the waters of ten such wells are made to turn the mill-stones of a large mill, as also to blow the bellows and beat the hammers of a nail manufactory.

At *Tours*, M. Degoussé has excavated a well, in the silk manufactory of M. Champoiseau, to the depth of 430 feet, which pours 287 gallons of water per minute into the troughs of a wheel of twenty-one feet diameter. This wheel works the looms of his manufactory.

At *Tooting*, near *London*, the fountain of an apothecary puts a wheel of four feet diameter in motion, and this sets a pump to work, which raises water to the top of a house three stories high.

*Of the advantage to which Industry, in various circumstances, has turned the Waters of Fountains.*

On the present occasion we need not dilate on the benefits these waters confer on public health, nor on their use in irrigation, &c. &c. We shall only point out their application to a few purposes which are less generally known.

These springs have been put in requisition even

in countries where more common-courses are not unfrequent. Their constant and high temperature permits them to be applied to the movement of machinery during the most severe winters, whether it be directly, when they are abundant, or in other cases, only as a means of washing away the ice, which is apt to stop the movements of the water wheels.

In *Wurtemberg*, M. Bruckman, by transmitting through metallic pipes, conveniently placed, a current of water, at a temperature of 54 deg. Fahr., which is derived from several natural springs, keeps up a temperature at 47 deg., in various manufactories where the external cold lowers the thermometer to zero. This is a simple imitation of a plan which has been long practised in the village of *Claudes-Aiques*, the results, however, are worthy of consideration.

Greenhouses also are in existence, in which the temperature is maintained very equably, by the effects of the constant circulation of a large quantity of water, derived from these sources.

During heavy rains, the work of paper-mills is often interrupted, on account of the impurity of the water. These forced stoppages come to an end, when the constant limpid supply of a projecting fountain can be employed.

In some localities the invariable pure waters of a steady temperature, proceeding from these springs, have been the means of establishing very lucrative artificial cross-plots. The beautiful growth of cresses in those parts of the beds of rivulets where the natural springs existed, has suggested this application. It is positively stated that the artificial cross plots of *Erfurt* yield not less than 12,000*l.* per annum.

The very fine lint which is intended for the manufacture of cambric, lawn, lace, &c. is steeped in the *Department du Nord*, with very particular care. In a single *Commune*, between *Douai* and *Valenciennes*, there are ten or a dozen ratting-pools, which are fed entirely by water from a projecting fountain. It has been thought that the purity of these waters, and the invariability of their temperature, by accelerating the gum-rasins, preserve the valuable qualities of the filaments of the lint in the highest degree of perfection.

In fish ponds, the fish are apt to die during the winter, from the severity of the cold, and in summer from the heat. By turning the invariably temperate waters of an abundant artesian well into them, the extreme variations which the seasons induce are prevented. This experiment it is said, has entirely succeeded in the ponds of *St. Gratien*, near to *Montmorenci*.

*Sometimes Pits are sunk for the purpose of transmitting into the interior of the earth, water, retained at the surface by strata of impermeable clay or stone, and thereby rendering extensive districts mere morasses, unfit for cultivation.*

The pits by which descend into the interior of the earth those quantities of water which, without this expedient, remain on the surface, may be called *negative artesian wells*. Necessity, the mother of so many important inventions, early suggested to mankind the idea of imitating nature in this point.

The plain of *Paluns*, near *Marseilles*, used to be a great morass. It appeared impossible to drain it by the help of the common surface channels. King *René*, however, caused a great number of pits or drain-wells to be sunk, which are known in the *Provençal* language by the name of *embugs* (funnels). These pits transmitted, and now transmit, in the permeable strata situated at a certain depth, those waters which made the whole country a barren waste. It is positively stated that it is the waters taken down by these embugs of *Paluns*, which, after a subterranean course, form the projecting fountains of the port of *Mion*, near to *Cassis*.

The river *Orbe*, in the *Jura*, which descends from the lake of the *Rousses*, conveys into lake *Joux* much more water than evaporation removes from it. This latter lake, whence there issues no river, preserves, notwithstanding, a stated elevation which is nearly uniform. "It is," says *Saussure*, "because nature has provided for these waters subterranean issues, by which they are engulfed and disappear. \* \* \* \* As it is of the

\* It is the property of absorbing, of drinking up the surface waters, possessed by certain natural and artificial openings, which has given the names of *boit-tout*, of *betours* or *boitards*, to these drain-wells in certain districts.

greatest consequence for the inhabitants of this valley to preserve these natural drains, without which their arable lands and their habitations would be immediately overflowed, they preserve them with the greatest possible care; and when they perceive that they do not take off the water with sufficient velocity, they themselves open new ones. For this purpose, all that is necessary is to sink a pit fifteen or twenty feet, having a diameter of about 10 feet, in the thin and vertical strata, the summits of which appear on the surface. The name of *entonnoirs* (funnels) is given to these pits. \* \* \* \* It is," adds Savvure, "the waters absorbed by all these entonnoirs, that are observed to rise from the earth, and form a large spring, which is also called Orbe, at the distance of two miles below the southern extremity of the lake." In this passage of two miles, the absorbed waters descend 680 feet.

A manufacturer of potato starch at Villetaneuse, a small village about three miles from St. Denis, in the winter 1832-3, by means of a pit sunk to the depth of certain absorbing stratified beds, got rid of not less than 16,000 gallons of impure water per day, the stench from which had given rise to serious complaints, which probably would have compelled him to give up his establishment. After six months of daily absorption, nothing was found at the bottom of the pit except sand, and this has been uniformly the case from the first.

**Influence of Comets.**—"One of the most common effects attributed to these bodies is, an influence over the temperature of our seasons. It would be easy to expose such an error, by showing upon general physical principles, that there is no reason whatever why a comet should produce such an influence; but it will perhaps be more satisfactory to refute it by showing that it is not in conformity with observed facts. M. Arago has given a table, in which he has exhibited in one column the temperature of the weather at Paris for every year, from 1735 to 1801 inclusive; and in juxtaposition with these he has stated the number of comets which appeared, with their magnitude and general appearance. The result is, that no coincidence whatever, is observable between the temperatures or the number or appearance of the comets. For example, in 1737, although two comets appeared, the mean temperature was inferior to that of the preceding years, during which no comet appeared. The year 1765, in which no comet appeared, was hotter than the year 1766, when two comets appeared; the year 1775, when no comet appeared, was hotter than the year 1780, which was marked by the appearance of two comets; and the temperature was still lower in 1785, in which two comets appeared; while on the other hand the temperature of the year 1781 was greater, which was likewise marked by the appearance of two comets.

"This question, of the supposed connection between the temperature and the appearance of comets, has been completely sifted by M. Arago. He has given not only the general temperatures but also a table of the years of the greatest cold—of the years in which the Seine has been frozen over, and also of the years of the greatest heat—and he has shown that the corresponding appearances of comets have been varied without any connexion whatever with these vicissitudes of temperature.

"We should have hoped that the absurd influences attributed to comets would, at least in our times, have been confined to physical effects, in which the excuse of ignorance might be pleaded with a less sense of humiliation. But will it be believed that within a few years persons could be found among the better classes of society, and holding some literary and professional station—and in our own country too—who could attribute to the influence of comets every prevalent disease, local or general, by which, since the commencement of the Christian era, not the human race only was afflicted, but even the lower species of animals?

"The splendid comet of 1811 was, on the continent, considered as the immediate cause of the fine vintage of that year, and the produce was distinguished as the *wine of the comet*. But with us still more extraordinary effects were ascribed to that comet. In the 'Gentleman's Magazine' for 1818, we were told that its influence produced a mild winter, a moist spring, and a cold summer: that there was not sufficient sunshine to ripen the fruits of the earth; that, nevertheless (such was the cometic influence,) the harvest was abundant, and some species of fruits, such as melons and figs, were not only plentiful, but of a delicious flavor; that wasps rarely appeared, and *flies become blind*,

and died early in the season; that, in the neighborhood of London, numerous instances occurred of *women bearing twins*, and it even happened, in one instance, that the *wife of a shoemaker in Whitechapel had four children at a birth!*

So recently as the year 1829, a work appeared upon epidemic diseases, by Mr. Forster, an English practitioner, in which it is asserted that, since the Christian era, the most unhealthy periods have been precisely those in which some great comet appeared; that such appearances were accompanied by earthquakes, volcanic eruptions, and atmospheric commotions, while no comet has been observed during healthy periods. Not contented, however, with the influences formerly attributed to comets, Mr. Forster, says M. Arago, has so extended, in his learned catalogue, the circle of imputed cometary influences, that there is scarcely any phenomenon which he does not lay to their charge. Hot seasons and cold, tempests, earthquakes, volcanic eruptions, hail, rain, and snow, floods and droughts, famines, clouds of midgets and locusts, the plague, dysentery, the influenza, are all duly registered by Mr. Forster; and each affliction is assigned to its comet, whatever kingdom, city or village, the famine, pestilence, or other visitation, may have ravaged. In making thus, from year to year, a complete inventory of the misfortunes of this lower world, who would not have foreseen the impossibility of any comet approaching the earth, without finding some portion of its inhabitants suffering under some affliction; and who would not have granted at once, what Lubienietaki has written a large work to prove, that there never was a disaster without a comet, nor a comet without a disaster!

"Nevertheless, even the credulity and ingenuity of Mr. Forster were, in one or two cases, at fault, to discover corresponding afflictions for some of the most remarkable comets;—that of the year 1680, for example, which was not only one of the most brilliant of modern times, but the one which, of all others, approached nearest to the earth. The utmost delinquency with which he can charge this comet, was that of 'producing a cold winter, followed by a dry and warm summer, and of causing meteors in Germany.' To the comet of 1665, he ascribes the great plague of London; but he does not favor us with any reason why Edinburgh, Dublin, and Paris, not to mention various English towns and villages, were spared from its malign influence. The crowning absurdity, however, is the effect imputed to the comet of 1668. It appears, according to Mr. Forster, that the presence of this body made all the cats of Westphalia sick!"

**Locomotive Faculty of Plants.**—"If a wet sponge be placed near a cucumber which is growing in a particular direction, it will change this direction and grow towards the sponge. A plane-tree, growing on the top of a wall, directed its roots down the side till they reached the ground, a distance of ten feet, in order to obtain the requisite nourishment of which it was deprived in its elevated situation. Thus plants appear, like wise and intelligent agents, to move towards their good, and to turn aside from those soils that are either injurious or afford but a scanty nutriment.—[Analyst.]

A newspaper is a voice that will be heard; for, if it fail in its desperate effort to have its own way, and produce a desired effect, it gives up attempting to make the mountain come to it, and very wisely sides with the collected mass. It is the mirror of public opinion; not the original or fundamental creator, but the munificent distributor. You may be heartily sick of politics, commerce, and the rest of the perverse present; but the newspaper claims your ear as its prey, and remorselessly pursues you for ever. Dart away by the mail to escape from some detested news of Bourbon or St. Nicholas, and take shipping at the Land's-end, "the paper" goes with you; hide yourself where you will, it finds you out; it is the bellman of your social existence, your shadow, your familiar; in short, there is no evading it. The first house we set our foot in, on arriving in Mexico in 1825—a time of war, trouble, and yellow fever, and before speculators and travellers had ventured their lives and fortunes to work mines, or write a book—there sat the Vice-Consul's clerk, blowing swift clouds from a much-excited cigar, behind a copy of the incorrigible omnipresent *Times* newspaper.—[Examiner.]

The receipts for tolls on the New York canals during 30 days ending 14th inst. amounted to \$246,602; being \$51,580 more than had been received prior to the same date last year.

The stock of the Baltimore and Ohio Railroad Company, which has been for some time past steadily recovering from its depression, was yesterday sold at its par price of \$75 per share. Some sales are said to have been made at somewhat higher prices. There are various causes for this advance, among which we may briefly mention the appropriation by the State of two millions, for the completion of the canal to Cumberland—a work with which the railroad is now connected at two points, and will soon be at a third; the near completion of the Washington railroad, from the operations of which a handsome revenue is anticipated, and the completion, a month or two afterwards, of the Winchester Railroad, forming an extension of the Ohio road from Harper's Ferry thirty miles into the valley of Virginia. The understanding, also, that transfer books are about to be opened in Philadelphia and New York, has likewise contributed to enhance its value.—[Balt. Am. of May 16.]

Preparations are making at Brussels for opening the railroad from that city to Malines on May 1.—This is the first part of the line which is to run from Antwerp to the Prussian frontier. It is said that there are to be three steam-carriages differently laden. The first, which is called *La Fleche*, will contain the engineers and other persons who have been engaged in forming the road, and which will perform the passage in seventeen minutes. This will be followed by the Stephenson, impelling wagons filled with the Ministers, deputations from the Senate and Chamber of Representatives, and other officers of State; and in which will also be seated Mr. Stephenson, the English engineer, under whose direction the railroad has been formed. The third convoy of wagons will contain several hundreds of persons, drawn by an engine called the Elephant.

**Steamboat Improvements.**—"It is said in a *Ham-burgh Paper*, that Lord Cochrane's scheme for propelling vessels by quicksilver, instead of steam, is objected to, at St. Petersburg, on scientific grounds. It is asserted, that, if the plan were proved to be advantageous, in a mechanical point of view, it would still be impracticable. In support of this opinion, it is remarked, that no piston of a steam engine is so exactly fitted to its cylinder, as to prevent the passage of steam, and that every lubricating matter which might be applied, would, in the heat of the boiling mercury, at 600 degrees of Fahrenheit, be partly evaporated, partly carbonized. Moreover, no lubricating substance exists which is capable of obstructing the passage of the vapor, and its ascent, from quicksilver, would be greater than the ascent of steam. The atmosphere of the vessel would, therefore, be completely loaded with mercurial effluvia, and thus rendered highly dangerous to the health of the crew and the passengers.

The re-construction of Athens progresses. The first plan, which reserved half the old city for the purposes of excavation, and kept it free from the building of houses, has been abandoned, as ruinous to the already too much distressed inhabitants.—Liberty has been granted to build every where: 2000 houses are already standing, and 200 more are in progress; whilst in 1832 they amounted to not more than 700 or 800.

**DEMAND FOR COCOONS.**—Judging from appearances, the demand for cocoons and reeled silk, the coming season, will exceed the supply in a thousand fold. The silk manufactories in Dedham, Mansfield, and this city, are depending principally upon the new crop for the raw material. The last year's crop is already exhausted, and we understand that scarcely a bale of foreign silk can be found in the commercial cities. Those, therefore, who raise a crop this season may depend on its being sought for by the manufacturers and at a very liberal price. We should not be surprised if they command \$4 a bushel. Such persons, therefore, as have foliage, will do well to make cocoons, if they are not prepared for reeling.—[N. E. Farmer.]

## NEW-YORK AMERICAN.

MAY 23—29, 1835.

## LITERARY NOTICES.

**THE SIEGE OF VIENNA;** from the German of MDE. FICHLER. Philadelphia, KEY & BIDDLE.—We have not had leisure to look into this volume, —and only mention it now among the new publications, lest it should pass away without any review.

**OUTRE-MER,** a pilgrimage beyond the sea: 2 vols 12mo. New York, HARPER & BROTHERS.—The rambling, agreeable, scholarlike, meditations, comprised in these two handsomely printed volumes, appeared originally in numbers, and have been from time to time noticed in our columns.—Collected together, they make two volumes of agreeable reading; they are full of a gentle spirit and gentle influences.

**HISTORY OF THE REFORMED RELIGION IN FRANCE:** by the Rev. E. SMEDLEY, M. A. 3 vols. making vols. vii, viii, and ix, of the Theological Library, published by HARPER & BROTHERS.—It is a melancholy consideration, that the history of religion, in all countries, is a history of persecutions, blood, and crime. The religion of the gospel, has not escaped its full share of these accompaniments of human infirmity, and headlong passions. Nor has any sect, by which its precepts of "peace on earth, and good will to men," have been preached, been altogether free from the fierce spirit of intolerance and oppression.

In France, especially, the Reformed religion has from the beginning, struggled against fire and sword; against relentless power, exercised with all the cold atrocity of combined religious and political fanaticism—and to this day even—under the rule of a citizen king, and popular institutions, it is not on a level in consideration or influence, with the Catholic faith.

The history which Mr. Smedley has written, appears to us, elaborate, full of research, not partial, and conveyed in a very pleasing style. We make at random, an extract from vol. I. It relates the cold-blooded murder of the Prince of Condé, the Huguenot leader, after the disastrous battle of Jarnac.

It was not till the following March that any decisive military operation took place, and the two armies then met on the banks of the Charente.—The Duke of Anjou had been largely reinforced, and, aware that Condé was awaiting a powerful detachment of German auxiliaries, he determined to anticipate its arrival by an immediate attack. For that purpose it was necessary that the Charente should be passed; but of its two bridges, one at Jarnac was in possession of the Huguenots; the other at Chateaufort had been partially destroyed. The remains of the latter, however, being inadequately guarded, were repaired during the night, and crossed by the royalists on the morning of the 13th of March, before the admiral, who commanded the Huguenot vanguard, could assemble his division, which were scattered widely over the neighborhood. His intention, when he learned the advance of the royalists, was to fall back on the village of Bassac; but the tardy movements of some of his corps brought on a skirmish with his rear, which soon increased to a general battle.—Bassac was stoutly defended; but the royalists, who at first were driven back with much loss, at length carried and maintained it. When this reverse was announced to Condé, who being posted at some short distance had not hitherto been engaged, the brave prince was ill-circumstanced to afford assistance. In consequence of some previous hurt, he had entered the field with his arm supported in a sling, and as he rode along his lines, a severe kick from a mettlesome horse belonging to the Comte de la Rochefoucault shattered one of his legs in his boot. "Contending all sense of pain, and without changing the cadence of his tone and manner, he took this opportunity of inculcating a military lesson. "Gentlemen," he said, "bear in mind that fiery horses do more harm than good in action; and that it is but a silly vanity to pique ourselves on their management, and so to distract that at-

tention which ought to be directed altogether on the enemy—you may here see an unlucky proof of my doctrine, which however will not hinder me from fighting." Then waving his sword, he added, with greater fervor, "Nobles of France, know that the Prince of Condé, with a broken leg and his arm in a scarf has yet courage to give battle." After these words he rode briskly to the admiral's assistance; and charging with scarcely three hundred men at arms, he found himself unexpectedly opposed to the main body of the royalists. Surrounded, his horse killed under him, and himself disabled by his recent hurts, he beckoned two gentlemen of the enemy whom he recognised: and having surrendered his sword and received their faith for his security, he was raised from the ground, and seated under a tree. Almost at the same moment the Baron de Montesquieu, a Gascon gentleman and captain of the Swiss guards of the Duke of Anjou, rode up to the group, and asked who was the prisoner? Upon hearing that it was the Prince of Condé, he exclaimed with vehemence, "Sdeath, kill him, kill him!" and approaching closely behind his back, discharged a pistol through his head, by which he was instantly despatched.

There is too much reason to believe that this most atrocious and cold-blooded murder would never have been perpetrated had it not been well known that it would be approved by the Duke of Anjou. Young as was that prince (he had scarcely yet attained his eighteenth year), the seeds of those evil passions which afterwards rendered him the most detestable of his odious race, had already struck deep root in his bosom, and one among the most prolific of them was revenge. He was jealous of Condé's popular qualities, and apprehensive of his rivalry. There can be little doubt, even after rejecting the improbable details preserved by Brantome, that he had found in him a competitor for the highest military command; and we may attach full credit to another portion of that garrulous anecdote-monger's narrative, in which he proceeds to state that the Duke of Anjou had consented to peace solely for the purpose of entrapping the Prince of Condé, whom he hated with a hatred to describe which the English language has not an expression sufficiently strong, although we should say even unto death. "It was not likely to be otherwise," continues Brantome, remarking on the savage and treacherous conduct of Montesquieu, "for the prince, as I well knew, had been recommended to many of the favorites of Monsieur, on account of the hatred borne against him from the day which I have mentioned; and assuredly there is nothing which a great man abominates so much as another great man who is equal; unless it be one who is not so, and who yet endeavors to raise himself to equality."

The ungenerous treatment which the remains of the fallen prince received, corroborates the suspicion that his assassination may be ultimately charged on the Duke of Anjou. "Monsieur," says Brantome again, "was not at all displeased; but overjoyed, and wished to see his enemy's body after the conclusion of the battle. More out of insult than for any other other reason, it was thrown across an old she ass that happened to be at hand; carried to Jarnac with the legs and arms dangling on either side of the beast, and placed in a lower room under the chamber then occupied by the duke, and on the day before by the prince himself."—After having been thus brutally exhibited as a spectacle to the whole army, the body was in the end delivered to Condé's brother-in-law, the Duke of Longueville, and buried by the Prince of Bearne at Vendôme.

The next extract illustrates very strikingly the remark, made above, of the atrocious nature of fanaticism. Here the young Duke of Anjou, the king of France Charles IX, and the Pope, are seen exciting each other's zeal, to exterminate without remorse, and in the name, and for the sake, of religion, millions of their Christian fellow creatures.

The exultation of the youthful conqueror was boundless; and but for the discreet suggestion of one of his confidential officers, that he would thus accredit the rumor which imputed Condé's death to his express orders, he would have erected a chapel to mark the spot on which the prince had fallen. When the intelligence of the victory was conveyed to Metz, the temporary residence of the court, great joy, was manifested also in that city. On

the arrival of the courier at midnight, Charles arose from his couch to receive him, and proceeded immediately to the cathedral to celebrate a Te Deum. He then appointed a solemn service of thanksgiving throughout the kingdom; notified his success to all the crowned heads his allies; and laid the captured standards at the feet of the Pope.—Pius V. was loud in his acknowledgments, and addressed letters of congratulation in return to the chief personages of the French court. "When I received your most welcome messenger, my beloved son," were his words to the king, "announcing the victory gained by God's assistance over his enemies and those of the church, your rebellious subjects; and the death of the sources of all these troubles and seditions, the leader of the heretic army; raising my hands to Heaven, I gave thanks to the Almighty with all holiness of heart, for that He had vouchsafed you success, and had graciously poured out upon us also the riches of His loving kindness. But in proportion as God has dealt thus mercifully, so ought you with greater diligence and strenuousness to employ this opportunity, that you may follow up and destroy the remnant of the enemy; that you may utterly exterminate all the roots, and even the offshoots from the roots, of that so great and so confirmed evil.—If indeed they be not altogether eradicated, they will spring up again in quarters the least expected, as has often occurred before." Then, especially recommending the military occupation of Navarre, he urged Charles by the strongest exhortations to take from the common enemy all power of rising again. "This," he said, "will be best compassed, if you determine that no respect for human things or persons shall tempt you to spare the foes of God, by whom neither God nor yourself has ever yet been spared. You have indeed no other means of appeasing God, except by avenging most severely and with due punishment the injuries which He has endured from the most wicked of mankind;" and to that effect the example of Saul and the Amalekites was then propounded and applied. Similar incitements to persecution were repeated in a second letter, written about a fortnight afterward, in which the king was assured that tranquillity could be obtained for France by no other means than by insisting on unity of religious faith. "To procure that unity, under God's assistance, it is requisite that your majesty should proceed against God's enemies and your own, by just pains and penalties, exercising with severity the fullest rigor of the law. For if any motives should induce you (which we are far, however, from suspecting) to delay pursuit and vengeance, in those matters which give offense to God, you will deservedly provoke His long suffering to anger.—It is your duty to be deaf to every prayer, to reject every claim of clemency and kindness, to manifest yourself inexorable to every voice which may dare to petition for the most impious of men; and to that holy task, as it becomes our pastoral office and our paternal affection, well knowing that you are inclined to undertake it, we nevertheless think it fitting to stimulate you by this fatherly admonition."

Duplicates of these slaughter-breathing letters, with a few necessary variations of address, were at the same time transmitted to Catherine; and a hint was added that the Pope had heard of applications for the release of some of the heretic prisoners without punishment; a rumor which he confidentially trusted the queen would be able to contradict. To the Duke of Anjou, Pius wrote in terms of high compliment on his brilliant success in so early youth; urging him to follow up his victory with activity, and to exhort his royal brother to administer punishment unsperringly. But the pontiff's chief expressions of confidence and attachment were reserved for the Cardinal of Lorraine: "If there be any one," he said, "of those numerous illustrious Catholics by God's grace existing in France, who is to be congratulated more heartily than another on this seasonable victory, surely you are that person to whom we would peculiarly manifest our paternal sympathy. Not only because you are endowed with singular piety towards God, and are so deeply imbued with affection for the Catholic faith, that no one is likely to feel greater present joy, but because we know also that through God's assistance, it is mainly to your discreet counsels and wise suggestions that the Christian commonwealth of your kingdom is indebted for its prosperity." The remainder of the letter enjoins the cardinal, in a similar spirit to that which Pius displayed elsewhere, to exert every en-

egy, which he possessed for the suppression of any inclination to mercy which might chance to arise in the young king's bosom.

**THE TWO FRIENDS.** A Novel, by the COUNTESS OF BLESSINGTON. 2 vols. Philadelphia.—CAREY, LEA & BLANCHARD.—While recording the conversations of, and yet instinct with some of the inspiration derived from long residence with, Lord Byron, this titled lady wrote attractively—if not always with the spirit of truth. But in this novel, we see nothing to commend. It is the slip-slop of high life, and low morals.

**SPIRITUAL DESPOTISM,** by the author of the *Natural History of Enthusiasm*: 1 vol. New York, LEAVITT, LORD & Co.—This is a striking volume, at this period of time, for one of its chief aims is to counteract the tendency of opinion in England, to the overthrow of the Establishment. To accomplish this object, much learning and research—ability of argument, and moderation in stating it, are employed.

**THE ELEMENTS OF MORAL SCIENCE,** by FRANCIS WAYLAND, D. D., President of Brown University, and Professor of Moral Philosophy, 1 vol.: New-York, COOK & Co.—The use of Paley as a text book, and dissent from many of his doctrines, embodied at first in the form of objections orally made, and then in the views committed to writing with which, to the exclusion of those of Paley, President Wayland desired to imbue his students,—led to the preparation of this book:—a desire and hope, that what was found acceptable and instructive to his classes, may advance the general cause of moral science, induce the author to publish it.

It is a work of undoubted and profound ability, but it does not strike us as being, what the writer seems to consider it, an elementary book. Its arguments are sometimes too subtle and metaphysical, and at others assume too much knowledge and power of thought on the part of the reader, to make it a clear and easy work, for learners. To instructed or attentive minds, however, it offers abundant exercise.—and founding, as it rightly does, moral truth on the Scriptures, and considering, "that a system of ethics will be true, just in proportion as it develops the meaning of those Scriptures," it addresses itself to the highest hopes and interests of man.

The volume is well printed.

#### SUMMARY.

In the anniversary address of Professor Tucker, before the Virginia Historical Society, the following singular fact is mentioned, as connected with the History of Virginia.

In the year 1647, lawyers were forbidden to take any fees whatever, and 1658 they were excluded from the Legislature. For this uncourteous act, it must be confessed that their descendants have made the *amende honorable*. The medical profession seemed also an object of jealousy with the planters; as by another law (passed in 1646) physicians were required to swear to the value of their drugs.

**LAWS OF NEW YORK.**—The following summary from the Journal of Commerce, of some of the laws, passed at the late session of the Legislature, conveys all needful information, and saves us room.

An Act of the Legislature of New York, passed at the late session, provides that the affidavit of the printer or foreman of a newspaper, as to the publication of any advertisement in its columns, shall be entitled to be read in evidence in all Courts of Justice in this State, and shall be *prima facie* evidence of such publication.

Another Act authorises the Commissioners of highways to grant a written permission for Rail Roads to run across public roads when required.

Another Act directs all Banks in the State to

publish in two or more newspapers, an annual list of all deposits and dividends which at the date of the statement shall have remained unclaimed for two years next preceding. The first annual list is to be published on or before the 1st of September next.

Another act prohibits the sale of ardent spirits to paupers, or the purchase of any clothing from them furnished at the public expense, under penalty of \$5 for each offence, together (in the latter case) with the value of the clothing.

An Act was passed 23d of April, authorising the Common Council of this city to appoint an additional Police or Special Justice, making five in all,—at any time after the first of June ensuing, i. e. as soon as the Jackson Corporation have got well warm in their seats.

**AUCTION AND SALT DUTIES.**—The following proposed amendment to the Constitution having been agreed to by a majority of both branches of the Legislature in 1834, and also by a majority of both branches of the Legislature in 1836, is to be submitted to the people for ratification at the annual election on the first Monday of November next, and if adopted, will by that act become a part of the Constitution.

"Whenever a sufficient amount of money shall be collected and safely invested for the reimbursement of such part as may then be unpaid of the money borrowed for the construction of the Erie and Champlain canals, the tenth section of the seventh article of the Constitution of this State, so far as it relates to the amount of duties on the manufacture of salt, and the amount of duties on the goods sold at auction, shall cease and determine; and thereafter the duties on goods sold at auction, excepting therefrom the sum of thirty-three thousand five hundred dollars otherwise appropriated by the act of the fifteenth April, one thousand eight hundred and seventeen, and the duties on the manufacture of salt, shall be restored to the general fund."

[From the *Mercantile Advertiser*.]

A VERY BEAUTIFUL SIGHT.—There are now lying at Pine st. wharf, the new and superb ships WESTMINSTER and ST. JAMES, built for, and attached to, Mr. Griswold's and Grinnell, Minturn & Co.'s London Line of Packets. The former is commanded by Henry L. Champlin, and the latter by William S. Sebor, gentlemen well known and highly respected in their professional characters as well as in private life. Of the ships, all we can say is, that they are each of about six hundred and fifty tons burthen, built of the best materials, finished in the neatest and most approved style, and will take rank with the best of the fine packet ships of which we as New Yorkers are justly proud. The Westminster will sail on the 1st, and the St. James on the 10th June.

The Scotland, another superb new ship of 700 tons, intended for the Liverpool trade, and commanded by our esteemed friend Wm. G. Hackstaff, is now lying at Murray's wharf.

On beholding these ships, we think that every spectator will agree in the expression we have used for the caption of this article, that they have witnessed a very beautiful sight.

**Connecticut State Prison.**—From the annual report of the Directors of the Connecticut State Prison, it appears that the number of convicts in the prison at this time is 207, of whom 50 are blacks and 19 are females. They are employed in various branches of labor, viz:—23 in the carpenter's shop, 21 in the smith's shop, 45 in the chair shop, 22 in the Britannia ware, 7 as nurses and waiters, and 10 are invalids. The females are employed partly in the kitchen, and partly in making cigars. About half the convicts are let out by the day on contracts. The income last year from the labor of the convicts, including the receipts of visitors, amounted to \$17,384, making an average of \$91 50 for each. The whole amount of expenses for the year, including the support of prisoners and the expenses of the guard, was \$12,116, or an average of \$63 77 for each. The prison has therefore made a profit from the labor of the prisoners of \$5,268. The Directors propose that a separate block of cells, 15 or 20 in number, should be built, to be paid for out of the income of the prison. The prison is represented as well calculated for the safe keeping of the prisoners, no one having made his escape.—(Daily Adv.)

[From the *Canton Register*.]

**NEW PUBLICATION.**—We live in a literary age, and it would be a pity not to advert to the new lucubrations with which our celestial friends favor the world. Unlike the western barbarians, who wish to be wiser than their forefathers, Chinese scholars either repeat what the ancients have said, or are entirely silent, to give the world to understand, that they are too wise to think themselves wiser than the sages of the olden times. It is therefore very difficult to find a new publication, and it was mere chance that we got a small book into our hands entitled King-kwei-sin-shoo;—Warning to people of rank—a new book; or Sew-head-ke-tschen-chuen: The whole story of the elegant shoe, in four small volumes. Our readers are acquainted with the atrocities committed by Ye mangehe, the village tyrant, who was strangled in November last; a poet had contrived to write a ballad, wherein he paints the dreadful punishment of this miscreant in hades, and the present work is a relation in prose, interspersed with verses, which gives an account of the criminal's life after his return into his native village. The style of the work is easy, full of good aphorisms, the details are interspersed with some sage remarks, and wherever a simple relation of facts be too insipid, the author has availed himself of fiction, to render the work more amusing. We have perused the whole, and only regret that the writer has abbreviated so many characters, as to put the patience of the reader to a trial in finding them out. As a literary production, we think the author worthy of praise, for he has handled the subject with great ability, and given to the story romantic interest. The conclusion is as impressive as a Chinese writer possibly could draw it. The indignant spectators beheld the parting scene of Ye-mangehe from his wife, who shows the utmost tenderness towards an unworthy husband. As soon as his body is removed they resolve to retaliate upon his family the same injury which he and his accomplices inflicted upon the neighborhood. Such a proposal meets with general applause, until a senior amongst the crowd points out to the bystanders the punishment which he is now to receive in hades, according to the tenets of budhuism. This remark forcibly strikes them, and all acquiesce in the punishment of another world; the author recapitulates the sentences passed upon him and his accomplices in hades,—and concludes the whole with the moral of the story.

We have never read a work which has given us such an insight into the domestic life of the people of Canton. If these little volumes were translated they would surely please the English reader, who is anxious to know something about the Chinese.

**KENTUCKY LOAN.**—By an advertisement in this paper, it will be seen that Mr. Winter is here, with authority from the State of Kentucky, to borrow \$100,000, at 5 per cent, on bonds unredeemable for 20 years.

This is part of a loan authorised by the State to promote internal improvements, based on this solid foundation, that no advance of any part of it should be made, till double the sum be subscribed by individuals,—thus judiciously combining public and private interests. Kentucky owes not a dollar of debt—is a rich State—and will therefore doubtless obtain this loan on favorable terms.

**DEATH OF MR. BRONK.**—We regret to learn that JOHN L. BRONK, Esq. of Coxsackie, who was injured by the calamitous explosion on board the steamboat Advocate, after languishing nearly three weeks, died yesterday, at Coeymans.—[Albany Eve. Jour.]

**Wild Animals.**—The ship Susan arrived at Boston on Tuesday from the Cape of Good Hope, has brought the following rich cargo of wild animals, seventy-six in number, to Messrs. Macomber, Welsh, Gray, and Raynor, viz:—2 Elephants, 1 large Rhinoceros, 8 full grown Ostriches, 3 Bengal and 3 African Leopards, 6 white Vultures, 5 secretary Birds or serpent Eaters, 1 Cassowary bird, 3 laughing Hyenas, 2 strand or beach do., 3 spotted do., 1 Bengal or royal Tiger, 5 Porcupines, a full grown Lion and Lioness, 2 young do. do., 2 Jackalls, 1 Tiger cat, 1 Java Poney, 1 Mongoos, 2 Poonar or Hindestan Bears, 2 white and 1 crested Pelicans, 2 Zebras, 1 large Coffa Crana, 6 minor animals.

**A PUBLIC GALLERY OF THE FINE ARTS.**—The communication of *A Citizen*, in the N. Y. American, presents an appeal in behalf of the establishment of such a gallery in this city, and suggestions for carrying out the plan, which seem to us worthy of all encouragement.

It is understood that the venerable President of the Academy of Fine Arts, and many of his associates, fully concur in this project—of which the immediate effect would be—by putting before the eyes of our young artists, only good models—to refine and improve their talents; while on the public taste, it would exert that certain though gradual amelioration, which familiarity with the best productions of the pencil and the chisel, fails not to produce. We shall be well pleased, indeed, if the truly practical suggestions of our correspondent, attract the attention and co-operation of the public.

**A WINTER IN THE FAR WEST.**—As it is the fashion, in regard to all American works, to chronicle the opinions respecting them of the English press, we take from the London Morning Herald, the following really just notice of Mr. Hoffman's attractive volumes:

"This adds one more to the interesting works on America, which have of late proceeded from American pens. It is an account of an excursion made by the author through different portions of the Union, but chiefly along the Indian frontiers. He travelled amongst scenes, which were as new to him, as they are to his British readers, and had to rough it amongst the backwoodsmen, and scattered remnants of the red men tribes, even as an adventurer in the early days of the settlements. With a strong feeling for the beauties of nature, and the picturesque in every form, Mr. Hoffman is a writer of great vivacity and unaffected vigor. In a word, his book is full of matter the most various upon sober realities, and realities which savor of wild romance, and he narrates with a freshness of style which well becomes his unshackled theme."

We add these two extracts on the same subject from the *Court Magazine* and the *London Morning Post*.

[From the *Court Magazine*.]

"This is a most delightful book. No one has given a truer or more vivid description than Mr. Hoffman, of American wilds and American people. We can promise our readers a store of entertainment from these volumes."

[From the *Morning Post*.]

"This new work, by Mr. Hoffman, will be an acceptable offering to the general reader, and to all those who take an interest in comparing the impressions of an American traveller in reference to the scenes and society of the 'Far West' with the spirited but satirical sketches of Mrs. Trollope and Captain Basil Hall, and also to those who love nature in her undress, and find a philosophical gratification in tracing the elementary operation of the social systems in those remote regions which form the boundary between civilized and savage life. The narrative is very amusing. Over part of it, is diffused a tinge of romantic interest and adventure, arising from those numerous accidents by flood and field, that untaught heroism and unregulated energy, that habitual communing with nature in her wildest, perhaps her most attractive forms, which constitute the interest and the charm of semi-savage life."

**OHIO.**—The Governor of Ohio has summoned the Legislature of the State to meet on the 8th proximo. The following is his Proclamation:

"Whereas, great and weighty matters, claiming the consideration of the General Assembly of the State of Ohio, form an extraordinary occasion for convening them: I, ROBERT LUCAS, Governor and Commander-in-Chief of said State, do, by these presents, appoint Monday the eighth day of June next for their meeting at the city of Columbus, within said State, hereby requiring the respective Senators and Representatives then and there to convene in General Assembly, in order to receive such communications as may then be made to them, and to consult and determine on such measures, as in their wisdom, may be deemed meet for the welfare of the State of Ohio.

"In testimony whereof," &c.

**Attempted Balloon Ascent at Brooklyn.**—Yesterday evening Mr. Henry Prince, a young man who is a machinist at Brooklyn, attempted to ascend in a balloon from a piece of ground which was enclosed for the purpose with boards ten or twelve feet high, at the junction of Fulton and Clinton streets. Mr. Prince unfortunately, a few evenings back, exhibited his balloon gratis, in a large room, where some evil minded person cut it in two places, which Mr. Prince repaired, but as it turned out, not sufficiently well to retain the gas, which prevented his making his intended ascent. The inefficiency of the balloon was not discovered until after a considerable number of persons had entered the enclosure, and paid fifty cents each, for admission. As soon as Mr. Prince discovered that he would be unable to make the ascent, he addressed the persons who had paid their money, and told them they could get back their tickets on going out. A number of ruffians who were outside the enclosure, and had paid nothing, immediately knocked down the boards which formed the enclosure, and got inside and demanded the price of the tickets. Mr. Prince remonstrated with them, and an altercation ensued, which ended in his being obliged to take refuge in a neighboring house, to avoid the threatened violence of the mob. Mr. Prince has lost about \$300 by the transaction, but he is nevertheless determined to risk another ascent in an open field, leaving it to the public to remunerate him as they may think proper.—[Jour. of Com.]

The Cincinnati aeronaut, Mr. Clayton, who was to essay a visit in his balloon, to the sea-board some days ago, was cut short in his voyage at the outset. Owing to the violence of the wind, the balloon was snatched from the grasp of those who held the cord, before it had obtained sufficient upward elevation to avoid the houses, &c., and was consequently dashed against them with violence, endangering the life of Mr. Clayton. Fortunately, the car was, by one of the those concussions, separated from the balloon, and left with Mr. C. on the top of a house—the balloon winging its way into illimitable space. Mr. C. was not hurt.

A public meeting was afterwards held at Cincinnati, Bellamy Storer in the chair, at which it was resolved to raise by subscription a sum sufficient to indemnify Mr. Clayton for his loss. On his part, he is resolute in his purpose to make us Cis-Alleghians, a visit by balloon.

**WHALING WITH PRUSSIC ACID.**—It appears by the Nantucket Inquirer that the "novel" and "ingenious" scheme for killing whales by means of prussic acid, for which Mr. Chamberlain, of Boston, has "secured a patent", is none other than the invention of Mr. William Coffin, Jr. of Nantucket.—The Inquirer says:

"Over two years since, having observed the instantaneously fatal operation of prussic acid upon the vital powers of several small animals, Mr. Coffin was led to consider its probable effect upon those enormous creatures which it is the peculiar business of this community to pursue and capture. He forthwith caused several harpoons to be constructed, precisely on the principle now described in the article referred to—each provided with a small phial of the 'horrible liquid.' No opportunity for a proper experiment with this formidable weapon has ever yet occurred—for the reason that whalemen generally are apprehensive, and perhaps with good reason, of danger to themselves in its use.—But in the month of July, 1833, when great interest was excited by the alleged appearance of the Sea Serpent in Massachusetts Bay, a vessel was fitted out from this port, for the express purpose of taking that monster dead or alive, should it be fallen in with. On recurring to our files, we find in a notice of the departure of this vessel, the following paragraph:

"Among the implements of destruction on board, are sundry harpoons of new construction, one thrust from which will produce instant death. This description of harpoon carries within its barb a dose of concentrated poison, the most subtle which human science has yet been able to discover."

This vessel proceeded to Boston, where the nature of the weapons prepared was explained freely to many individuals: and we are inclined to sus-

pect that this was the origin of that "very novel scheme," that "unique discovery," made by an "uncommonly ingenious" manufacturer of "hooks and eyes." There may exist a natural connexion between these two branches of ingenuity; for the idea of "hooks and eyes" may have suggested the notion looking up the discoveries of other people's eyes. But

"Canst thou draw out Leviathan with an hook?"

It becomes our painful duty, says the Wilmington N. C. Advertiser, to record the death of Major George Blaney, of the U. S. Corps of Engineers, who expired at Smithville, on Friday, the 15th instant, aged 39 years. Major Blaney was a gentleman and a man of honor, in the full and legitimate import of the terms,

**Michigan Convention.**—The delegates chosen with a view, to the formation of a constitution for the Territory of Michigan, assembled in convention at Detroit, on the 11th inst. John Biddle was appointed president of the convention by resolution, and Mr. J. Bacon and Chas. W. Wipple, secretaries.

It is a singular coincidence that our French losses sustained by the decrees of the Emperor Napoleon, should have, at this late day, been indemnified by the French government, and that the first news of the important event should have reached here by the *Napoleon*.—[Gazette.]

[From the *Daily Advertiser*.]

**LITERARY.**—We have permission to publish the following extracts from the minutes of the American Lyceum, at their late fifth Annual Meeting.—The subject is interesting to all friendly to education, particularly female education in our country. We understand that the reading of the paper mentioned excited the warm and general gratification of the Society, and called forth several speeches from members.

"New York, May 9th, 1835.

**Morning Session.**—President Duer read the Essay of Miss Catharine E. Beecher, of Ohio, on the Education of Female Teachers.

On motion of Judge Radcliffe, seconded by the Rev. Mr. Johnson of Brooklyn, it was unanimously

Resolved, That the thanks of the American Lyceum be presented to Miss Catharine E. Beecher for her Essay on the Education of Female Teachers.

Resolved, That the Lyceum, considering the extensive circulation of this Essay, to be well calculated to excite public attention to the importance of its object, and the sentiments it contains particularly important at this time would recommend it to the public, and request those connected with the popular press to aid in its promulgation, by publishing extracts.

Resolved, That the subject of Female Education deserves more attention than it has yet received from the American community.

Resolved, That the establishment and liberal endowment of a considerable number of female seminaries for a high order, especially for the education of female teachers, is highly deserving of the benefactions of the intelligent and wealthy of the community, as well as of Legislative patronage.

Resolved, That the thanks of the Lyceum be presented to the Ladies who have undertaken to defray the expense of publishing the address.

True copy from the Minutes.

(Signed)

R. G. RANKIN, Sec. pro tem.

[From the *Buffalo Com. Adv. of Wednesday*.]

**MELANCHOLY LOSS OF LIFE.**—Early yesterday morning, two men named Brailey and Bailey, who were attempting to pass down the Niagara river, from Tonawanta to Chippewa, U. C., were carried by a sudden gust of wind into the rapids above the falls. In this alarming situation they deserted the scow, and swam for a temporary refuge to the shoals, about one and a half miles from shore. On this precarious footing, up to their necks in water, a rapid current sweeping around them, threatening to bear them to the awful brink below, these unfortunate men maintained their position for some time, shouting for assistance. A man named Udell put off alone, in a boat, to their relief; but one of his oars broke, and he was obliged to scull back with the other. Brailey then swam to a floating log, on which he attempted to reach the shore, but was carried downward by the irresistible current and

precipitated into the frightful gulf below. A brother of Udell's now volunteered to aid in the attempt to save the remaining sufferer; and furnished with two oars each, they again put off, and succeeded in rescuing the helpless Bailey from his perilous situation.

We hope the neighborhood will, by some public testimonial, honor the benevolent gallantry of these two Udells. Theirs was a noble daring, from the purest motives.—(Ed. N. Y. AMER.)

**CITY FINANCES.**—The Annual Message of the Mayor, ordered to be printed on the 18th instant, was laid on the table of the members. The following is a statement of the financial concerns of the city:

The city debt permanent and temporary is	\$745,034
Paid off during 1834	91,309
Warrants on the Treasury last year	1,915,638
Probable drafts next year, including water	3,000,000
Sinking fund on hand	130,900
Real Estate owned by the city	10,000,000

Miss Landon says "a quotation aptly expressed, is as good as an original thought;" we never met with a more forcible argument in favor of that thesis than the following from Brooks' Winchester Republican:—

"Hope wither in fled, and massa sigh'd farewell!"

An advertiser in Virginia offers a reward for the apprehension of a mulatto named Hope Witherin, who has practically illustrated the line at the head of this paragraph by obsequiating bodycausely.

**Punishing Extraordinary.**—A friend of ours received the following communication through the Post office:—[Charleston Courier.]

If Abel had been able to cane Cain, Cain would not have been able to cane Abel; Abel would therefore not have been Cane-Abel. CANE-ABLE.

**LATER FROM EUROPE.**—After a long interval, we have intelligence from France and England nine or ten days later than before. The packet ship *Osmada* from London, arrived on Saturday evening, with papers of the 18th from that city. The *Rhode Island* from Havre with Paris dates of the 14th, arrived yesterday, as did the *South America* from Liverpool of the 16th, and Cork of the 22d—having put into the latter port by reason of Captain Waterman's accidentally breaking his leg.

**New Ministry.**—We have great pleasure in announcing, that whatever difficulties may have existed appear to have been altogether overcome, and that Lord Melbourne has been able to form a Cabinet, which we have no doubt, will give entire satisfaction to the country.

The following is a list of the Members of the Cabinet, formed from rumors the most worthy of credit, which have reached us, and which have been in circulation days past. We trust it will prove to be correct.

**In the Cabinet.**—First Lord of the Treasury, Viscount Melbourne.

President of the Council, Marquis of Lansdowne.

Secretary of State for the Home Department, Lord John Russell.

Secretary of State for the Foreign Department, Viscount Palmerston.

Secretary of State for the Colonies, Right Hon. Charles Grant.

Chancellor of the Exchequer, Right Hon. T. Spring Rice.

President of the Board of Control, Right Hon. Sir J. C. Hobhouse.

First Lord of the Admiralty, Lord Auckland.

Chancellor of the Duchy of Lancaster, Lord Holland.

Privy Seal and Woods and Forests, Viscount Duncannon.

Secretary at War, Viscount Howick.

President of the Board of Trade, Right Hon. C. Poulett Thomas.

If we are not misled as to the members of the Cabinet, it will thus appear, that their number is considerably smaller than during the late Administrations, which we consider a more advantageous arrangement for the transaction of the business of the nation.

Sir Robert Peel and the Duke of Wellington did

not remain at the place above ten minutes. There was some cheering on their departure.

Lord Melbourne was loudly cheered on his arrival at the Palace.—[Courier.]

**LATER AND DECISIVE** intelligence from Europe, by the *Napoleon*, Liverpool packet ship of the 24th, was received last night. It confirmed the confident prediction we hazarded in yesterday's paper, that not "many hours, probably, would elapse," before hearing that the Indemnity Bill had passed.

It has passed by the extraordinary majority of 289 to 187. The condition annexed is a mere salvo to national feeling, and will easily be disposed of on our behalf, by a simple reference to, and repetition of, the language of the President's Message.

The amendment of Gen. Valaze, which was adopted, is to this effect:

"The payments to be effected in execution of the first article of the present Bill, shall take place only after the French Government shall have received satisfactory explanations as to the Message of the President of the United States, dated December 2, 1834."

Now it would be a full and complete answer on our part, to the requisition of this amendment, to recall and reiterate the following declaration, which, in the President's annual message, immediately follows the recommendation, that, in a certain contingency, reprisals be resorted to.

"Such a measure ought not to be considered by France as a menace. Her pride and power are too well known, to expect any thing from her fears, and preclude the necessity of a declaration, that nothing partaking of the character of intimidation, is intended by us."

What was said in good faith in December last, there can be no sort of objection to repeating, with increased emphasis, if necessary, now—especially as a resort to the alternative, to which this language, when used, referred, has been rendered unnecessary, by the compliance of the French Government with our reasonable demands.

A silly, blustering, paragraph, in the Liverpool Journal, which talks about this country being called upon to make an apology, has no foundation in fact.

This embarrassing question may, therefore, be considered as finally settled; and without now inquiring, where the merit of, or the obstacles to, an earlier and less ungracious solution of the difficulty, belong, we sincerely congratulate the country on the result.

Mr. Livingston will now, according to his orders, return, we presume, to the United States, rather than retire to Holland, or any neighboring country—leaving a *Chargé* in Paris.

The Constitution will, of course, proceed to her station in the Mediterranean.

The Queen of the Belgians has given another *Prince* to her people!—and they rejoice accordingly.

In English affairs there is nothing new by this arrival.

WHITEHALL, April 8, 1835.

The King has been pleased to direct letters patent to be passed under the Great Seal, granting the dignity of a Baron of the United Kingdom of Great Britain and Ireland unto the Right Honorable Alexander Baring, of the Grange, in the county of Southampton, and the heirs male of his body lawfully begotten, by the name, style, and title of Baron Ashburton, of Ashburton, in the county of Devon.

There are at this moment as many as eight ex-Chancellors of the Exchequer living:—Lord Sidmouth, the Marquis of Lansdowne, Lord Bexley, (who held that office 11 years,) Earl of Ripon, Mr. Herries, Mr. Goulburn, Earl Spencer, and Sir Robert Peel. The number of persons living who have held the office of Premier, or first Lord of the Treasury, is six:—Lord Sidmouth, the Earl of Ripon, the Duke of Wellington, Earl Grey, Lord Melbourne, and Sir Robert Peel.

Sir Robert Peel's administration was the shortest known in England, at least since 1760, the date of the accession of George the Third. It lasted only 118 days; the other short ones during that period were that of Lord Shelbourne in 1782, which lasted five days longer—that of Mr. Canning, the duration of which was 135—and that of the Earl of Ripon, which was 152 days. The duration of Lord Melbourne's first administration was 186 days.

The only pensions granted by Sir Robert Peel during his administration, excepting one of 100*l.* per annum to the widow of Mr. Temple, late Governor of Sierra Leone, are the following:—Professor Airy, 300*l.*; Mr. Southey, 300*l.*; Mrs. Somerville, 200*l.*; James Montgomery, 150*l.*; Sharon Turner, 200*l.* This, we presume, is proof of Conservative profligacy in the administration of patronage—of Sir Robert Peel's disregard of literary merit, and of his desire to repress literary exertion. But stop, the pensioners are all Tories? No; the majority are Whigs. We should like to see what Sir Robert's predecessors for four years can set off against these pensions.—[Standard.]

Lady Byron, widow of the noble poet, has broken up her establishment at Hanger Wood, near Acton, preparatory to her departure with her daughter, the Hon. Ada Augusta Byron, on a tour for the summer in France and Italy.

The French chemists make the following proposition, in order to render less frequent the crime of poisoning, and to put on their guard those who may be marked out as the victims of revenge, jealousy, or the like. From 1824 to 1832, the number of individuals accused of poisoning was 273; and it appeared, that in many instances the intended victims had been saved by the bad taste communicated to the food by the poisonous substance. It is, therefore, recommended that it should be rendered compulsory to color or give a flavor to all poisonous substances which would not be deteriorated by the admixture. For the latter purpose, aloes have been suggested; and of this many English as well as French chemists have approved. It has also been recommended to scent all poisons with the same odor—musk, for instance.

In Spain, the battle between the contending parties lingers along. *Mina* has been displaced from the command of the Queen's troops, and we rejoice at it, for hitherto his only feats seem to have been the massacre of peasants, and the burning of villages. *Valdez*, the minister of war, succeeds him. The issue of the contest is uncertain, and the state of Spain manifestly most unsettled.

**ERUPTION OF VESUVIUS.**—A Naples letter of 2d April, published in a London paper, makes this statement:—

"Vesuvius, which had for the last fortnight, given indications of an approaching eruption, burst forth last evening in all its fury. During the afternoon a storm of hail and rain, had detained the crowd of visitors at Resina, who would otherwise have been inevitably sacrificed, as the very ground round the crater, where hundreds had been walking only the evening before, was carried up into the air at the first explosion. The *Pope's* girandola, of a thousand rockets, is a joke to it. At half past nine (within less than three hours) the detonations ceased, and the fire gradually subsided.—This morning there is not even the least smoke."

# MY AUNT.

My aunt has many queer notions,—  
She never butters her bread;  
She declares that the Bulwer novels  
Are things not fit to be read;  
She thinks that to flirt is a crime,—  
And especially with youth;  
And she thinks the "Paradise Lost,"  
Is every syllable truth.

My aunt has got to her spectacles,  
Though without them she sees well enough;  
She is very well versed in politics,  
And thinks your poetry stuff.  
She imagines that all the clergymen  
Are as wise as wise can be;  
She thinks that Pope is a poet—  
But there she agrees with me.  
She dreams she can tell the mark that is left  
On my cousin's lip by a kiss;  
And of all her antic theories  
I am sure not to meddle with this.  
She might tell the track of a bird through the air,  
Or the track of a ship on the sea—  
On the viewless heart, not the visible lip,  
The stamp of a kiss will be!

[From the Boston Daily Advertiser.]

### Visit to Lady Hester Stanhope.

We translate the following history of this mysterious woman, from the notes of a Traveller, by Alphonso de Lamartine, member of the French Academy, as published in the *Courier des Etats Unis*.

Lady Hester Stanhope, the niece of Mr. Pitt, after the death of her uncle, quitted England and travelled over Europe. Young, beautiful and rich, she was every where received with the attentions and the interest, which her rank, her fortune, her intelligence and her beauty might be expected to excite. She constantly refused to unite her fate with that of her worthiest admirers, and having passed several years in the principal cities of Europe, she embarked with a numerous suite for Constantinople. The motives for this expatriation have never been known. By some it has been attributed to the death of a young English general, who was killed at this period in Spain, and for whom Lady Hester is said to retain in her heart to the present day, the most tender regret. Others suppose it to be owing merely to the taste for adventure, which belonged to the enterprising and courageous character of this young person. Whatever it may be, she set out, and passed several years in Constantinople, and finally embarked for Syria in an English vessel, taking with her the greater part of her property, and jewels of immense value, together with presents of all kinds.

The ship was overtaken by a tempest in the Gulf of Mæra, on the Coast of Carmania, opposite the Isle of Rhodes, and struck on a rock some miles from the shore. The vessel went to pieces in a few moments, and Lady Stanhope's treasures were buried in the sea; she escaped barely with her life, and was carried on a piece of the ship to a little desert island, where she passed twenty-four hours, without food and without assistance. At last some fishermen of Maronites, who were seeking for spoils of the wreck, discovered her, and conducted her to Rhodes, where she made herself known to the English Consul. This deplorable event did not cool her zeal: she went to Malta, and from there to England. She collected the wreck of her fortune, turned into money a part of her landed estates, loaded another ship with money and presents for the countries she intended to visit, and set sail. The voyage was prosperous, and she landed at Latakia, the ancient Laidonia, on the Coast of Syria, between Tripoli and Alexandria. She established herself in that neighborhood, studied Arabic, surrounded herself with people who could facilitate for her an intercourse with the different Arabian tribes, Druses, and Maronites, of the country, and prepared, (as I was then doing myself,) to make journeys of discovery into the less accessible parts of Arabia, of Mesopotamia, and of the desert.

with the last customs of our caravan, the Arabians, &c. She stopped, at Balat station, where she had united around her a thousand, and her of Palmyra, and of which

It was agreed, that any European, protected by her, might come in safety to visit the desert and the ruins of Balbec and Palmyra, provided he engaged to pay a tribute of a thousand piastres. This treaty still exists, and will be faithfully executed by the Arabs, if they receive positive proof of the protection of Lady Stanhope.

On her return from Palmyra, she escaped being carried away by a numerous band of Arabs of a different tribe, and enemies to those of Palmyra. She received timely notice from her own people, and owed her security and that of her caravan to a forced night march, and to the swiftness of her horses, who travelled over an incredible space of the desert in twenty-four hours. She returned to Damascus, where she resided some months, under the protection of the Turkish Pacha, to whom she had been strongly recommended by the Porte.

After a wandering life in all the countries of the East, Lady Hester Stanhope finally fixed herself in an almost inaccessible solitude on one of the mountains of Lebanon, near to Baalbek, the ancient Bala. The Pacha of St. John D'Acre, Abdalpakha, who

had a great respect for her and devotedness to her, granted to her the remains of a convent, and the village of Djeoun, uninhabited by the Druses. She built there several houses, surrounded by a wall of enclosure, like our fortifications of the middle ages. She made artistically a charming garden in the Turkish fashion, in which, besides a fruit and flower garden and graperies, are kiosks enriched with sculpture and arabesque paintings, water running in marble fountains, jets in the middle of the pavements of her kiosks, together with orange, fig, and citron trees in abundance. There Lady Stanhope lived for several years in a truly oriental style of luxury—surrounded by a great number of Europeans or Arabian drogomen, a numerous train of women and black slaves, and in relations of friendship and even of political alliance with the Porte, with Abdalpakha, with the Emir Bechir, sovereign of Lebanon, and especially with the Arabian Scheiks of the deserts of Syria and Bagdad.

Soon her fortune which had been still considerable, diminished from the derangement of her affairs caused by her absence from England, and she found herself reduced to thirty or forty thousand francs income, which is still sufficient in this country for the train which Lady Stanhope is obliged to keep up. Meantime those persons who had accompanied her from Europe, either died or left her, the friendship of the Arabs, which could only be maintained by presents, began to cool, her intercourse with them became less frequent, and Lady Hester fell into the complete solitude in which I found her. But she still exhibits the same heroism and the same energy, with all the constancy and resolution which have always marked her character. She never thinks for a moment of retracing her steps, she never gives a look to the world and to past times. She does not bend under neglect, or misfortune, or the prospect of old age and the forgetfulness of the living. She will remain alone where she now is, without books, without journals, without letters from Europe, without friends, without even servants, who are personally attached to her. She is surrounded merely by some negroes and some black slave children, a few Arabian peasants to take care of her garden, her horses, and to attend to her personal safety. It is generally believed in the country where she resides, and my intercourse with her inclines me to the same opinion, that the supernatural strength of her mind and of her resolution is found not merely in her own character, but also in high raised religious ideas, in which the illumination of Europe is confounded with some of the oriental forms of faith, and added to this the wonders of astrology. Whatever it may be, Lady Stanhope is a great name in the east, and a great astonishment to Europe. Finding myself so near her, I felt a desire to see her; her ideas of solitude had so much apparent sympathy with my own thoughts, that I felt very glad to ascertain how near we approached each other.

Lady Hester was apparently fifty years old.—She has features which cannot be spoiled by age. Freshness, color, grace, vanish with youth, but when beauty is in the form itself, in the purity of its lines, in dignity, majesty, in the thought of a man or woman's face, beauty may change at the different epochs of life, but it does not pass away. Such is that of Lady Stanhope—she wore on her head a white turban, on the forehead a band of purple woollen cloth, which fell on each side from the head to the shoulders, a long yellow cashmere shawl and immense Turkish robe of white silk, with floating sleeves, enveloped her whole person in its ample and majestic folds, and through only one opening on the bosom, which was left by the first turn, was made visible a second robe of unbrothered Persian stuff, which reached the throat, and was there fastened by a pearl ornament.—Turkish boots of yellow morocco, embroidered with silk, completed this beautiful oriental costume, which she wore with the freedom and grace of a person who had never from her youth worn any other.

I was conducted through an arbor of jessamines and rose laurels to the gate of her gardens. A table was laid for M. Farver and myself, we dined very quickly, and she only waited till we had risen from table, before she sent Leonard to tell me she was waiting for me; I hastened, and found her smoking a long oriental pipe—she ordered one to be brought to me. I was already accustomed to see the most beautiful and elegant women of the East smoke, and I therefore was not shocked at her grotesque and careless attitude, nor at that odoriferous smoke which escaped in light columns from the lips

of a beautiful woman, and interrupted the conversation without chilling it. We conversed a long time in this manner, and always on the favorite subject, on the only and mysterious theme of this extraordinary woman, the modern magicians, recollecting exactly the famous magicians of antiquity—the Cures of the deserts.

It appeared to me that the religious doctrines of Lady Hester were a confused, though skilful mixture of the different religions in the midst of which she has condemned herself to live. Mysterious as the Druses, of whom she alone, in the world, perhaps, knows the mystical secret—regarded as a Mussulman, and a fatalist as he is, with the Jew expecting a Messiah, and with the Christian professing the adoration of Christ, and the practice of his charitable morality. Add to that the fantastic colors and the supernatural reverses of an imagination untraced by the East, and heated by solitude and meditation, some revelations perhaps of Arabian astrologers, and you may form some idea of this sublime and fanciful compound, which it is more easy to call madness, than to analyse and understand. No, this woman is not insane. Madness, which inscribes itself in but too evident a manner in the eyes, is not written in her beautiful and direct look. Madness, which always betrays itself in aberration, which it is ever interrupting by sudden, disorderly and eccentric starts, is not to be detected in Lady Hester's conversation, which, while it is elevated, mystical and cloudy, is always sustained, connected and powerful.

If I were obliged to pronounce, I should say that it is a voluntary madness, which is studied, which knows itself, and which has its reasons for appearing mad. The powerful admiration which her genius has exercised and still continues to exercise over the Arab people, who surround the mountains, proves that this pretended madness is only an instrument. To the inhabitants of this country of prodigies, to those men of the rocks and deserts whose imagination is more dark and colored than the horizon of their own minds or seas—the word of Mahomet or of Lady Stanhope is necessary.—They want the communion with the stars, prophecies, miracles, the second sight of genius. Lady Stanhope understood this; at first by the high reach of her truly superior understanding, and then perhaps like all beings endowed with powerful intellectual faculties, she has succeeded in seducing herself, and has made herself the first convert of the symbol she has created for others. This is the effect this woman produced on me. She cannot be judged or claimed in a word, she is a statue of immense dimensions. I shall not be surprised if at some not distant day she realize a part of the destiny which she promises herself—an empire in Arabia, a throne in Jerusalem. The least political communion in the region which she inhabits might raise her even to that.

I have, said I to her, on this subject but one remark to make to you, it is that you have been too timid with events, and that you have not pushed your fortune where it might conduct you.

You speak, and she to me, like a man who still believes too much in human will, and not enough in the irresistible empire of destiny—my own strength is in that—I wait it, I do not invoke it—I am growing old—I have diminished considerably my fortune, and am now alone and abandoned on this rock of the desert, a prey to the first bold fellow who would wish to force my gates, surrounded by a band of faithless servants and ungrateful slaves, who rob me every day and sometimes threaten my life. Lately I owed my salvation only to my dagger, of which I was forced to make use to defend my bosom against the dagger of a black slave whom I had brought up. Ah well, in the midst of all these tribulations I am happy; I answer every one with the sacred word of the Mussulman, *Allah Karam*, the will of God, and I await with confidence the future, of which I have spoken to you, and of which I should wish to assure you with the certainty which you ought to have.

The name of Bonaparte was mentioned, as usual, in the conversation.

I thought, said I to her, that your fanaticism for this man, would put a barrier between us.

It is only his misfortunes and my pity for him which makes me an enthusiast in his cause, said she. It is the same with me, I replied, and so we understood each other.

I could not explain how a religious and moral woman should adhere so strongly alone without religion, and without liberty—Bonaparte was a great reformer, no doubt—he reformed the social world,

but he did not consider sufficiently the elements of which he remodelled it. He moulded his statue with the clay, and with his personal interest, instead of cutting it out of divine and moral sentiments, out of virtue and liberty.

The night passed away in this manner in conversing freely and without affectation, on the part of Lady Hester, every subject which springs from a word, and leads by chance to a conversation. I felt that no cord was wanting to that elevated and firm understanding; and that every string in this instrument gave its proper sound, full and strong, with the exception perhaps of the metaphysical string, which too great tension and solitude had falsified or raised to a too high key for mortal understandings. We parted with a sincere regret on my part, and an obliging exhibition of regret on hers.

"No, adieu," said she, "we shall often meet again in this journey, and oftener still in other journeys which you do not now project. Go to rest, and remember that you leave a friend in the solitudes of Lebanon."

She held out her hand, I laid mine on my heart after the Arabian fashion, and we departed.

#### The Parisian Sibyl.

"Whence comes it that man has such a desire to interrogate the future, such an idle anxiety to divine the veiled secrets of fortune? In every nation I discover traces of the imprudent curiosity. The Jews had their witches, the Greeks their sibyls, the Persians their magi, the Spaniards their gipsies; the Romans had their augurs, whose oracles they respected; the French have had their sorcerers, whom they frequently finished, by burning them with great ceremony.

In former days the business of sorcery was not exercised in France with impunity; and those who were given to shuffling fortunes from cards, answered for it too often with their lives. Our good ancestors were in the habit of burning without scruple all who were guilty of witchcraft; and my good ladies Villeneuve, Michel, and Le Normand, now in full career, if they had been born a century earlier, would have infallibly ended their days at the stake. But chiromancy, cartomancy and necromancy are at present fashionable sciences, and lucrative branches of trade; and sorcery, instead of leading to a funeral pile, conducts to fortune. All Paris have in succession paid their respects to the cards of Lady Villeneuve, the whites-of-eggs of Madame Michel, and the black hen of Mademoiselle Le Normand. Each of these practicers has been celebrated in her turn; but a young sorceress is now before the public who promises to surpass them all.

The temple of this new sibyl is in one of the most frequented quarters of Paris. In the morning it is open to the beauty, tender and timid, but who confides in the turn of a card; to the greedy speculator, who would know what success may attend his enterprises; to the modest and innocent girl who is anxious to discover whom she should fall in love with; to the unquiet husband whose dreams are disturbed by an ugly major of dragons, in big boots and monstrous monstrations; to the gambler who would win back at whist, what he has lost at faro. The numerous equipages ranged before the entrance, indicate the rank of the visitors.

I had heard the oracles of this modern Pythones frequently cited with great praise. Some ladies spoke to me in high terms of the vivacity of her mind, the delicacy of her questions, and especially of the promptness with which she divined what they dared not to tell her. Gentlemen had described in raptures the sweetness of her features, the elegance of her manners, and assured me that she was a most exquisite creature. These eulogies excited my curiosity; and I determined to ascertain for myself the merits and beauties of this celebrated personage.

The clock had just struck eight as I presented myself at the door of her hotel. On declaring the object of my visit, I was ushered into a little saloon furnished with the greatest simplicity, with nothing to indicate the profession of its occupant. This was a young lady about twenty-five years of age, tall, well made, expressing herself with grace, very agreeable, and various in her conversation. There was something a little malicious in her glance, and sardonic in her smile, and she jested freely upon the inconveniences of her art, and attempted to convince me of its excellence. I saw that she was not highly very well persuaded of the truth she wished to impress upon me; and I thought

that of all who came into her house, the young sibyl herself had the least faith in the infallibility of her oracles.

After having conversed with me a few moments, she ascended the sacred tripod: already the prophetic spirit had begun to move the delicate fibres of her brain, when a light rapped three times at the door of our apartment and uttered in a troubled voice—"Open; it is I." My pretty prophetess was evidently embarrassed, and I was preparing to take my leave. She prevented me—"You have the air of a gallant gentleman," she at length said to me, smiling. I bowed assent. "I am sure of it," she added, "go into this cabinet." She pushed me gently into the cabinet, shut the door upon me, and to prevent all accidents took the key with her. I consoled my captivity by making immediate use of a crevice, through which I could see every thing that was going on in the saloon.

The lady who entered was younger and more beautiful than the sibyl. Her face was a picture of innocence and candor. At length said she laughing, I have succeeded. Madame de Bassac, after having managed to inflame the jealousy of my husband, has prevailed on him to pay a visit to you; he will be here in a minute and do not forget our agreement.

The sound of a bell put an end to the conversation; the young visitor disappeared, and her friend prepared to receive De Julien.

He enters, looks about the room with nonchalance, and the better to decide upon the powers of the magician, observes that her art must reveal to her the object of his present visit. Do you doubt it? said the sibyl, in an offended tone; give yourself then the trouble to be seated; and condescend to listen to me. He took a chair. She collected herself, and arranged the cards upon the table, by way of prelude to the following dialogue.

You are married, sir; sixteen or seventeen months ago you espoused a young lady of about half your age.

What, madam?

Who has given you a thousand proofs of affection, and yet you continue to suspect her.

I confess it, said he, in utter amazement.

Queen of Diamonds—these suspicions you have imbibed from a female friend of your wife.

I admit the fact.

Seven of Spades—she has carried her effrontery so far as to advise you to apply to me.

Astonishing!

She takes up the cards, and hands them to De Julien, who cuts them, while the sibyl continues with a gravity that nothing can disturb, your wife is faithful.

Do you believe so?

I know it; but she complains of your conduct.

Of my conduct?

Your suspicions harass her.

No; she is not aware of them.

She has discovered them; you entertain at your house a very dangerous man.

And who is he?

The King of Clubs.

I do not know him, madam.

A clerk man; thirty-six years old.

It is my best friend.

He is desirous of becoming your wife's best friend, sir.

You amaze me! I am thunderstruck!

For three months past he has been trying to induce her to accept a set of diamonds that he knows you have refused to purchase.

It is true.

But she declines his offers with dignity; it is from you only that she is willing to accept any ornament that may add to her beauty.

Poor woman! exclaimed the relenting husband.

Here our sibyl again took up the cards, and divided them into three parcels, which she thus explained:

You blush at the suspicions you have entertained.

Because you assure me of the honor of my wife.

She dreams of nothing but your pleasure; at this very moment she is engaged in some scheme to advance your happiness. But, what do I see!

Eight of Clubs, and Nine of Hearts!

Is this bad fortune?

Quite the contrary; you are thinking of a present for your lady.

(A present!)

A set of diamonds.

Indeed, indeed—

In order that having me with, ungratified, she may be exposed to no temptation.

But these jewels are very dear.

Al! sir, can you too generously reward the virtue of a woman who adores you?

My wife adores me!

Eight of Hearts and Ace of Spades, Madame de Julien loves no one but her husband?

At these words, which proved the extent of the young magician's science, De Julien rose from his seat in transports; he cast upon the table a purse of indefinite weight, and ran to the jeweller to purchase the happy talisman which was to restore felicity to his household. Good fortune all that day followed his footsteps; the jeweller in an excess of good humor made him a considerable discount, and the virtue of my lady cost much less than he anticipated.

As soon as her husband was gone, Madame De Julien disappeared from her hiding place, and embraced her friend with every expression of kindness and tender gratitude.—But they immediately separated, for it was necessary that the young wife should return home to receive her spouse and her diamonds.

The sibyl liberated me, and prevented every manner of reproach on my part, by laughing herself, with a very pretty grace, at the scene of which she had made me a witness. I will not propose to you now, said she, to cast your horoscope; what you have just seen and heard, forbids the degree of confidence that is required in those who come to consult me; but I would ask you not to judge my conduct with too much severity. Men are but grown up children who pay to be deceived; and the error which flatters, is better than the truth which afflicts them. Instead of tearing away the veil that conceals the faults of De Julien's spouse, I darken them more deeply, and take the same care to render his future days happy, than another would take to make miserable. Shall I predict to the opulent banker who astonishes all Paris with his magnificence, that he will one day envy the lot of the wretch he now repulses with disdain?—

Shall I say to the father exulting in the birth of a son, this child will cover your old age with shame and bring your gray hairs with sorrow to the grave? Shall I tell Florio the flirtations of Lisette, and Lisette the infidelity of Florio? No! were I to do so, I should soon destroy my own credit; and see nothing more of this multitude of visitors who now crowd about my house to receive the approbation of their follies and the confirmation of their hopes. I have taken a surer path. I tickle the folly of every one of them. Without compromising my character, I give good fortune to the whole world. They go away from my house, quiet in heart and mind, and promise themselves to pay another visit to the little sorceress who makes them so very happy at such a trifling expense.—\*

#### PUBLIC NOTICE.

THE undersigned, Commissioners for the amelioration of the navigation of the Richelieu or Chambly River, will receive at their office, in the borough of St. Denis, until the 15th of June next, sealed propositions for the construction or erection of a Dam or Chaussee, with a Lock, to be erected about three miles above the village of St. Ours, either in Cut Stones, Common Stones, Pierre Brutes, or in Wood, according to the plans and specifications made by W. E. Hopkins, Esq., Engineer, deposited and where they can be seen at any time, in the office of Joseph Cartier, Esq., one of the said Commissioners, at St. Antoine.

All propositions addressed by the mail must be sent free of postage.

Two good securities will be required for the due execution of the aforesaid works.

Further information can be had at any time, from the undersigned, in addressing them at their respective residences, or from the said W. E. Hopkins, Esq., at Barker's Hotel, at the Chambly Basin.

Room: De St. Ours, at St. Ours.  
Joseph CARTIER, at St. Antoine.  
Jos. T. BROLET, at St. Marc.  
La. C. DUVERT, at St. Charles.  
L. F. DESCHAMBAULT, at St. Denis.

Office of the Commissioners, St. Denis, May 11, 1835. 30—4t

The above Dam and Lock are in dimensions as follows: Lock 200 feet, Chamber 50 feet wide; Dam 675 feet long, 8 feet high.

#### STEPHENSON.

Builder of a superior style of Passenger Cars for Railroad.

No. 264 Elizabeth street, near Bleeker street, New York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation.

**AMERICAN SILK HOSIERY.**—We were shown at Mr. Bird's Store, in this town, this week, some very beautiful specimens of silk hosiery for gentlemen, entirely of American fabric. They were a very neat and fine article, with every indication of durability, and are equal, if not superior to those of European manufacture. The silk was produced and manufactured at Dedham and sold at \$10 per pound. It was made into hose at the manufactory in Newburyport. We believe that small quantities of silk goods have been occasionally manufactured in different parts of our country, within a few years. Among other articles, we were shown about a year since a large variety of vesting patterns, manufactured by Mr. Golding of this town. These things all give an earnest of what may, and ultimately will, be accomplished in this country in the manufacture of silk goods.—[Bunker Hill Aurora.]

The Jingo Tree which grew on the estate of the late Gardner Greene, and of which we spoke the other day, has been safely removed to the Common, where it is to be planted. It is probably the largest tree ever transplanted in this vicinity, being 40 feet high, and the circumference, at 3½ feet from the ground, 4 feet 4 inches. The labor of transplanting it was undertaken by Mr. Sheridan, formerly gardener on the estate. The earth was carefully removed from the roots, and the tree lifted by shears and tackle from the ground, sufficiently high to pass under it a low wheeled drag. The roots were then carefully covered with matting, and the tree lowered upon the drag, on which it was easily supported in an upright position, being kept from falling by ropes attached to the top and held by men who walked along with it to its destination. Mr. Sheridan tells us that there is not the slightest doubt that it will live and flourish in its new location.—[Boston Transcript.]

We have seldom met with a more agreeable *jeu d'esprit* than the following, which we copy from the *Saturday's Magazine* for April 11:—

#### RURAL CHRONICLE.—APRIL.

**Departures.**—For the north:—Frost, Esq. and suite, amongst them we noticed Messrs. Woodcock, Fieldfare, Redwing, &c. &c.

**Arrivals.**—Early in the month, Mr. and Mrs. Swallow; family expected to follow soon. N. B. Mr. and Mrs. S. go out very little as yet.

The Messrs. Blackbird and Thrush have begun to give their annual concert for the season. Their respective ladies "are at home."

The musical foreigner of distinction, the Signor Cuckoo, whose favorite cantatas are so repeatedly encored, is said to be on the look-out for lodgings in the neighborhood: strange stories are in circulation respecting a branch of the Sparrow family.

The Widow Nightingale, to her seat in Poplar Island.

The Misses Martin for the season.

Dr. and Mrs. Rook have made great progress in their new dwelling, which is built on the old site.

The Wren family, so famous in the annals of architecture, have lately designed some edifices, which show them to be as skilful as ever in that admirable art.

#### COURT NEWS.—GAZETTE EXTRAORDINARY.

Yesterday, her Serene Highness, Queen Flora, held her first drawing-room this season, which was most numerously attended. The court opened soon after sunrise; Mr. Skylark was in attendance to announce the company.

The Misses Daisy were the earliest visitors; after which arrivals were constant.

Messrs. Bugle, Broom, Lilac, Orchis, Periwinkle, Ranunculus, Stellaria, &c. &c., all richly and tastefully attired.

The numerous family of the Anemonies paid their devoirs early. These elegantes were variously habited; some wore rich scarlet boddices, others purple and green train; the Misses A., in robes of simple white and green, almost surpassed in beauty their more splendid relatives.

The Misses Violet, on their return to the country, introduced by the Ladies Primrose; the amiable and modest appearance of the former was much noticed, the costume of each party was thought very becoming, and skilfully assorted to set off the charms of both.

The Misses Blue-Bell wore robes of azure tissue, and were much admired for the sylph-like elegance of their forms.

The beautiful Germander family, with their never-to-be-forgotten eyes of heavenly blue, attracted universal attention.

The arrival of the Rose family was anxiously expected.

The Misses Cowslip were presented; it has been the fashion to call them the "pretty rustics;" but they were most graciously received, and the delicate propriety of their dress and manners much admired.

The Lady Cardamines, costumes of the finest linen.

Mrs. Tulip, body and train of crimson and gold; this truly grand dress had a superb effect.

Messrs. Chesnut, Oak, Birch, Lime, &c., &c., sported new bright green liveries, of various shades.

Messrs. Blackthorn, Pear, Apple, &c. &c., crowded round their sovereign, eager to pay their dutiful homage; they made a magnificent show, in rich suits of white, red and green.

The company were greatly delighted with a concert of vocal music from a large party of the best performers in the neighborhood, consisting wholly of amateurs.

The Court broke up, having partaken of a few drops of a light and charming beverage, but not before the Widow Nightingale, (who had, joined the performers of the morning) had been intreated to favor the company with a song; that well-bred lady instantly complied, and poured upon the ears of her delighted auditors one of her most heart-thrilling melodies.

#### MILL-DAM FOUNDRY

ON MONDAY, June 1, at 2 o'clock, at City Hall, (unless previously disposed of at private sale,) will be sold by auction, the above well known establishment, situated one mile from Boston. The improvements consist of—

No. 1. *Boiler House*, 50 feet by 30 feet, containing all the necessary machinery for making boilers for Locomotives and other steam Engines.

No. 2. *Blacksmith's Shop*, 50 feet by 30, fitted with cranes for heavy work.

No. 3. *Locomotive House*, 54 feet by 25, used for putting together Locomotive Engines. Several of the best Engines in use in the United States have been put in this establishment.

No. 4. A three story brick building, covered with slate, 130 feet by 45, containing two water-wheels, equal to 40 horse power; Machine Shop, filled with lathes, &c.; Pattern Shop; Rolling Mill and Furnaces, capable of rolling 4 tons of iron per diem, exclusive of other work; three Trip Hammers, one of which is very large; Engine for blowing Cupola Furnaces, moved by water-wheel; one very superior 13 horse Steam Engine, which could be dispensed with; and a variety of other machinery.

No. 5. An Iron Foundry, 80 feet by 45, with a superior air Furnace and two Cupolas, Core oven, Cranes, &c. fitted for the largest work. Attached to the Foundry is a large ware-house, containing Patterns for the Castings of Hydraulic Presses, Locomotive and other Steam Engines, Lead Mill Rolls, Gearing, Shafts, Gears, Grates, &c. &c. These were made of the most durable materials, under the direction of a very scientific and practical Engineer, and are supposed to be of great value.

No. 6. A building, 65 feet by 35, containing a large stock of chimneys, and furnaces, for making Cast Steel. This building is at present used as a boarding-house, and can accommodate a large number of men.

No. 7. A range of buildings, 300 feet long by 35, containing counting room, several store rooms, a Brass Foundry, room for cleaning castings, a large loft for storing patterns, stable for two horses, &c. &c.

The above establishment being on tide water, presents greater advantages for some kinds of business than any other in the United States. Coal and iron can be carried from vessels in the harbors of Boston, to the wharf in front of the Factory, at 25 to 30 cents per ton. Some of the largest jobs of iron work have been completed at this establishment; among others, the great chain and lift pumps for freeing the Dry Dock at the Navy Yard and Charleston.

The situation for Railroad work is excellent, being in the angle formed by the crossing of the Providence and Worcester Railroads. The Locomotive "Yankee," now running on the latter road, and the "Jonathan," purchased by the State of Pennsylvania, were built at these works. With the Patterns and Machinery now in the premises, 12 Locomotives and as many tenders, besides a great quantity of cars and waggon, could be made per annum.

For terms, apply to  
THOS. J. ECKLEY, Treas' &c., Boston, or to  
ROBERT RALSTON, Jr., Philadelphia.  
Boston, April 21, 1835.

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads.

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders, addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J. S. ROGERS, KETCHUM & GROSVENOR

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept. 15-ly

#### RAILWAY IRON.

95 tons of 1 inch by 1 inch,	Flat Bars in lengths of
200 do. 1½ do.	14 to 18 feet, counter sunk
40 do. 1½ do.	holes, ends cut at an angle
800 do. 2 do.	of 45 degrees, with splicing plates and nuts to suit.
800 do. 2½ do.	

250 do. of Edge Rail of 30 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 23, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2½, 2½, 3, 3½, 4, and 4½ inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. RALSTON,  
9 South Front street, Philadelphia.  
Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. dtlmeowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by  
E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

J31 &

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,  
Mathematical Instrument Maker,  
No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.  
Baltimore, 1832.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,  
JAMES F. STABLEY, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.  
Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1833.  
For a year past I have used instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY B. CAMPBELL, Eng. Philad.  
Germantown, and Norristown, Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JUNE 6, 1835.

We learn that the election of Directors to the HUDSON AND BERKSHIRE RAILROAD COMPANY took place on the 27th of May last, and the following gentlemen were elected:

John Delafield and Gouverneur Kemble, of New-York; Robbins Kellogg, of W. Stockbridge, Mass.; James Mellen, Rufus Reed, Oliver Wigwall, Robt. A. Barnard, Samuel Anable, Elhu Gifford, John W. Edwards, Ambrose L. Jordan, Silas Sumner, &c. A. Dean.

This Board subsequently unanimously elected James Mellen their President, and J. W. Fairfield their Secretary.

**SARATOGA AND WASHINGTON RAILROAD COMPANY.**—The following gentlemen were chosen directors of this company at their annual election on Monday.

Stephen Warren, Le Grand Cannon, Richard P. Hart, John R. Cushman, Thomas J. Marvin, Augustus Corning, Lewis Benedict, John Townsend, Thomas W. Olcott, Gideon M. Davison, John Delafield, John Lorimer Graham, George B. Strong, Morgan L. Smith, Knowles Taylor.

**PENNSYLVANIA IMPROVEMENTS.**—The Lancaster Journal of last week enumerates the following works of improvement now in progress, or shortly to be undertaken, in Pennsylvania. These, when completed, will form but a part of that great

system of improved communication, which that State has had the wisdom—some may say, the temerity—to adopt and carry out, at an aggregate expense of upwards of twenty-five millions of dollars. Had these works cost twice this sum, it is quite possible—such are the wants of her great and rapidly increasing population—that the next generation would have deemed it money well laid out.—[Daily Adv.]

**Lancaster, Middletown and Harrisburg Railroad.**—Mr. Roberts, the Principal Engineer, we understand has nearly completed the surveys of this route preparatory to placing the line under contract. Active operations, it is expected, will commence very shortly.

**The Marietta Branch Railway,** forming a connection with the Columbia and Philadelphia Railway, at the Depot near Columbia. The interesting Report of the Chief Engineer, Mr. Gay, upon this important connexion with the Susquehanna, at the borough of Marietta, is published in this day's paper. By this project, the inclined plane at Columbia is entirely avoided, and one of the most favorable and beautiful upon the great river will be opened for an extensive river and inland trade. There is every prospect of the success of the un-

**Branch Railroad.**—This runs from the borough of Strasburg, to the Columbia Railroad, near the water's extent about four miles. The plan has been taken, and the road will be put under construction.

**The York and Wrightsville Railroad.**—The books to receive subscriptions to the stock of this company will be opened by the Commissioners, on Wednesday the 17th inst. at the house of Mr. Thomas York, at the United States Hotel, and at the Fountain Inn. When this road is completed, it will be one continuous line connecting the city of Washington, through Baltimore, York, Wrightsville, Columbia and Lancaster, with the city of Philadelphia.

**Chambersburg, Carlisle and Harrisburg Railway,** called the Cumberland Valley Railway.—The whole of the Stock, in this important link in the chain of a continuous

Railway from Philadelphia to Pittsburgh has been taken, and we expect to have the pleasure of calling the attention of our numerous friends who honorably fulfilled their contracts upon the Columbia and Philadelphia Railway, to the time and place of the lettings, which will soon be advertised.

**Wilmington and Susquehanna Railroad.**—Proposals will be received at the Company's office at Wilmington, until the first day of June, for the grading of the whole line; also for the Masonry, Bridges, Culverts, &c.

[From the Pittsburg Gazette of 25th May.]  
**IMPROVEMENT OF THE ALLEGHENY RIVER.**—We have had the pleasure, within a few days past, of a long conference with Mr. James G. King, of New-York, President of the New-York and Erie Railroad Company, and Mr. Samuel B. Ruggles, one of the Directors, and subsequently with Mr. P. G. Stuyvesant, another Director of the same Company. From each of those gentlemen, we received the fullest and most satisfactory assurances that a large portion of the Railroad will be placed under contract this fall, and that the work will be prosecuted with the utmost energy to completion.

We were, however, particularly gratified to learn that their attention was directed to the connection with the Allegheny, at Olean, or Warren, and that they were fully aware of the importance of the improvement of that river. We had noticed, for some time past, that the attention of the New Yorkers was turning towards that route, but had no expectation of finding them so fully informed in relation to that important river, and so ardently desirous of its improvement.

Finding them exceedingly anxious that some initiatory steps should be taken, in order to devise some plan of operation, it was suggested, after consultation with several friends in Pittsburg, who take an interest in the work, that a convention of delegates from the counties interested in that improvement, should be held at Kittanning, on Thursday, the 18th of June. The object of such a convention would be to collect all the information which is at present attainable, as to the character of the river, the best mode of improving it, the probable expense, and also, to decide whether application should be made to Congress or to the Legislature, and if to the latter, whether the work to be done by the State, or for the incorporation of a company.

We shall send a copy of this paper to the seat of justice of each county along the river, from Pittsburg to Olean, and ask that we should be immediately informed whether delegates will be appointed. We believe that now is the very time to strike in this matter. New Yorkers are at length fully awake to the importance, and indeed to the indispensableness, of this work.

*On the Location of Railroad Curvatures; being an Investigation of all the Principal Formulas which are required for Field Operations, in laying Curves and Tangent Lines, to pass through Given Points.*  
By J. S. VAN DE GRAAFF. [For the American Railroad Journal.]

[Continued from page 319, vol. m.]

24. When the given curve ADF, (see fig. art. 23,) has been actually traced in the field, the co-ordinates  $x, y$ , have to be computed by means of (VII.) in order to obtain the distance FR, as proposed in the last article. In such a case, if the two moduli of curvatures  $T$  and  $T'$  be equal to each other, the distance FR and the angle P will be more conveniently had by means of a direct formula in terms of  $n, m, T$ , and  $\alpha$ , without first computing the values of the co-ordinates  $x, y$ , and  $x', y'$ . For when (XXIII.) is developed, agreeably to the common principles of algebra, the result is,  $w = (x^2 + y^2 + x'^2 + y'^2 - 2xx' - 2yy' - 2\alpha \cdot x - x' + \alpha^2)^{\frac{1}{2}}$ ; and by substituting in this equation for  $x, y$ , and  $x', y'$ , their values obtained from (VII.), upon the supposition that  $T = T'$ ; suppressing the quantities which cancel each other, and reducing the result, agreeably to the principles of analytical trigonometry; the following formula will be then obtained:

$$w = \left\{ \frac{1 - \cos(2nT - 2mT)}{1 - \cos 2T} - \alpha^2 \right\}^{\frac{1}{2}} \quad (\text{XXV.})^*$$

Thus, an expression for the value of  $w$  has been obtained, which will be quite convenient for use in the field, with the table of natural sines and cosines, and the table of the squares and square roots of numbers, subjoined to this volume. But the values of the co-ordinates  $x, y$ , and  $x', y'$ , not being here computed, a new formula will be required for determining the angle P. For this purpose it will be only necessary to substitute in  $\cos. P = \frac{x' - x - \alpha}{w}$ ,

the values of  $x'$  and  $x$ , as obtained from (VII.) The following expression will be then obtained:

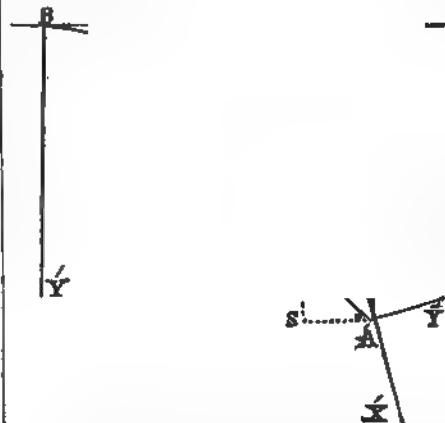

$$\cos. P = \frac{\frac{\sin 2mT - \sin 2nT}{2 \sin T} - \alpha}{w} \quad (\text{XXVI.})$$

A formula expressing the value of  $\cos. P$ , has been here selected in preference to one for the value of  $\sin. P$ , for the obvious reason that the principal term in the numerator of (XXVI.) is had, by simply dividing by 2, one of the quantities in (XXV.), whose value will always be previously known from the computation of  $w$ . But with regard to the sign of  $\sin. P$ , it may be observed that, in the case here under consideration,  $\sin. P$  will always be positive when  $n - m$  is positive; and vice versa.

If in (XXV.), it be supposed that  $n = m$ , the result is,  $w = \alpha$ . That is, the distance between the two curves, in a direction parallel to the common tangent at the origins, is always the same constant quantity  $= \alpha$ . See art. 11.

25. Suppose ADF to represent a given curve, and BMR another proposed curve laid upon the same tangent line AX, and let  $\alpha$  denote the given distance AB, between their

origins. Take T and T', to represent the given moduli of curvatures; and let each curve pass into a tangent, FA', and RB', at the extremity of the  $n$ th and  $m$ th chain respectively. Let the number of chains contained in each tangent be denoted by  $v$  and  $v'$  respectively. It is then required to determine the distance A'B', between the extremities of those two tangents. And taking A'X', A'Y', for a system of rectangular co-ordinate axes, coinciding with the given origin A', and tangent line A'F, it is proposed to investigate expressions for the values of the co-ordinates A'H', H'B', of the point B'.

The first thing which will be required, in the present inquiry, is the value of each of the co-ordinates AX, XA', and BP, PB', of the two points A' and B', estimated from the primitive axes AX, AY, and BX, BY'. Let those co-ordinates be represented by X, Y, and X', Y', respectively. The following equations will then evidently exist,  $\begin{cases} X = x + FH \\ Y = y + A'H \end{cases}$ ; but by (IV.),  $\angle HFA' = 2nT$ , and therefore by the principles of trigonometry,  $FH = v \cos. 2nT$ ,  $A'H = v \sin. 2nT$ . The following formulas will therefore be the result:

$$\begin{aligned} X &= x + v \cos. 2nT \\ Y &= y + v \sin. 2nT. \end{aligned} \quad (\text{XXVII.})$$

And in like manner the following similar equations may be obtained:

$$\begin{aligned} X' &= x' + v' \cos. 2mT' \\ Y' &= y' + v' \sin. 2mT'. \end{aligned} \quad (\text{XXVIII.})$$

Now, taking W to denote the required distance A'B', its value will obviously be expressed in the following manner:

$$W = \left\{ X + \alpha - Y' \right\}^2 + Y - Y'^2 \quad (\text{XXIX.})$$

The theorems (XXVII.) will frequently find an application in the field, as a means of investigating particular cases which will occur, where tangents are concerned; and in every case in which the line A'B' is required to be known, its value cannot be computed by any other method with more ease than by (XXIX.), a table of the squares and square roots of numbers being at hand.

It will sometimes happen that the point B' is required to be the origin of a new curve, whose modulus of curvature must be found by means of data furnished from another curve previously computed, or actually traced, from the origin A', and axes A'X', and A'Y'; and in such a case, the co-ordinates A'H', H'B', furnish the most convenient data for computing the new curvature, which was fully explained in article 22.

Put,  $\alpha' = A'H'$ , and  $\beta' = H'B'$ ; and for the sake of convenient notation, take  $k = X + \alpha - X' = SA'$ , and  $h = Y - Y' = SB'$ . It is obvious that,  $\angle SA'H' = 2nT$ , and  $\angle SB'H' = 180^\circ - 2mT'$ ; and there-

fore, agreeably to a well known theorem in plane trigonometry,\* a diagonal from S to H will be expressed either by

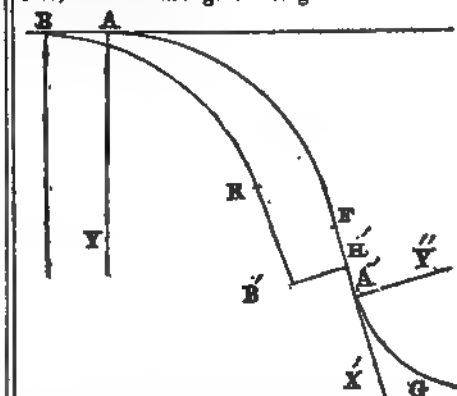

$$k^2 + \alpha'^2 - 2k\alpha' \cos. 2nT^{\frac{1}{2}},$$

or by  $h^2 + \beta'^2 + 2h\beta' \cos. 2mT'^{\frac{1}{2}}$ ; these two quantities are therefore equal, and consequently recollecting that  $\alpha'^2 + \beta'^2 = h^2 + k^2$ , the result will be  $\alpha'^2 - h^2 = k\alpha' \cos. 2nT + h \cdot (h^2 + k^2 - \alpha'^2)^{\frac{1}{2}} \cos. 2mT'$ ; that is,  $\frac{\alpha'^2 - h^2}{\alpha' - h^2} + k^2 \alpha'^2 \cos. 2nT - 2k\alpha' \cdot (\alpha'^2 - h^2) \cos. 2nT = h^2 \cdot (h^2 + k^2 - \alpha'^2) \cos. 2mT' = h^2 k^2 \cos. 2nT - h^2 \cdot (\alpha'^2 - h^2) \cos. 2mT'$ ; or,  $\frac{\alpha'^2 - h^2}{\alpha' - h^2} - 2k\alpha' \cdot (\alpha'^2 - h^2) \cos. 2nT = -h^2 \cdot (\alpha'^2 - h^2) \cos. 2mT' - h^2 \cdot (\alpha'^2 - h^2) \cos. 2mT'$ ; that is,  $\alpha'^2 - h^2 - 2k\alpha' \cos. 2nT = -h^2 \cdot \cos. 2mT' - h^2 \cdot \cos. 2mT'$ ; and this equation is now easily reduced, by the method of quadratics, to the form,  $\alpha' - k \cos. 2nT = h \sin. 2mT'$ . By pursuing the same method with regard to  $\beta'$ , a similar result will be obtained; and thus the formulas which it was proposed to investigate are the following:

$$\begin{aligned} \alpha' &= k \cos. 2nT + h \sin. 2mT' \\ \beta' &= k \sin. 2nT - h \cos. 2mT' \end{aligned} \quad (\text{XXX.})$$

It is easy to see that the expressions just obtained might have been deduced with more facility immediately from (XXI.); but a special investigation was considered preferable. The following case may be assumed, in order to show a practical application of (XXX.).

Example. Let AX be a given tangent line, and A the given origin of a curve.

From the origin A, and parallel to the axes AX, AY, let a system of rectangular lines be traced to a certain designated point F, selected in such a manner as to give an integer number of chains in the curve AF, agreeably to the method explained in art. 17; and let the values of T,  $n, x$ , and  $y$ , as deduced therefrom, be,  $T = 2^\circ 3'$ ,  $n = 18$  chains,  $x = 13.40$  chains, and  $y = 10.08$  chains. From the point F suppose a tangent FA' to be laid 9 chains, agreeably to the method explained in art. 16; and from the point A', as a new origin, and parallel to the rectangular axes A'X', A'Y', let a second system of rectangular lines be traced, terminating in a certain designated point G, and let the resulting equations give  $\begin{cases} x = 10 \\ y = 10 \end{cases}$  chains, agreeably to art. 16. Now, having computed the modulus of curvature of A'G, and examined the direction

\* This theorem is sometimes wanted in the field, and it may therefore be convenient to have it expressed here, in the usual form. Take  $a$ , and  $b$ , to denote any two sides of a plane triangle, and let  $X$  represent the contained angle, and  $x$  the opposite side. Then

$$x^2 = a^2 + b^2 - 2ab \cos. X$$

at G, suppose it be found, in consequence of the particular situation of the ground from A' to G, to be advisable to change the origin of the curve AF to a point B, 4 chains back upon the tangent line AX, and from thence to lay a curve BR, from the same modulus of curvature, for a distance of 15 chains to the point R; and then a tangent RB' for a distance of 12 chains to the point B'. It is then proposed to know what modulus of curvature will trace a curve from the tangent line RB', and from the origin B', passing through the same designated point G.

In such a case as the present, the co-ordinates  $x'$ ,  $y'$ ,  $X'$ ,  $Y'$ , and  $X$ ,  $Y$ , of the points R, B', and A', respectively, will most generally have been already computed in making a proper selection of the points R and B', before any calculation is wanted with regard to the modulus of curvature of the required curve from B' to G. But to show an example in figures, of the manner of obtaining those co-ordinates, the given data at present are,  $T = 2^\circ 3'$ ,  $n = 18$ ,  $x = 13.40$ ,  $y = 10.08$ ,  $v = 9$ ,  $T' = 2^\circ 3'$ ,  $m = 15$ , and  $v' = 12$ . Hence,  $2nT = 73^\circ 48'$ ,  $2mT' = 61^\circ 30'$ ; and by (VII.),  $x' = \frac{\sin. 61^\circ 30'}{2 \sin. 2^\circ 3'} =$

$$\frac{.87882}{.07154} = 12.28, y' = \frac{1 - \cos. 61^\circ 30'}{2 \sin. 2^\circ 3'} = \frac{.53284}{.07154} = 7.31; \text{ and by (XXVII.), } X = 13.40;$$

$$+ 9 \times \cos. 73^\circ 48' = 13.40 + 9 \times .279 = 13.40 + 2.51 = 15.91, Y = 10.08 + 9 \times \sin. 73^\circ 48' = 10.08 + 9 \times .960 = 10.08 + 8.64 = 18.72; \text{ and by (XXVIII.), } X' = 12.28 + 12 \times \cos. 61^\circ 30' = 12.28 + 12 \times .477 = 12.28 + 5.73 = 18.01, Y' = 7.31 + 12 \times \sin. 61^\circ 30' = 7.31 + 12 \times .879 = 7.31 + 10.54 = 17.85. \text{ We now have } k = 15.91 + 4.00 - 18.01 = 1.90, h = 18.72 - 17.85 = 0.87; \text{ and by (XXX.), } \alpha' = 1.9 \times .279 + .87 \times .960 = .53 + .84 = 1.37, \beta' = 1.9 \times .960 - .87 \times .279 = 1.82 - .24 = 1.58, \text{ which are therefore the values of the co-ordinates of the new origin B'; and thus the required modulus of curvature is readily found, by means of (XXII.), to be } = 1^\circ 56'.$$

It will sometimes be very convenient in the field, to determine by measurement the values of the co-ordinates, A' H', H' B', of the new origin B', after the new line BRB' has been traced up to the point B'.

[From the Journal of the Franklin Institute.]

#### Notice of the Sandy and Beaver and the Mahoning Canal.

Two companies have been chartered by the Legislatures of Ohio and Pennsylvania, to construct canals to connect the western termination of Pennsylvania with the Ohio and Erie canal. A charter for the Mahoning, or northern route, was first obtained; subsequently, a charter for the southern, or Sandy and Beaver, route, was granted.

The Sandy and Beaver route commences at the mouth of the Big Beaver, twenty-eight miles below Pittsburg, and continues down the north flats of the Ohio river, to Little Beaver creek; thence it occupies the valley of that stream, till it reaches the town of New-Lisbon, a short distance north of which it ascends, by a narrow ravine, to the dividing ridge between the waters of the Beaver and Sandy; after crossing which, it continues along the valley of the Sandy, and gradually descends to its mouth, near

which it intersects with the Ohio and Erie canal, at Bolivar.

The route is ninety miles in extent, and is located through an extremely rich and fertile country; the summit occupies the dividing ridge between New-Lisbon and a point west of the town of Hanover, a distance of fourteen miles; it receives the drainage of eighty square miles of country, and is to be supplied with water from Cold Run, Brush Run, and west fork of Little Beaver creek, Sandy creek, Holland's creek, Mendenhall's run, and Davis' branch; in addition to which, the head waters of the Mahoning can be conducted into it by means of a short feeder. These streams, at their minimum, afford sufficient water for the transit of seventeen boats per day, and, during nine months of the year, an average flow of 2,570 cubic feet of water per minute; an amount adequate to accommodate a trade of 295 boats per day: in addition to this, it is proposed to erect reservoirs, from time to time, as the business may require. Many eligible sites for this purpose are to be found contiguous to the line, four of which have been surveyed, and found to have capacity to contain 280,000,000 cubic feet of water, and would inundate 726 acres of land.

The work is to be constructed of the same dimensions as the Pennsylvania and Ohio canals; the locks, aqueducts, and bridge abutments, are to be formed of sand-stone, and are intended to be of the most permanent character; the country through which the route is located affords materials for the construction of the work, such as stone, timber, and hydraulic lime, of the best description, and in the greatest abundance; the cost of the whole work, including reservoirs, is estimated at \$1,289,000.

The Governor of Ohio, in his last annual message, mentions the Sandy and Beaver canal in the following favorable manner: "Viewing a communication between the Pennsylvania and Ohio canals to be a subject of great interest, it is with peculiar satisfaction I communicate to you the intelligence, that the Sandy and Beaver canal company was organized during the last summer, under the liberal provision of the original charter, and the munificent grant of the legislature, in an amendatory act of the last session." "By the report of two able and experienced engineers, all doubts have been removed from the public mind, as to the supply of water on the summit, and is conclusive as to the question of an abundant supply of water for all the demands of an extensive commerce." "Such a connexion has long been a desideratum to the people of the interior and southern parts of Ohio, as it will open to them a new and short route to the eastern markets for their abundant produce, and will enable eastern and western merchants to transport goods from the east at a much earlier period of the spring than by the New-York canal."

The Mahoning, or northern route, commences at the village of Akron, on the Ohio and Erie canal, and from thence extends, in an easterly direction, to the Little Cuyahoga, at Middlebury; "from which it pursues a north-easterly course, until it approaches near the main Cuyahoga, in the township of Stow; thence continuing the same general direction along the south and south-east bank of that river, until it passes the village of Franklin, it enters the valley of the Breakneck creek, and passing up that valley in an easterly course, it crosses the summit between the waters of the Cuyahoga and Mahoning branch of the Big Beaver, near the village of Ravenna. The line then descends rapidly into the valley of the

west branch of the Mahoning, crosses that stream near its south-westerly bend, continues along its north bank, recrossing that branch, and also the south, or main branch, a mile above the junction of those streams; then leaving the river, the line pursues an easterly course, again approaching the river opposite the village of Warren," and then continues along the valley of the river, in a south-easterly direction, to the Big Beaver; thence it follows the valley of the Big Beaver, and connects with the Ohio at the town of Beaver. The whole distance from Akron to the Ohio, by this route, is about one hundred and twelve miles.

The canal commissioners of the state of Ohio, in their report on this route, propose to supply the summit level with water by the following means.

1st. By a feeder from Breakneck creek. This stream, they state, may be introduced by a feeder three miles and six chains in length, and is sufficient for the supply of the summit level, and the contiguous levels, in ordinary seasons, during more than half the year. In the dryest seasons, when the flow of water is reduced to the least quantity, it yields about 240 cubic feet per minute.

2d. By forming reservoirs of four lakes, or ponds, situated near the summit. These bodies of water, Muddy Pond, Sandy Pond, Brady's Lake, and Lake Pippin, may, they state, be converted into valuable and convenient reservoirs, for the supply of the summit, and the adjacent levels; the two former will contain an area of about 240 acres. Water to the depth of twenty feet, or even more, may be accumulated in these ponds, and conducted into the canal, by means of a feeder, seventy-eight chains in length. A depth of eight or ten feet of water on the area of Brady's Lake, and Lake Pippin, may be made available to supply the canal in dry seasons.

It is computed that 325,000,000 cubic feet of water may be reserved for use in these reservoirs.

It will be perceived by the foregoing description—deduced from the reports of Maj. Douglass, Col. Kearney, E. H. Gill, H. Hage, and Col. Dodge, the engineers that examined the routes—that the summit of each canal has to rely on reservoirs, during a period of drought, for a supply of water. By an examination of their respective charters, it will be found that the stockholders of the northern, or Mahoning route, are permitted to receive but ten per cent. on the cost of the work in tolls, while the Sandy and Beaver canal company are allowed twenty; in addition to which, it has received from the Legislature of Ohio the following very liberal grant, which alone, in a very few years, will much more than repay the cost of the work.

"That when the canal authorised to be constructed by the act, entitled an act to incorporate the Sandy and Beaver canal company, shall have been completed twenty miles from the Ohio canal, said company shall be entitled to collect and receive the tolls accruing on the Ohio canal, on all freight and passengers that may be transported thereon, and which have been transported not less than twenty miles on said Sandy and Beaver canal, to the Ohio canal; and to receive the toll on all freight and passengers that may be transported thereon, and discharged and landed in said Sandy and Beaver canal, at any point not less than twenty miles from the Ohio canal, for the term of seven years from and after the completion of the twenty miles of canal aforesaid."

Viewing the two routes in point of accommodation to the trade of the west and south-west, embracing the states of Kentucky, Indiana, Illinois, Missouri, and the most fertile portion of Ohio, it will be observed that, by the Sandy and Beaver route, the distance to Pittsburg, or Philadelphia, is sixty-five miles less than by the Mahoning, or northern route.

The western termination of the Sandy and Beaver canal is in 40° 36', north latitude; Pittsburg, 40° 28'; and Philadelphia, in 39° 57'. Hence, it will be perceived that the three places are nearly in a direct line. These facts portray, in the strongest light, the merits and advantages possessed by this route over any other, and that it is the most direct and desirable continuation of the Pennsylvania canal. From the western termination of the Sandy and Beaver canal, at Bolivar, the distance by the Ohio canal, Lake Erie, the New-York canal, and Hudson river, to the city of New-York, is 780 miles; and by the Sandy and Beaver route, and Pennsylvania improvements, to Philadelphia, 511; making a difference between these two communications to the sea-board, of 269 miles. In addition to this very decided advantage in distance in favor of the Pennsylvania and Ohio communication, is to be added, safety, economy, and despatch, and the long periods in spring and autumn which it could be used, when the lake route would be obstructed by ice, or hazardous, as is often the case, by storms.

The immense commerce that the Sandy and Beaver connexion will secure to our market cannot at present be approached, even by conjecture. If we view the vast extent of rapidly improving country, where cities and towns are springing up as if by magic, two-thirds of the rich products of which must seek our market channel, some distant idea of the benefits our present improvements, and the city of are destined to derive from it.

As both the northern and southern route have to receive a supply of water, during a dry period, from reservoirs, the following statement may prove interesting.

Philadelphia, Dec. 29, 1834.

Sir: In conformity with your request, I hand you the following statement, descriptive of the merits of the summit of the Sandy and Beaver canal, compared with the Licking summit of the Ohio canal; the latter, you will perceive from the annexed letter from the present acting canal commissioner of the state of Ohio, Leander Ransom, Esq., the general accuracy of which I can vouch for, from my own personal observation, has thus far been, in a measure, entirely supplied with water by a reservoir; this reservoir covers an extent of about 2,400 acres, and, when full, has a depth of six feet above the plane of the water in the canal, and is said to contain 570,000,000 cubic feet of water; it is located on a stream which, during ordinary seasons, affords a flow of fifty cubic feet per minute, but which, during the latter part of the last summer, was entirely dry. The reservoir receives the drainage of from thirty to forty square miles of country, and, during all portions of the year, it alone has to supply near thirty miles of the summit, and dependent levels, with water, and during the dry season, about forty-four miles. At the period of my visit to the reservoir, which was during the driest part of the past season, there was a flow from it into the canal of 1,320 cubic feet per minute, which, at that time, was the only supply received by

the summit, and its then dependent levels. The average number of boats then passing, was eight per day; to convey which across the summit required at least an expense of twelve locks full of water per day, equal to 112 cubic feet per minute; if to this sum is added one cubic foot per minute for leakage, and one cubic foot per minute for evaporation, there will be left for the reservoir, 1,117 cubic feet per minute.

This, though I shall, in the following calculations, assume it as datum, is by far too liberal an allowance, because, from its nature and observation, made by me, I found that the upper level, in miles in extent, and through a similar character, to the summit of the Sandy and Beaver canal, but minute were lost by evaporation, or, or thirteen cubic feet per minute.

The natural flow of water into of the Sandy and Beaver canal, during the driest period of the year, and measured during the past extremely dry season, is 558 cubic feet per minute, (though for nine months of the year it will average 2,570 cubic feet per minute;) the extent of line dependent on this supply is twenty miles, but seven of which, from the peculiarly favorable formation of the soil, and its wet and springy nature, can possibly require any allowance for leakage and evaporation. If, on this seven miles, an allowance for leakage and evaporation of twenty-five cubic feet per mile per minute is made, amounting in the aggregate to 175 feet per minute, there will still be left 383 cubic feet per minute for leakage at the locks, and the purposes of navigation; sufficient to accommodate a trade of thirty-eight boats per day, (the locks having a lift of six feet,) during the dry season, without any aid whatever from reservoirs.

No section of country is, perhaps, more favorably formed, in point of soil and topography, for the construction of numerous and large reservoirs, than that through which is located there capacity of water per minute, the result of my personal observation, has thus far been, in a measure, entirely supplied with water by a reservoir; this reservoir covers an extent of about 2,400 acres, and, when full, has a depth of six feet above the plane of the water in the canal, and is said to contain 570,000,000 cubic feet of water; it is located on a stream which, during ordinary seasons, affords a flow of fifty cubic feet per minute, but which, during the latter part of the last summer, was entirely dry. The reservoir receives the drainage of from thirty to forty square miles of country, and, during all portions of the year, it alone has to supply near thirty miles of the summit, and dependent levels, with water, and during the dry season, about forty-four miles. At the period of my visit to the reservoir, which was during the driest part of the past season, there was a flow from it into the canal of 1,320 cubic feet per minute, which, at that time, was the only supply received by

the Licking summit of the Ohio canal, and that of your proposed canal, it will be observed the former has an extent of forty-four miles, which is entirely dependent on the reservoir for water during the dry season; that the natural flow of water into that reservoir is but fifty cubic feet per minute, the drainage about thirty-five square miles, and the maximum depth of the reservoir is but six feet; while the latter

has an extent of but twenty miles, to meet the demands of which there is a natural flow, at the driest periods of the year, of 550 cubic feet per minute; in addition to which, numerous reservoirs may be formed as required, varying from ten to thirty feet in depth, and having a surface of eighty square miles, to supply them with water.

The very favorable result afforded by the Licking reservoir may be fully anticipated from the proposed works of a similar character on the summit of the Sandy and Beaver canal; the soil and country are alike, and their proximity to each other renders each alike subject to the effect of the same changes of climate. I cannot think any other evidence than a comparison requisite to satisfy an unbiased mind, that the supply of water that can be obtained on your proposed canal route, is far more than adequate to meet the demands that may be made on it.

But other evidence, if requisite, can be added in favor of the firm reliance that can be placed in reservoirs; if we look to France, there we find the Langue-doc canal, supplied in a great measure from a reservoir; if we refer to England, we find the Rochdale, the Huddersfield, the Nottingham, the Gakham, the Oxford, the Dudley, the Stourbridge, and the Grand Trunk canals, the summits of most of which are entirely supplied with water by reservoirs. In Scotland, they have been found of immense advantage. In our own country, we have, in addition to the Licking and Portage summits of the Ohio canal, which are supplied by reservoirs, the summit of the Chesapeake and Delaware canal, which is, of itself, a large reservoir, and receives but a small portion of constant running water, and the summit of the Union canal. The Schuylkill Navigation Company has, during the late dry season, received great assistance from the reservoir lately erected at the head of their works.

Very respectfully, yours,

E. H. GILL, Civil Engineer.

B. W. BAKWELL, Esq.,

One of the Directors of the Sandy and Beaver Canal.

Extract from a letter from Leander Ransom, Esq., Acting Ohio Canal Commissioner, in relation to the Licking Summit and Reservoir.

"The extent of country drained by the reservoir is between thirty and forty square miles.

"The extent of line supplied in part to the westward of the reservoir is about thirty miles in the driest part of the season; however, the water received from other sources is very inconsiderable, much depending on the duration of the drought. In the driest part of the season, nearly thirty miles to the westward, and fourteen north-east, in all forty-four miles, are supplied from the reservoir.

"The reservoir is supposed to contain, when filled to six feet above top water line of the canal, about 570,000,000 cubic feet of water, about 570,000,000 of which is available, and to cover about 2,400 acres.

"Something of an idea of the expenditure of water from the reservoir for a part of this season, may be formed from the following observations, to wit: On the 25th of June, the water in the reservoir was 4 feet 6 inches above top water line in the canal; July 13th, 4 feet 2; August 27th, 3 feet 8; September 24th, 3 feet. No rain having fallen from July 4th, to September 24th."

Mr. Ransom states that the reservoir

could have been filled much more, but it was not considered necessary; and the superintendent informed me that it could have been filled in July, had it been deemed requisite.  
E. H. G.

Hamilton, June 1st, 1853.

To the Editor of the Railroad Journal:

Sir: In your last number, in a letter from E. F. Johnson, Esq., I observed a misstatement in reference to the grade of the Mohawk and Hudson Railroad, which I beg leave to correct.

Mr. Johnson states that the greatest inclination between the inclined planes is 37½ feet per mile, for 1½ miles.

The greatest inclination between the above mentioned points is 1 in 225, or nearly 43½ feet per mile, for nearly 2½ miles.

Very respectfully,  
W. J. McA.

Our correspondent W. J. McA., will find, by a reference to No. 21 of this Journal, that Mr. Johnson detected, and explained, the error referred to in the above letter.

[From the Albany Argus.]

WEIGH LOCKS ON THE CANALS.—We have been furnished with the following statement, which we publish for the information of those who are interested in the navigation of the canals.

For the purpose of testing the accuracy of the weigh locks on the canals, and their agreement with each other, an arrangement was made by the collector and weigh-master at Rochester, with Capt. T. C. Whitney, of the canal boat Richmond, to have a cargo weighed into the boat by ordinary scales, and then to have the boat and cargo weighed at the several weigh locks from Rochester to Albany.

The light weight of the boat was taken at the Rochester lock, and was found to be 43,050 lbs.—The boat was then loaded with 250 barrels of flour, which were weighed in lots of 10, 20 and 25 barrel as they were put into the boat, by the ordinary merchant's scale; and the accuracy of the weigh lock was tested when each lot was put on board. The 250 barrels weighed by the merchant's scale,

	54,050 lbs.
And by the weigh lock,	53,800 "
The weigh lock making the cargo less	—
than the ordinary scale by	250 "

At the Syracuse lock, the cargo weighed 54,950, being 763 pounds more than the weight of the merchant's scale.

At the Utica lock, the cargo weighed 55,100, being 1012 pounds more than the weight by the merchant's scale.

At the West Troy lock, the cargo weighed 54,250 pounds, being 152 pounds more than the weight by the merchant's scale.

At the lock at Albany, the cargo weighed 53,900 lbs., being 158 lbs. less than the weight by the merchant's scale.

After the cargo was unladen, the boat was taken into the lock at Albany and the light weight again ascertained, which was found to be 44,900 pounds being less by 150 lbs. than the light weight as ascertained at Rochester.

The weight of boat and cargo at Albany, therefore stands thus:

Boat and cargo,	98,900 lbs.
Light weight of boat at Albany,	44,900 "

Weight of cargo,	54,050 "
Weight of cargo by merchant's scales,	54,050 "
Difference, 36 lbs. less at the Albany weigh lock.	

The boat Richmond left Rochester on the morning of the 20th May, passed Syracuse on the 21st Utica on the 22d, and West Troy on the 24th.

It is stated that the boat was wet when weighed at Syracuse and Utica. It is evident, however from the test made in 1833, as well as the one now made, that the weigh lock at Utica will over run about 1000 lbs. in 50 tons.—In 1833 it overran 1110 lbs. on a boat and cargo of 97,150 pounds.

The weigh locks were tested in 1833 with a cargo of 250 barrels of flour. The following show the result of the tests in both years, comparing the weight of the cargo at each lock, with the weight as ascertained by the merchant's scales, viz:

*Apparatus for Making Ship's Biscuits.* By THOMAS TASSELL GRANT, Esq., of Weovil, near Portsmouth.\*

The advantages claimed for the new, over the old method of preparing ship's biscuit, are, superior economy and expedition, greater cleanliness in the process, and a better quality in the manufactured article.

The mode of making ship's biscuit, as practised in the king's bakehouse at Portsmouth, was as follows:

Five men were appointed to the service of each of the nine ovens, being forty-five in the whole.

The first of these was the idelman, whose business was to mix the meal and water in due proportions, and to incorporate the materials as accurately as possible by kneading the dough for half an hour, with his naked arms plunged into it up to the elbows, and finishing the operation by jumping into the trough and treading the dough with his feet. Hence it passed to the brakeman, who completed the kneading by means of a lever, on which he pressed with his whole weight, this part of the process being called riding down the dough.

It then passed into the hands of the furner, who first divided the dough into lumps somewhat bigger than an egg, and passed them on to his mate, who pressed and moulded each by hand into the form of a biscuit, and finished by pricking them with an iron instrument, to prevent blisters from rising in the dough during baking.

The biscuits being thus formed, were supplied in succession to the pitcher, who threw each on the peel of the furner as soon as he had deposited the previous one in its proper place in the oven. Each oven was capable of holding 450 biscuits, weighing together one hundred weight; and two charges, that is, 900 biscuits, were baked in an hour.

The above-described process, besides the general slovenliness of it, was liable to the two following disadvantages:

It was not possible for the idelman and brakeman, with all their care, to effect a perfect and uniform mixture of the flour with the water; the consequence of which was, that the wetter portions detained some of the water till it was boiling hot, and in that state re-acted on the starch of the flour, so as to give the biscuit, when dry, a glossy fracture and almost stony hardness.

Neither could the furner divide the mass of dough into lumps of perfectly equal size, in consequence of which, the biscuits being of various thickness, the thinner ones were scorched in the baking, and the thicker ones were under-baked, so that they soon became mouldy in the close warm air of a ship's bread-room.

In Mr. Grant's apparatus, the greater part of the labor is performed by steam power; the nine ovens are heated by one continuous fire-place, the flame of which is admitted by means of a register into each oven as soon as the previous charge

has been withdrawn, and in five minutes brings it to a sufficient heat. It takes fourteen or fifteen minutes to bake each charge, so that three charges can be worked off in one hour, being an advantage in point of expedition of one-half more than by the old method.

This apparatus was first erected at Weovil, near Portsmouth, in the year 1832, under the immediate superintendence of Sir John Rennie, and has continued at work successfully up to the present time. It has since been adopted, with certain modifications, at the bakehouse of Messrs. Fraser and Hullah, of Wapping, who have kindly permitted the Society to inspect it, and to take the requisite observations for preparing the annexed sketches and description, by which it is hoped that it will be rendered generally intelligible.

The first machine is the mixer, of which fig. 1 is an end elevation, fig. 2 a transverse section, and fig. 3 a longitudinal section. It consists of a cast-iron case, *a, a*, nearly four feet long and three feet in diameter, enlarged, however, at the upper part, a few inches beyond the circular form, as shown by the upper dotted line in fig. 2. The radial lines in fig. 1 are merely ribs to strengthen the end of the case. A flap or door, *b, b*, the whole length of the case, opens upwards, to enable the workmen at any time to inspect the interior; and another larger flap or door, *c, c*, opens downwards, for the purpose of removing the contents of the case. This latter door is opened and shut by means of a quadrant-rack, *d*,

Fig. 1.

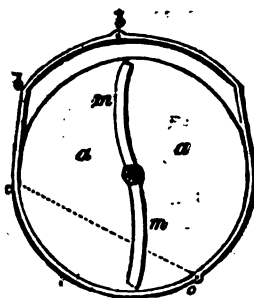

Fig. 2.

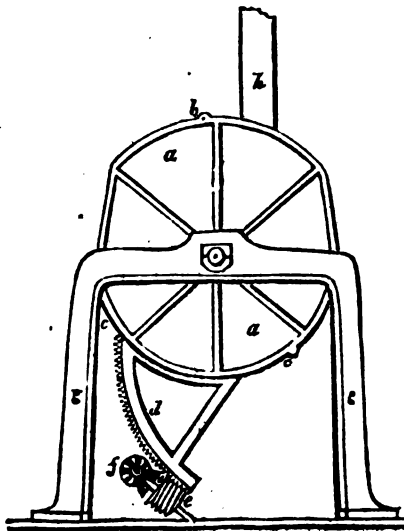

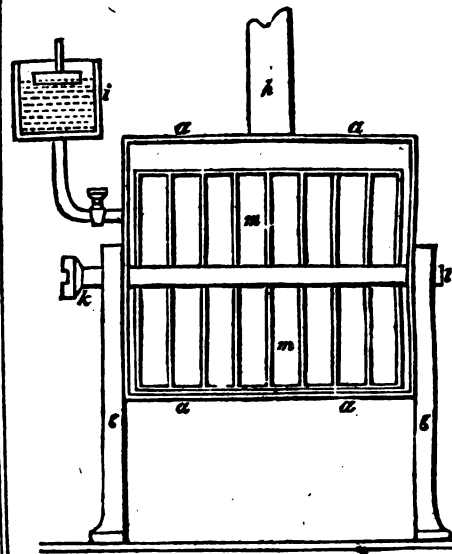

Fig. 3.

worked by an endless screw, *e*, which is moved by a pair of bevel pinions, *f*, and these are acted upon by a small winch and axle attached to the supports, *g, g*. The operation of this machine is as follows: The requisite quantity of flour is sent down from the loft above by the shoot, *h*, and the proper quantity of water is supplied from the small cistern, *i*, which has a float and gauge, with a line and pulley, to indicate the quantity admitted from a larger cistern above, and a pipe and cock to convey the water into the case. The flour and water being admitted, the central axle or shaft, *k, l*, is put into gear with the steam engine by means of the coupling-box, *t*; the axis is thus made to revolve very rapidly, carrying around with it the frame of eighteen knives or mixers, *m, m*. These knives, which are curved, as shown in fig. 2, are two inches wide, and three-eighths of an inch thick at the back; they are connected at their extremities by similar longitudinal knives, which, in revolving, almost touch the lower part of the case. By these means, it is evident that the flour and water must in a short time become thoroughly mixed. The paste is then removed by hand through the door, *c, c*, and placed upon a table, which is as close as convenient to the mixer, and which is now to be described.

This table is shown in an elevation fig. 4, plan fig. 5, and transverse section fig. 6. It has a cast-iron frame and legs, *a, a, a*, a cast-iron bed, *b, b*, (six feet and a half long and three feet wide,) in which are the six holes, *c, c*, &c., to receive friction-rollers, on which run the boards to receive the dough. Fig. 7 is an enlarged section of the side, *a*, of the table; *b*, is the bed; *c*, one of the friction-rollers; and *d*, the board. The sides, *a, a*, of the table support a very heavy cast-iron roller, *e*, eighteen inches in diameter, which, when resting on the table, is about two inches clear of the board, *d*. This roller is made to run alternately, and with great rapidity, from one end of the table to the other, by means of a pair

\* The large gold medal was voted by the Society of Arts for this apparatus.

Fig. 10.

they are about one-third of an inch in diameter, and pointed at their extremities. The effect of all those cutters and pins would, however, be to cause the plate, *d*, to cling to, and lift with it, the sheet of dough. In order to prevent this, a very ingenious contrivance is introduced; a part of which will have been observed in fig. 9. In each hexagon will be seen three arms, branching from the centre. These are formed of iron, and each set is connected with a small vertical iron stem, which passes through the plate, *d*, moving easily, and is surmounted by an iron ball, two inches in diameter, acting as a weight to press the stem and the arms downwards. One of these balls, with its stem and arms, and a portion of the plate, *d*, is shown in fig. 10, where *a*, *a*, *a*, are the three arms; *b*, the stem; *c*, the ball; *f*, *f*, a portion of the dough; and *g*, *g*, a part of the board beneath. It will easily be understood, that when the plate, *d*, rises, the stem, *b*, will drop through its hole, pressed by the ball, *c*,

of beams ten or eleven feet long, attached to centres below the floor under the middle of the table, and made to alternate by a crank from the steam engine; the upper end of one of these beams is seen at *f*, fig. 4, showing the groove in its extremity, to allow the axis of the roller to play in it as the beam alternates. It will now be evident, that when a mass of dough or paste is taken from the mixer and placed upon the table, it must quickly be compressed by the roller into a cake equal in thickness to the distance of the roller from the board, which, in this case, is two inches. During this process a considerable quantity of dry flour is sprinkled on the dough and on the board, a large portion of which would be swept off by the roller and lost, but for the troughs, *g*, *g*, at the ends of the board, which catch and retain it. Notwithstanding this sprinkling with dry flour, a small quantity of dough would occasionally adhere to the roller, were it not kept constantly and perfectly clean by means of two thin knives, extending on opposite sides along its whole length, and attached to two pairs of curved arms, one pair of which, *h*, *h*, is seen fixed to the beam *f*. When this operation is finished, the board with the dough is withdrawn, and another board introduced, on which the process is repeated. The first board and dough being withdrawn, are conveyed on a series of friction-rollers, to a second table, precisely similar to that just described, except that the roller approaches to the board within such a distance as is required for the thickness of the biscuit. The dough, which was reduced to a cake two inches thick at the first table, is cut into pieces, and laid in portions on the second table, where it is quickly brought

down to the proper thickness for biscuits. The board containing this comparatively thin sheet of dough is pushed forward, still running on friction-rollers, towards a machine next to be described, while the workmen at the second table repeat their operations on the fresh portions of the dough which they have received from the first.

The machine, towards which the board and sheet of dough now rolls, is shown in fig. 8: it consists of a strong cast-iron frame, *a*, *a*, *a*, with cross-beams, *b*, supporting three or more pairs of rollers, *c*, *c*, on to which the board is pushed. Immediately above is a thick plate of cast-iron, *d*, *d*, three feet square, which is made to ascend and descend alternately by an eccentric, which acts on the rod, *e*, the lever, *f*, and the guide-rod, *g*. The iron plate, *d*, is shown in the figure at its lowest position; it is, of course, at its highest when the dough and board are brought under it. When this is done, it descends and cuts the dough into hexagonal pieces or biscuits, by means of thin knives, one inch wide, affixed to its under surface, and arranged so as to form hexagonal spaces. A small part of the under side of the plate, *d*, is shown on a larger scale in fig. 9, where, in addition to a portion of the hexagonal knives or cutters,\* will be seen a number of small dots or circles, which indicate the pins or pricklers to give the requisite punctures to the biscuits before they are baked. These pins are as long as the depth of the hexagonal cutters; that is to say, one inch;

\* It will be recollected by those of our readers, who have been subscribers from the commencement, that we gave, in the October number of vol. II, a description and engraving of a cracker machine—of the relative merits of which we are not able to speak.—[Ed. M. M.]

and acting on the dough by the arms, *a, a, a*, will disengage it from the hold of the prickers and cutters. When the plate, *d, d*, descends to cut the dough, of course the arms, *a, a, a*, rise up to the plate, and the stem rises upwards in its hole, carrying with it the ball. There are as many of these balls and stems as there are biscuits, that is to say, about sixty in each square of three feet. These balls would therefore be seen on the upper side of the plate, *d*, in fig. 8; but they are omitted for the sake of avoiding confusion.

The hexagonal cutters do not so completely separate the sheet of dough as to prevent its being put whole into the oven, into which it is introduced by being laid on a plate of iron, which fits on to the handle of the peel by a bayonet-joint. The sheet of dough, when baked, is broken into biscuits, which take the form marked out by the cutters.

The arrangement of the several machines would, in some measure, depend on the form of the building and other circumstances. They should be as near together as is convenient, in order that the boards may pass from one to the other on rollers; the mixing machine should be near the supply of water and flour; and the cutting-machine should, of course, be near the oven. A series of rollers should be fixed against the wall, for the purpose of returning the boards to the first table after they have been emptied. At Portsmouth, this series of rollers was kept constantly revolving by the steam-engine, so that when the empty boards were placed upon any part of the line, they travelled up to the mixer without further attention. —[Transactions of the Society of Arts.]

#### Laws of New York.

An act regulating the specific funds of the State.  
Passed May 9, 1835.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

§ 1. The comptroller shall assign to the common school fund all bonds and mortgages belonging to the general fund; and all bonds and mortgages which shall hereafter be received for account of the general fund, he shall annually, at the close of the fiscal year, assign as follows, viz: First, such an amount thereof to the literature fund as shall be equal to the amount of capital that may at the time be due to that fund from the general fund; and second, the residue of the common school fund. The amount which shall be so transferred to the common school fund, shall be charged to that fund in the books of the comptroller's office, and shall be refunded to the general fund by current receipts into the treasury, on account of the capital of the common school fund.

§ 2. The comptroller shall assign to the common school fund all bonds and mortgages belonging to the literature fund, and all bonds and mortgages which shall hereafter be received for account of the literature fund, including such as shall be assigned to that fund pursuant to the preceding section, he shall assign to the common school fund annually at the close of the fiscal year. And upon every such assignment, he shall at the same time transfer to the literature fund an equal amount of bank stock or public stock belonging to the common school fund.

§ 3. The comptroller shall assign to the common school fund all bonds and mortgages belonging to the Erie and Champlain canal fund; and all bonds and mortgages which shall hereafter be received for account of the Erie and Champlain canal fund, he shall assign to the common school fund annually at the close of the fiscal year. Upon every such assignment, he shall at the same time transfer to the

canal stock belonging to the common school fund; And if the stock so transferred shall be Erie and Champlain canal stock, the said commissioners shall cancel the same; but if it shall be Oswego canal stock, it shall be held by them on account of the Erie and Champlain canal fund.

§ 4. The comptroller shall assign to the common school fund all bonds and mortgages belonging to the Oswego canal fund; and all bonds and mortgages which shall hereafter be received for account of the Oswego canal fund, he shall assign to the common school fund annually at the close of the fiscal year. Upon every such assignment, he shall at the same time transfer to the commissioners of the canal fund an equal amount of bank stock belonging to the common school fund; the stock so transferred shall be cancelled by the said commissioners; and if it shall be Erie and Champlain canal stock, they shall pay the amount thereof to the Oswego canal fund out of the moneys belonging to the Erie and Champlain canal fund.

§ 5. The bonds and mortgages directed by this act to be assigned immediately, and the stocks to be transferred at the same time, shall be so assigned and transferred as of the thirtieth day of September, one thousand eight hundred and thirty four; but if there shall be any loss to the school fund by any of the bonds assigned to it by virtue of this act, the amount of such loss shall be repaid to the school fund from the general fund.

NOVEL SPECTACLE.—The Ogdensburg Times states that a Car is now exhibiting on the Saratoga and Schenectady Rail Road, propelled by a horse walking inside of it; so that instead of a horse travelling before the car, as formerly, he now travels inside the carriage, and propels the car at the rate of a mile in four minutes. This is indeed an age of wonders.

The above described Horse Power Car or Machine, was invented by Eliakim Briggs, of Fort Covington, Franklin county, and are manufactured and sold in Ogdensburg, by S. Bush, Esq. The Power can be applied to every purpose for propelling machinery.

IMPORTANT.—We learn, says the Daily Advertiser of this morning, that the Water Commissioners had a meeting yesterday, and appointed Major Douglass Engineer for constructing the works for bringing water into the city. This is an excellent appointment, and one that will be acceptable to all classes. We learn further that the Commissioners are actively engaged in taking every necessary step for the speedy accomplishment of the great work.

THE WATER LOAN.—The City Stock of one million of dollars, being that part of the Water Loan now required, has been taken by Messrs. Harmon Hendricks and George Newbould, at an average rate of about \$112 for \$100 at five per cent stock payable 1860.—[Jour. of Com.]

[From the New-York Mirror.]

#### Tell Him I Love Him Yet.

[The following exquisite song was written by the author of Lillian, and has never been published.]

Tell him I love him yet,  
As in that joyous time!  
Tell him I never forget—  
Though memory now be crime!  
Tell him when fades the light  
Upon the earth and sea,  
I dream of him by night—  
He must not dream of me!  
Tell him to go where Fame  
Looks proudly on the brave,  
And win a glorious name  
By deeds on land and wave.  
Green, green upon his brow  
The laurel wreath shall be—  
Although that laurel now  
Must not be shared with me!  
Tell him to smile again  
In pleasure's dazzling throng  
To wear another's chain,  
To praise another's song!  
Before the loveliest there  
I'd have him bend the knee,  
And breathe to her the prayer  
He used to breathe to me!  
Tell him that day by day  
Life looks to me more dim—  
I falter when I pray,  
Although I pray for him.  
And bid him when I die  
Come to our favorite tree—  
I shall not hear him sigh—  
Then let him sigh for me!

#### AGRICULTURE, &c.

[From the Horticultural Register.]

ON HEDGES.—Hedges, or live fences, are becoming every day more necessary. In many parts of the country timber is too scarce for valuable fencing materials, and even in the few agricultural districts where stone abounds, the progress of cultivation, and the increasing wants of our growing towns, and villages, will sooner or later cause the farmer to resort to living materials for fencing his lands. For the Garden, hedges are undoubtedly preferable to all other means of inclosure in this country, where walls are so little used or needed. Their imperviousness, their durability, and their beauty, surpass either the most nicely constructed paling, or the firmest and smoothest wall. And what harmonizes so well with the pleasing green of the field, or the garden, as the verdant foliage of the live fence?

What, then, is the best material for hedges? We, who are accustomed to draw a large share of our horticultural information from a nation older in this as in other arts and sciences, are taught to believe that the proper answer to this question is, the *English White Thorn*. But experience is teaching us that this is an error. How many millions of the English thorn have been planted in this country, and how few of them ever make a healthy and permanent hedge! The secret lies in the climate. The summers of England are moist and cool, when compared with ours. The powerful sun and dry climate, which bring to plentiful maturity the Indian corn, the peach and the melon, are not the sun and the climate which are congenial to the European Hawthorn. They are too fine and dry. In the moist and showery months of April, May and June, the Hawthorn looks exceedingly promising; its shoots appear green and healthy; but soon the hot July sun bursts forth, and it is checked almost as by a nipping frost. Then the insects attack it, and by the last of August the hedge is stunted and already leafless! Hence its growth is exceedingly slow, and as it is a prey to insects, which cause its decay, and to defoliation by the intensity of the summer sun, it is neither durable or beautiful. It is true, that during the first two or three years of its growth, its healthy and vigorous appearance is very flattering; but this is only whilst the plants are young, and before their interlacing roots and branches have found it necessary to attract nourishment from a limited portion of the surrounding soil.

It goes far to corroborate the opinion, that the dryness of our soil and atmosphere are the first causes of failure with the English Hawthorn, to find that in situations naturally moist and damp through the summer, it appears to grow with equal luxuriance, and to attain the same degree of maturity, as in Europe; but, as only small portions of the farm, and no good garden, will be found in moist localities, it is therefore necessary to search for some other material more generally adapted to the wants of our wide-spread territory.

There are over twenty species of *Crataegus*, or Hawthorn, indigenous or growing wild in North America alone—more than the aggregate number in the known world besides! Shrubs and trees which, for sharpness and abundance of thorns, beauty of foliage, rapidity of growth, and compactness of form, (when properly trimmed,) yield to none others of the genus. Is it not remarkable, that with this abundance

and choice of materials for hedges, scattered by bountiful nature through every wood, and by every high-way side, that we should have to stretch forth our hands, and borrow from another clime a starved and lingering exotic? But so it is; and Horticulturists, as well as other men, must gather knowledge from experience. After repeated trials and failures with the imported plants, we are now content to turn our attention to the natives. Here we find species which are perfectly hardy, and to which our sun and climate are as necessary as they are injurious to the foreign. Four species have been already tested, and found to be admirably adapted for hedges, viz.: the Cockspur or Newcastle thorn (*Crataegus crus galli*), the Washington thorn (*C. populi folia*), and two others, only known by the common name of thorn bush (*C. coccinea* and *C. punctata*.) Of the Washington and Newcastle thorns, very fine hedges are now thriving in many sections of the country. They are found to grow with more luxuriance, to retain their fine vivid foliage through the hottest of the summer, and, in common with many other American trees, to assume an autumnal tint of the most beautiful crimson and orange, which remains until severe frosts. These two species seem to adapt themselves to almost any soil; but if not, their places may be supplied by such species as are found naturally to thrive best in the neighborhood—for almost every section of the country abounds with some species of Hawthorn. Perhaps in the Southern States, they will ascertain that some of the peculiarly southern species succeed best.

For situations where strong hardy hedges are wanted, in a short period of time, the three-thorned Acacia (*Gleditsia triacanthos*) will be found an excellent plant. Hence it is well adapted to farms; but from its rampant growth, it is difficult to keep it sufficiently close in its side spray properly to shelter the garden from all its enemies. Among the Hedge plants which demand the attention of the Horticulturist, are the Buckthorn (*Rhamnus catharticus*), which makes an excellent fence; the Privet, long in use, and a beautiful and verdant inner shelter to the garden, but not a sufficient protection against cattle; and the *Mespilus pyracantha*, or Evergreen thorn, ornamented in its white blossoms and coral berries. European publications speak in high terms of the great beauty and excellence of the Japan Quince (*Cydonia japonica*)—already known here as a charming flower shrub,—used there as a garden hedge plant. We have great hopes of success, also, with the Osage Orange (*Maclura aurantiaca*), a native of the West; and its glossy green foliage, stone thorns, and rapid growth, will place it in the first rank of hedge plants. A. J. DOWNING.

Newburgh, N. J., March.

[From the Maine Farmer.]

**MADDER.**—Since the commencement of this volume, we have occasionally presented you with communications on the subject of raising Madder. Madder is a root which is much used by the dyer and calico printer, and has hitherto been and is even now brought from Europe in vast quantities. Indeed, nearly all that is used in America is brought from across the Atlantic, for very few have ever cultivated it in the United States, or till lately have even thought of the thing. Mr. Russel Bronson, of Bridgewater, Oneida county, N. Y., has successfully cultivated

it for a few years past, and has done much in calling the attention of the public to its culture.

We published some time ago his remarks in answer to some queries of ours in regard to the prospect of its doing well in Maine. Since then we have learned that a root or two was formerly grown in the garden of E. Wood, Esq., in this town, where it lived for several years without any particular care being taken of it. It was kept as a sort of curiosity, and was finally probably ploughed up and thrown away. There is, therefore, no doubt but that it will do well here, as far as soil and climate is concerned.

Mr. Bronson, who seems to have had as much experience in the culture of this root, and who has given what late information upon the subject we have had, is very sanguine that it will ultimately be one of the most valuable crops that the farmer can raise. He is anxious to get up a company for carrying on the cultivation on a large scale, and we verily believe the projected speculation has much more of reason in it than most of the schemes which are so eagerly embraced at the present day. The following extracts from a private letter will give an expose of his plan. Mr. Bronson, we hope, will excuse us for publishing his remarks. As for the ridicule which he mentions, that is a thing of course. There is always a set of wise-acres in every neighborhood, who are always ready to hoot and sneer at whatever they either envy or do not understand.

"I will not trouble you at this time by explaining the difference that should be made between the price of madder roots sold in the fall of three years old, and those sold in the spring, as it is my intention to send a communication to the editors of all the agricultural papers who have my name on their books as a subscriber, detailing the most approved mode of culture, the kind of soil, the location, digging, washing (or rinsing, as the soil may be heavy or light,) drying, grinding, &c. I would wish to remark here that I have not as yet given to the public any account of the method of digging, washing, drying and grinding, as I was aware that there would be no necessity of giving this information to the public until I should be compelled to search for the best plan in digging, washing, drying and grinding the madder from 8 acres next fall. The results of my experiments will be given to the public through the columns of the "Cultivator," "Genesee Farmer," "N. E. Farmer," and "Maine Farmer," in November next. There is not, I believe, but one cultivator, at a distance from this, whose crop is at this time of a suitable, but especially profitable, age to take up. I saw yesterday 1000 acres of land, owned by several farmers, that would, without a shadow of doubt on my mind, produce once in 4 years for 20 years a clear profit, decently managed, of two hundred thousand dollars—this would include the whole expense of rent of land, seed, cultivating, digging, drying, &c., and the interest of land and building included. You

perhaps will say this looks well on paper, as one correspondent says to me—alluding to my communications as well as others—"My neighbors are the poorest farmers in the Union," they say; "That Cultivator is a queer paper, I don't believe them large stories;" "They ridicule my project in attempting the culture of madder." In my former communications to the public, I have never stated the crop at 3 years to be over 2000 lbs. ground madder—we now raise in hills 2400 hills to an acre—4000 in 4 years. We have never yet dug at 4 years until last fall, which produced 4000 lbs. ground madder from an acre at an average—what it will do from an acre planted in drills 3 feet wide, 4 vacant, and when finished 5 or 6 wide, 1 to 1½ feet vacant, we do not know, but supposing it should produce but 5000 lbs. at 12½ cents, (top and bottom roots ground,)—average price of Dutch madder in New-York market for 13 years past 15 cents, which is lower than the ten preceding years—this would amount to, at 12½ cents, \$625—taking out the outlay \$140 to 160; it leaves great profits. I have offered some of my neighbors, some time since, that if they would let me select some of their best land, and they go through with the process according to my directions, I would warrant them \$100 clear of all expense per acre, they giving me the balance. Some would object to planting, as it took 3 or 4 years before any returns could be expected. I would ask how old a horse must be before he is fit for business. Others again objected that by the time their second crop should be ready for digging, the market would be glutted. I here remarked, that several estimates had been made relative to the quantity required for the consumption of the United States, varying from forty-five to seventy-five thousand acres. There is at this time in the ground, to be planted this spring, and engaged for 1836, not much over 100 acres. I have had it in contemplation for some time past, in offering my services to some capitalists, say \$30,000 in 8 or 10 semi-annual instalments—would take a sixteenth part of the stock and superintend the establishment for \$1000 per annum, to be located on the prairies of Ohio, Michigan, or perhaps Illinois. I should be pleased to receive communications on the subject. I should think it very important to the prosperity of a company, that dealers in the article residing in Boston, New-York, Albany, Utica, Rochester, Buffalo, and Detroit, should be associated with the company as stockholders and agents. I am about presenting the subject to a few gentlemen in Utica—a greater sum could be employed if wished. Respectfully yours,

R. BRONSON.

The whole amount of wool raised last year in the United States was seventy-five millions of pounds, in addition to which about three millions were imported from abroad, making the whole quantity manufactured in American factories seventy-eight millions of pounds. In addition to the above, manufactured woollen cloth was imported to the amount of six millions, making the entire consumption in this country eighty-four millions of pounds.—[Balt. American.]

## NEW-YORK AMERICAN.

MAY 30—JUNE 5, 1833.

## LITERARY NOTICES.

A NEW FRENCH AND ENGLISH PRONOUNCING DICTIONARY BY F. C. MEADOWS, M. A. of the University of Paris—first American edition: corrected and improved by GEO. FOLSOM, M. A.—1 vol.: N. Y., PETER HILL & Co.—We look upon this as a very valuable contribution to the cause of accurate knowledge. The pronunciation of the French is simplified to the American learner, as much, as through the eye, it ever can be, by employing the familiar sounds of his own language, to convey to him that which he is to give to the French word. So far as we have examined it, this is successfully accomplished, though at first sight frequently, we were half disposed to doubt about it. Yet on pronouncing the word to ourselves, and then comparing it with the sounds set down in the book, strange and uncouth looking as some of these are—we found them accurate. There is too, by way of introduction, quite a good abridged grammar of the French tongue: the whole is very well printed though in a small type.

PRaise AND BLAME, by CHARLES WILLIAMS. New York, BLISS, WADSWORTH & Co.—This is a little volume of "true stories," with a sort of homily at the end of each, dispensing praise and blame according to the merits of the case, and intended for the improvement of young children.

SCRIPTURE CATHECISM, &c. &c.: New-York GRIFFIN & Co.—The Catechism of the Westminster Divines, with the Rev. Dr. Henry's questions and answers, and a Catechism for children by the Rev. John Brown, are included in this little book.

FACTS, FEELINGS AND FANCIES, by CHARLES JAMES CONNOR, 1 vol.: New-York BLISS, WADSWORTH & Co. For papers written under the circumstances of these, "in the intervals of labor or disease by one who has never known the advantages of education,"—they are not without merit.

THE CONQUEST OF FLORIDA, BY HERNANDO DE SOTO: by THEODORE IRVING, 2 vols., Philadelphia, CAREY, LEA & BLANCHARD—for sale by WILEY & LONG.—The great poet has asked hypothetically, "what is there in a name?": a great deal sometimes, and sometimes little enough. In the names associated in this new work, by an American on an American theme, there is much we think to attract—and the promise of the title is made good by the performance. The dedication of these pages, by the author, to his uncle Washington Irving, is affectionate and becoming. It was while with that uncle in Spain, that the perusal in Spanish of the history of *Hernando de Soto's* marvellous expedition to Florida—written by the Inca *Garcilaso de la Vega* first fired the young imagination of our author, to the scenes and events there recorded; and falling in afterwards with an anonymous narrative of the same occurrences, purporting to be written by a Portuguese soldier,—he was led on to plan, and after due investigation and research, to write a "full account of an expedition, which throws such an air of romance over the early history of a portion of our country."

It will be gathered from this statement, that, although *Garcilaso de la Vega* is the main authority relied on, it is not a translation, but a compilation, in which abundant room is left for the exercise of judgement in the relation of, and taste in the arrangement, and manner of setting forth, the materials employed.

Our readers will, we think, find that these qualities are both evinced in the volumes now presented to them.

THE YOUTH'S BOOK, OF TALES AND SKETCHES ILLUSTRATIVE OF MORAL DEPARTMENT; by JOHN BOWRING, LL. D. first American edition, Philadelphia, H. CONRAD and E. PARSONS.—This is an American re-publication, under an altered title, of a work of Dr. Bowring's, entitled "Minor Morals for Young People," and intended by him to illustrate the "greatest happiness principle:" that is to say, that, "it is impossible to add to the stock of virtue, without adding to that of felicity, or to increase the amount of felicity without increasing that of virtue." It is a charming little book, which boys and girls of ingenious minds cannot read without being improved by its well told stories. We do not think the very indifferent wood cuts, with which it is "embellished," any additional attraction.

NARRATIVE OF A SECOND VOYAGE in search of a North West passage, and of a residence in the Arctic Regions, during the years 1829, '30, '31, '32 and '33, by Sir JOHN ROSS, Captain in the Royal Navy, &c. &c. 1 vol. 8vo. Philadelphia, E. L. CAREY & A. HART.—The marvel of Capt. Ross' return, with the survivors of his crew, after long years of absence, and when hope even, had fled from the breast of all but a few daring philanthropists, like Capt. BACK,—occupied for a space all attention; and the record of the extraordinary exposure and escape of these Arctic navigators, was looked for with intense interest. We know not why this interest was balked, by the long delay that has intervened, since the restoration of Capt. Ross, and the publication of the narrative, but apprehend that it may not be as eagerly sought, as earlier it would have been. As it is, the book had not, at the latest dates, been published in England, so that we have here our copy, printed from the sheets, sent from England, as early as possible.

In a preliminary dissertation, Capt. Ross states this, to our judgment, sound conclusion.

"It remains therefore, to say, that while my voyage and its results, have demolished all hypothesis and hopes, [of finding "a North West passage,"] but those which may still be entertained respecting Lancaster Strait, and the Pole—if, indeed, the latter has still an advocate remaining—there are now fewer temptations than ever to make any fresh attempt for solving this problem."

There are many passages in this narrative—written plain unpretending style—which we would gladly find room for, but must content ourselves with that, describing the falling in of these forlorn navigators, with the ship which rescued them. It is simple and impressive.

26th March, 1833.—At four in the morning, when all were asleep, the look out man, David Wood, thought he discovered a sail in the offing, and immediately informed Commander Ross, who, by means of his glass, soon saw that it was in reality a ship. All hands were immediately out of their tents and on the beach, discussing her rig, quality, and course; though there were still some despairers who maintained that it was only an iceberg.

No time was however lost, the boats were launched, and signals made by burning wet powder; when, completing our embarkation, we left our little harbor at six o'clock. Our progress was tedious, owing to alternate calms, and light airs blowing in every direction; yet we made way towards the vessel, and had it remained calm where she was, should soon have been alongside. Unluckily, a breeze just then sprang up, and she made all sail to the southeastward; by which means the boat that was foremost was soon left astern, while the other two were steering more to the eastward, with the hope of cutting her off.

About ten o'clock we saw another sail to the northward, which appeared to be lying to for her boats; thinking, at one time, when she hove to, that she had seen us. That, however, proved not to be the case, as she soon bore up under all sail. In no long time it was apparent that she was fast leaving us; and it was the most anxious moment that we had yet experienced, to find that we were

near to no less than two ships, either of which would have put an end to all our fears and all our toils, and that we should probably reach neither.

It was necessary, however, to keep up the courage of the men, by assuring them, from time to time, that we were coming up with her; when, most fortunately, it fell calm, and we really gained so fast, that, at eleven o'clock we saw her heave to with all sails aback, and lowered down a boat, which rowed immediately towards our own.

She was soon alongside, when the mate in command addressed us, by presuming that we had met with some misfortune and lost our ship. This being answered in the affirmative, I requested to know the name of his vessel, and expressed our wish to be taken on board. I was answered that it was "the *Isabella* of Hull, once commanded by Captain Ross;" on which I stated that I was the identical man in question; and my people the crew of the *Victory*. That the mate who commanded this boat, was as much astonished at this information as he appeared to be, I do not doubt; while, with the usual blunderheadedness of men on such occasions, he assured me that I had been dead two years. I easily convinced him, however, that what ought to have been true, according to his estimate, was a somewhat premature conclusion; as the bear-like form of the whole set of us might have shown him, had he taken time to consider, that we were certainly not whaling gentlemen, and that we carried tolerable evidence of our being "true men, and no impostors," on our backs, and in our starved and unshaven countenances. A hearty congratulation followed of course, in the true seaman style, and, after a few natural inquiries, he added that the *Isabella* was commanded by Captain Humphreys; when he immediately went off in his boat to communicate his information on board; repeating that we had long been given up as lost, not by them alone, but by all England.

As we approached slowly after him to the ship, he jumped up the side, and in a moment the rigging was manned; while we were saluted with 3 cheers as we came within cable's length, and were not long in getting on board of my old vessel, where we were all received by Captain Humphreys with a hearty seaman's welcome.

Though we had not been supported by our names and characters, we should not the less have claimed, from charity, the attentions we received, for never was seen a more miserable-looking set of wretches; while, that we were but a repulsive-looking people, none of us could doubt. If, to be poor, wretchedly poor, as far as all our present property was concerned, was to have a claim on charity, no one could well deserve it more; but, if, to look so, be to frighten away the so called charitable, no beggar that wanders in Ireland could have outdone us in exciting the repugnance of those who have not known what poverty can be. Unshaven since I know not when, dirty, dressed in the rags of wild beasts instead of the tatters of civilization, and starved to the very bones, our gaunt and grim looks, when contrasted with those of the well-dressed and well-fed men around us, made us all feel, I believe for the first time, what we really were, as well as what we seemed to others. Poverty is without half its mark, unless it be contrasted with wealth: and what we might have known to be true in the past days, we had forgotten to think of, till we were thus reminded of what we truly were, as well as seemed to be.

But the ludicrous soon took place of all other feelings; in such a crowd and such confusion, all serious thought was impossible, while the new buoyancy of our spirits made us abundantly willing to be amused by the scene which now opened. Every man was hungry and was to be fed, all were ragged and were to be clothed, there was not one to whom washing was not indispensable, nor one whom his beard did not deprive of all English semblance. All, every thing, too, was to be done at once; it was washing, dressing, shaving, eating, all intermingled, it was all the materials of each jumbled together; while in the midst of all, there were interminable questions to be asked and answered on all sides; the adventures of the *Victory*, our own escapes, the politics of England, and the news which was now four years old. But all subsided into peace at last. The sick were accommodated, the seamen disposed of, and all was done, for all of us, which care and kindness could perform. Night at length brought quiet and serious thoughts; and I trust there was not one among us who did not then express, where it was due, his gratitude for that interposition which had raised us all from

a despair which none could now forget, and had brought us from the very borders of a not distant grave, to life and friends and civilization.

Long, accustomed, however, to a cold bed on the hard snow or the bare rock, few could sleep amid the comfort of our new accommodations. I was myself compelled to leave the bed which had been kindly assigned me, and take my abode in a chair for the night, nor did it fare much better with the rest. It was for time to reconcile us to this sudden and violent change, to break through what had become habit, and to inure us once more to the usages of our former days.

HELON'S PILGRIMAGE TO JERUSALEM, translated from the German of FREDERICK STRAUSS, revised and enlarged by BARON STOW, Pastor of the 2d Baptist Church, Boston. 1 vol. Boston. Wm. D. TICKNOR. A picture of Judaism, in the century which preceded the advent of our Saviour, is attempted in this work, which was first published about ten years ago, and received with marked interest. The design is one that cannot fail to attract all readers, who, in the delineations of such a work, if executed with fidelity, would find constant elucidations of the book of books—the Bible. That it is so executed, is, we think, to be confidently inferred, from the desire frequently expressed, in this country, as we are told in the prefatory notice of the American editor, to procure the work, as aiding and facilitating theological studies. Hence, the present publication, which, by the omission of the very copious and learned notes, that accompanied the English edition, and the condensing two volumes into one, is furnished in a cheap and accessible form.

The story is one that puts before the reader the whole domestic life and manners of the Jews.

CELEBRATION OF THE FORTY-SEVENTH ANNIVERSARY OF THE FIRST SETTLEMENT OF THE STATE OF OHIO BY NATIVE CITIZENS. CINCINNATI. LODGE, L'HOMMEDIU & Co.—Under this title we have just received from Cincinnati, a pamphlet embodying the proceeding of a public celebration on the 7th April last—which, we shall ever consider it a peculiar piece of good fortune, that it was our accidental happiness to witness, and share in.

Our columns to day were too much pre-occupied to permit us to extract, or condense from this pamphlet, any connected account of what it so well commemorates; and we, therefore, only print a single letter from among the many very clever ones that were written by those who, invited from a distance, were unable to attend. It is that of the author of *Swallow Barn*, and, although from the absence of all the associations and feelings of the day and place where it was received and read aloud, it can not strike our readers with any thing like the delight, that it did the three or four hundred whole-souled *Buckeyes*, who had grown up with the strapping "blooming girl," whom it so admirably describes, it will yet, with its accompanying toasts, be deemed, we think, a capital effort for such an occasion.

BALTIMORE, March 27th, 1835.

Gentlemen—I have received the letter of the committee of invitation, for your approaching State festival on the 7th of next month. I very earnestly regret that I cannot be with you. My professional engagements leave me no time for such a journey before midsummer.

It has long been my purpose, to which I have looked forward as a source of much future pleasure, to make a visit to the West, and especially to your beautiful city. I have deferred the enterprise from summer to summer, I can scarcely tell why, unless it be from some lingering remains of a feeling which was common to my boyhood, that it was well to wait until the West grew ripe, and roads grew better, and towns more populous. For we had a current prophecy then, that the West, from being the child, would become the mother of nations; and in this boyish fancy I have waited that I might see her as a matron. Suddenly, before I was aware,

the prophecy has become truth—the West that I dreamed of is no longer there—the wilderness is gone—the Indian is gone—and even the old boatmen have vanished. You have sent colonies still farther towards the setting sun—and the west is a thousand miles away. Ohio was then the chubby and blooming girl of the family, who grew too fast for her garments, in spite of all the tucks and drawing strings and broad plaits, made "to let go." But she is now in vigorous womanhood, not following in the train of civilization and refinement—but leading it, and staying the balance of the Union, by the weight of her moral and intellectual strength.

You have a noble country, gentlemen, and it is no small source of its happiness, that it occupies a station which draws upon it the kindest regards from all the other members of the Confederacy.—Your relations of friendship and interest are intimate with the North, and the Centre. There is not a state in the circle, that has not reason to rejoice in the prosperity of Ohio.

As a Baltimorean, I feel myself subsisting under affinities with you, and am accustomed to bring into my familiar reckoning, the certainty of the most various and agreeable social relations with your People. My feelings in this matter are the general feelings of my townsmen. We have just resolved to level the Alleganics, widen the Ohio, and abolish the mile stones, in the romantic, but no longer impracticable exploit of annihilating time and space. When this is achieved, gentlemen we shall be happy to see you and your friends, on any day when you may take a fancy to rise early, with us, at dinner in Baltimore.

I heartily wish we could get this regulated by the 7th of April, but I fear the time is too short.—I will beg you therefore, that you will allow me so far to participate in the festival, as to offer the following sentiments:

"The States of Ohio and Maryland.—I through fire and water they will hold together: mountains shall not sunder them."

I beg leave to subscribe myself, very truly yours,  
JOHN P. KENNEDY.

[From the United States Medical and Surgical Journal for April.]

IMPROVED EDITION OF GOOD'S STUDY OF MEDICINE. By Dr. A. Sidney Doane.

We mentioned in our last, that the Messrs. Harpers, of New York, having lately received a copy of the last London edition of this important work, have committed it to the press for immediate republication. The present edition appeared in London in December last; it is a greatly enlarged copy, with additions from the last manuscript improvements of the learned author, and still farther increased in value by many additions of a practical character by the distinguished editor, Prof. Samuel Cooper, the writer of the popular surgical dictionary, and other works. The contemplated edition now about to appear from the accurate and excellent press of the Harpers will include the whole work and emendations of Dr. Good, and all additions and improvements by Cooper; and to these throughout will be still further added a large and copious body of practical notes by the American editor, Dr. Doane, of New York, who has for some time been advantageously known to professional readers and practitioners as a gentleman of eminent erudition and capacity. The notes and improvements of Dr. Doane will embrace the leading facts and principles of American practice; and these researches of the editor will enable him to associate with the labors of Dr. Good a large amount of the opinions and observations which have resulted from the clinical experience of the most prominent American authors throughout the United States.—It is believed that the fidelity with which this act of justice will be performed towards the character and capacities of native writers in different parts of our widely-extended country, will give to the projected undertaking a consideration far superior to that of any former edition of this elaborate and valuable work.

We feel justified in thus noticing the present edition of the Study of Medicine, inasmuch as we have carefully examined a considerable number of the sheets already printed; and if Dr. Doane continues to exercise the same industry and judgment throughout the book, we feel satisfied that the profession will be subjected to lasting obligations to him for his services.

We are informed that some few weeks must necessarily elapse before the appearance of the present work, as it is extensive and will be ex-

ecuted in a very beautiful manner; it will be included in two large octavo volumes, and offered for sale at a very reasonable price.

Extract from "The Evening Voluntaries."

By WORDSWORTH.

Calm is the fragrant air, and loth to lose  
Day's grateful warmth, tho' moist with falling dews.  
Look for the stars, you'll say that there are none:  
Look up a second time, and one by one,  
You mark them twinkling out with silvery light,  
And wonder how they could elude the sight.  
The birds, of late so noisy in their bowers,  
Warbled awhile with faint and faltering powers,  
But now are silent in the dim-seen flowers:  
Nor does the village church-clock's iron tone  
The time's and season's influence disown;  
Nine beats distinctly to each other bound  
In drowsy sequence; how unlike the sound  
That, in rough winter, oft inflicts a fear  
On fireside listeners, doubting what they hear!  
The shepherd, bent on rising with the sun,  
Had closed his door before the day was done,  
And now with thankful heart to bed doth creep,  
And join his little children in their sleep.  
The bat, lured forth where trees the lane o'er shade,  
Flits and refits along the close arcade:  
Far heard the dor-hawk chase the white moth  
With hissing note, which Industry and Sloth  
Might both be pleased with, for it suits them both.  
Wheels and the tread of hoofs are heard no more;  
One boat there was, but it will touch the shore  
With the next clipping of its slackened oar;  
Faint sound, that, for the gayest of the gay,  
Might give to serious thoughts a moment's away,  
As a last token of man's toilsome day!

If all too much of Earth there be.

By O. W. W.

If all too much of Earth there be  
In feelings I have breathed to thee,  
If dreams that in my soul have dwelt,  
Seem wilder than thine own hath felt—  
O think how I have sought to be  
In every hope and dream like thee,  
And, when I heard thy sunny tone,  
Have wished my spirit like thine own!  
If sometimes I have dared to speak  
A word that crimsoned o'er thy cheek,  
If "dearest" be too fond a name  
For me to breathe, or thee to claim—  
Yet think how I have checked each word,  
By which my lip, not heart, hath erred,  
And, in its pure and sinless tone,  
Have wished my spirit like thine own!  
If Love my wayward bosom move,  
To aught thy heart may disapprove,  
If Passion and an earthly dream  
Within my soul a moment gleam—  
O think how much thou canst impart—  
Of Virtue to my restless heart,  
And breathe a sweet and sunny tone,  
To make my spirit like thine own!

[FOR THE NEW-YORK AMERICAN.]  
The Blasted Oak.

From a Painting by G. A. LUDLOW.

Dark on the heath—the night gloom fell,  
Loud sighed the wind, with fitful spell  
The lightning glared around,  
And meeting clouds with angry roar,  
The burthen of the tempest bore  
Far o'er the trembling ground.  
Hark! heard ye not 'mid torrents borne,  
The echo of a distant horn  
Upon the moaning blast?  
And clattering hoofs? as if with speed,  
For life—for life—spurred—on a speed  
It comes, and now—'tis past.  
With bloody speed—and frantic men,  
Too well the rider's haste I ween  
Of crime, of terror spoke,  
And ever and anon he threw  
A fearful glance—where lonely grew  
On old and gnarled oak.  
For 'neath that leafless trunk hath lain,  
The mould'ring corpse of one long slain,  
Oh! God! can such things be?—  
The rider spurred'd his courser on—  
Oh! for the blessed beam of morn,  
To light me cheerily.  
On—on—the maddened courser fled,  
His snorting nostrils speak his dread—  
With visage ghastly pale,  
The horseman spurred'd—my gallant steed  
Why falter, at thy master's need?  
Why tremble thus, and quail?  
Avaunt ye spirits of the slain;  
My horn shall gaily sound again,  
To bid yon Loiterers haste—  
He said—and wound a trembling blast—  
Started his horse, as mourning, past  
A shadow o'er the waste.  
'Tis he—the murderer faintly cries,  
Oh! God! I see his pleading eyes,  
That wide and bleeding gash—  
Ha! ha! 'tis but a shadow born,  
Of clouds—(such oft the earth hath worn)  
Scared by the lightning's flash.  
They neared the spot—a forked light,  
Played 'round the tree, and by the bright,  
And vivid flame it cast—  
I saw the murderer writhing fall  
Then closed above, nights glooming pall  
And louder moaned the blast.

ELLA.

## SUMMARY.

Messrs. Catey, Lea & Blanchard will publish, on Saturday next, *The Cragon Miscellany*, number 2, containing *Abbottford and Newstead Abbey*, subjects of lively interest for general readers. The volume is of 230 pages, and printed as the first.

*Celebration of the North Carolina Declaration of Independence.*—The Mecklenburg Declaration of Independence was celebrated with great eclat at Charlotte, N.C. on the 20th ult. A vast concourse of citizens from North and South Carolina assembled upon the occasion, including his Excellency the Governor, and several high official functionaries of the latter State. The Declaration was read by Mr. Osborne, and an oration delivered by Franklin Smith, Esq. The military was in attendance in great numbers, and the whole ceremonies were of the most imposing character. Upwards of six hundred persons sat down to a sumptuous dinner, and at evening there was a splendid ball. "Charlotte," says the Journal of that place, "has not seen such a day for sixty years."

*NEW ENGLAND ANNIVERSARIES.*—The anniversary of the battle of Lexington was celebrated on the spot recently, and from the oration of *Edward Everett* on the occasion—a man who, as Johnson said of Goldsmith, "touches nothing that he does not adorn"—we copy a fine account of the battle and its circumstances.

*Newburyport*, too, has been celebrating her two hundredth anniversary—and with genuine New England feeling.

**Mr. Everett's Address at Lexington.**

We are glad to set before our readers a portion of this Address, in which the circumstances of the Battle of Lexington are related. The discourse itself yields to none of the former efforts of its author, in eloquence, fullness or research, or adaptation to the occasion.—[Boston Daily Adv.]

On Saturday, the 15th of April, the provincial Congress, then in session at Concord, adjourned to meet again on the 10th of May. It is probable that the intelligence of this event had not reached General Gage in Boston, when, on the same day, he commenced his arrangements for the projected expedition. The grenadiers and light infantry were relieved from their several stations in Boston, and concentrated on the common, under pretence of learning a new military exercise. At midnight following, the boats of the transport ships, which had been previously repaired, were launched and moored under the sterns of the men-of-war in the harbor. Dr. Warren, on his way home from the Congress on Saturday, had expressed to the family of Mr. Clark, his firm persuasion, that the moment was at hand when blood would flow. He justly regarded the military movements of the following night, as a confirmation of this opinion, and despatched Colonel Paul Revere the next day, to this place, to bring the intelligence to Messrs. Hancock and Adams. They naturally inferred from the magnitude of the preparations, that their own seizure could not be the sole object, and advised the committee of safety, then sitting at West Cambridge, to order the distribution into the neighboring towns of the stores collected at Concord. Colonel Paul Revere, on his return to town on Sunday, concerted with his friends in Charlestown that two lights should be shown from the steeple of the North Church, if the British troops should cross in boats to Cambridge, and one, if they should march out over Boston neck.

Wednesday the 19th was fixed upon as the eventful day. Ten or twelve British officers were sent out the day before on horseback, who dined at Cambridge, and at nightfall scattered themselves on the roads to Concord to prevent the communication of intelligence from the town. Early information of this fact was brought to this place by Solomon Brown\* of Lexington, who returned late from Boston market on the afternoon of the 18th.

\* Mr. Brown is still living, but from the distance of his place of residence, was not able to attend, with the other survivors of Captain Parker's company, (ten in number,) at the celebration of the anniversary.

and passed them and was passed by them several times, as they sometimes rode forward or fell back on the road. A despatch to the same effect was also sent by Mr. Gerry of the committee of safety, at West Cambridge to Mr. Hancock, whose answer, still preserved, evinces the calmness and self-possession, which he maintained at this approaching crisis. In consequence of this information, a guard of eight men, under the late Colonel Monroe, then a sergeant in the Lexington company, was marched in the course of the evening to Mr. Clark's house, for the protection of Messrs. Adams and Hancock. At the same time Messrs. Sanderson, Loring, and Brown, were sent up towards Concord, to watch the movement of the officers. They came upon them unawares in Lincoln, and fell into their hands. About midnight, Col. Paul Revere, who had left Boston by direction of Doctor Warren, as soon as the movements of the troops was discovered, and had passed by the way of Charlestown, where he narrowly escaped two British officers, through Medford, and West Cambridge, giving the alarm at every house on the way—arrived at Mr. Clark's with despatches from Dr. Warren, for Hancock and Adams. Passing on towards Concord, Revere also fell into the hands of the British officers in Lincoln, but not till he had had an opportunity of communicating his errand to young Dr. Prescott, of Concord, whom he overtook on the road. At the moment Revere was arrested by the officers, Prescott succeeded in forcing his way through them, and thus carried the alarm to Concord. The intelligence sent by Dr. Warren to Messrs. Hancock and Adams, purported that a large body of the King's troops, (supposed to be a brigade of 1200 or 1500 men,) had embarked in boats from Boston."

After the detention of an hour or two in Lincoln, the British officers were informed by Col. Revere, of all the measures he had taken to alarm the country; and deemed it expedient for their own safety to hasten back toward Boston. On their way toward Lexington, they put many questions to their prisoners, as to the place where Messrs. Adams and Hancock were residing. As they approached Lexington, the alarm bell was ringing, and a volley was fired by some of the militia, then assembling on the green. Upon this they hastened their flight, and just as they entered the village their prisoners escaped from them. Colonel Revere repaired to the house of Mr. Clark, and the general apprehensions relative to his distinguished guests, having been confirmed by the interrogatories of the British officers, Messrs. Hancock and Adams were persuaded with great difficulty to withdraw from the immediate vicinity of the road. On the return of Colonel Revere to the centre of the village, he met Captain Thaddeus Bowman coming up the road, in full gallop, with the news that the British troops were at hand.

It was at this time, between four and five o'clock in the morning. Three messengers had been sent down the road, to ascertain the approach of the British army. The two first brought no tidings, and the troops were not discovered by the third, Bowman, till they were far advanced into the town. They had been put in motion about seven hours before on Boston Common. They crossed in boats, near the spot where the Court House now stands in East Cambridge; and there took up their march, from eight hundred to one thousand strong, grenadiers, light infantry, and marines. They crossed the marshes, inclining to their right, and came into Charlestown and West Cambridge road, near the foot of Prospect hill. It was a fine moonlight chilly night. No hostile movement was made by them, till they reached West Cambridge. The committee of safety had been in session in that place at Wetherbee's tavern; and three of its distinguished members, Vice President Gerry, Col. Lee, and Col. Orne, had taken up their lodging for the night, at the same house. The village, having been alarmed by Colonel Revere, was on the alert at the approach of the army; and Messrs. Gerry, Lee, and Orne, had risen from their beds and gone to their windows, to contemplate the strange spectacle. As the troops came up, on a line with the house, a sergeant's guard was detached to search it; and the members of the committee had but a moment to escape by flight into the adjacent fields.

It was now perceived by Colonel Smith, who

† Mr. Loring was present on the Stage, at the delivery of this address.

commanded the British detachment, that the country, on all sides, was in a state of alarm. The news had spread in every direction, both by the way of Charlestown and Roxbury. The lights in the North Church steeple had given the signal, before the troops had fairly embarked. It was propagated by the alarm bell, from village to village; volleys from the minute-men were heard in every direction; and as fast as light and sound could travel, the news ran through Massachusetts, I might say through New-England; and every man as he heard it sprang to his arms. As a measure of precaution under these circumstances, Colonel Smith detached six companies of light infantry and marines, to move forward under Major Pitcairne and take possession of the bridges at Concord, in order to cut off the communication with the interior of the country. At the same time also, he sent back to General Gage and asked a reinforcement, a piece of forththought which saved all that was saved of the fortunes of that day. Before these detached companies could reach Lexington, the officers already mentioned were hastening down the road; and falling in with Major Pitcairne, informed him, that five hundred men were assembling on Lexington green to resist the troops. In consequence of this exaggerated account, the advance party was halted, to give time for the grenadiers to come up.

And thus, fellow citizens, having glanced at all the other movements of this memorable night, we are prepared to contemplate that, which gives interest to them all. The company assembled on this spot, and which had been swelled by the British officers to five hundred, consisted in reality of sixty or seventy of the militia of Lexington. On the receipt of the information of the officers and the movement of the troops, a guard had been set, as we have seen, at the house of Mr. Clark, the evening before. After the receipt of the intelligence brought by Revere, the alarm bell was rung; and a summons sent round to the militia of the place, to assemble on the green. This was done by direction of the commander of the company, Capt. John Parker—an officer of approved firmness and courage. He had probably served in the French war, and gave many proofs, on this trying occasion, of a most intrepid spirit. About two o'clock in the morning, the drum beat to arms, the roll was called, and about one hundred and thirty answered to their names;—some of them, alas—whose ashes, now gathered in that depository, invoke the mortal horrors of this day,—for the last time on earth. Messengers were sent down the road to bring intelligence of the troops; and the men were ordered to load with powder and ball. One of the messengers soon returned with the report, that there were no troops to be seen. In consequence of this information, as the night was chilly, in order to spare the men, already harassed by the repeated alarms which had been given, and to relieve the anxiety of their families, the militia were dismissed; but ordered to await the return of the other expresses, sent down to gain a knowledge of the movements of the enemy, and directed to be in readiness, at the beat of the drum. About half the men sought refuge from the chill of the night, in the public house still standing on the edge of the green;—the residue retired to their homes in the neighborhood. One of the messengers was made prisoner by the British, who took effectual precautions to arrest every person on the road.—Benjamin Wellington hastening to the centre of the village, was intercepted by their advanced party, and was the first person seized by the enemy in arms, in the revolutionary war. In consequence of these precautions, the troops remained undiscovered till within a mile and a half of this place, and when there was scarce time for the last messenger, Capt. Thaddeus Bowman, to return with the tidings of their certain approach.

Anew, the last alarm, is now given: the bell rings,—guns are fired in haste on the green,—the drum beats to arms. The militia, within reach of the sound, hasten to obey the call, sixty or seventy in number, and are drawn up in order a very short distance in the rear of the spot on which we stand. The British troops, hearing the American drum, regard it as a challenge, and are halted at the distance of one hundred and sixty rods to load their guns. At the sight of this preparation a few of the militia on the two extremities of the line, naturally feeling the madness of resisting a force outnumbering their own ten to one, and supposed to be near twice as large as it was, showed a disposition to retreat. Captain Parker ordered them to stand their ground, threatening death to any man

who should fly,—but directed them not to fire unless first fired upon. The commanders of the British forces advanced some rods in front of their troops. With mingled threats and oaths, they bid the Americans lay down their arms and disperse, and call to their own troops, now rushing furiously on,—the light infantry on the right of the church in which we are now assembled, and the grenadiers on the left,—to fire. The order not being followed with instant obedience, is renewed with oaths and imprecations,—the officers discharge their pistols—and the foremost platoon fires over the heads of the Americans. Not one falls, and John Munroe, standing next to a kinsman of the same family name, calmly observed, that they were firing nothing but powder. Another general volley, aimed with fatal precision, succeeds. Ebenezer Munroe replied to the remark just made, that something more than powder was then fired, as he was shot himself in the arm. At the same moment, several dropped around them killed and wounded. Captain Parker now felt the necessity of directing his men to disperse, but it was not until several of them had returned the British fire, and some of them more than once, that this handful of brave men were driven from the field.

Of this gallant little company, seven were killed and ten wounded, a quarter part at least of the number drawn up, and a must signal proof of the firmness, with which they stood the British fire.—Willingly would I do justice to the separate merit of each individual of this heroic band; but tradition has not furnished us the means. A few interesting anecdotes have, however, been preserved. Jedediah Munroe was one of the most distinguished by this circumstance, in following the field, he marched with his pursuit of the enemy to Concord, and the afternoon. Ebenezer Munroe, two wounds, and a third ball through William Todd, the second in command, was pursued by Major Pitcairne, on horseback, up the north road, with repeated cries to stop or he was a dead man. Having leaped the fence, he discharged his gun at his pursuer, and thus compelled him to turn to take flight. Robert Munroe was killed with Parker, Muzzy, and Jonathan Harrington, on or near the line, where the company was formed. Robert Munroe had served in the French wars. He was the standard-bearer of his company at the capture of Louisbourg, in 1758. He now lived to see, set up for the first time, the banner of his country's Independence. He saw it raised amidst the handful of his brave associates; also, that he was struck down, without living like you, venerable survivors of that momentous day, to behold it, as it dillies with the wind and scorns the sun, blast of heaven and of man,—at the head of the triumphant hosts of America! All hail to the glorious ensign! Courage to the heart and strength to the hand, to which, in all time, it shall be entrusted! May it forever wave in honor, in unassailed glory, and patriotic hope, on the dome of the capitol, on the country's strong holds, on the tented plains, on the war-torned top-mast. Wherever on the earth's surface, the eye of the American shall behold it, may he have reason to bless it. On whatever spot it is planted, there may freedom have a foot-hold, humanity a brave champion, and religion an altar. Though stained with blood in a righteous cause, may it never in any cause, be stained with shame. Alike, when its gorgeous folds shall wanton in lazy holiday triumph, on the summer breeze, and its tattered fragments be dimly seen through the clouds of war, may it be the joy and pride of the American heart. First raised in the cause of right and liberty, in that cause alone may it forever spread out its streaming blazony to the battle and the storm. First raised in this humble village, and since borne victoriously across the continent and on every sea, may virtue, and freedom, and peace forever follow, where it leads the way! The banner which was raised, on this spot, by a village hero,\* was not that, whose glorious folds are now gathered round the sacred depository of the ashes of his brave companions. He carried the old provincial flag of Massachusetts Bay. As it had once been planted in triumph, on the walls of Louisbourg, Quebec, and Montreal, it was now raised in a New England village, among a band of brave men, some of whom had followed it to victory in distant fields, and now rallied beneath it, in the bo-

\* Joseph Simonds was the ensign of the Lexington company on the 19th of April, 1775.

son of their homes, determined, if duty called them, to shed their blood in its defence. May Heaven approve the omen. The ancient standard of Massachusetts Bay was displayed for the confederating colonies, before the STAR-SPANGLED BANNER OF THE UNION had been sung to the breeze. Should the time come (which God avert), when that glorious banner shall be rent in twain, may Massachusetts, who first raised her standard in the cause of United America, be the last by whom that cause is deserted; and as many of her children, who first raised that standard on this spot, fell gloriously in its defence, so may the last son of Massachusetts, to whom it shall be entrusted, not yield it but in the mortal agony!

[From the Army and Navy Chronicle.]  
ENGINEER ORDER, NO. 4.  
ENGINEER DEPARTMENT,  
Washington, 22d May, 1835.

The Chief Engineer has again the melancholy duty of announcing, with deep regret, to the Corps of Engineers the loss of another highly meritorious brother officer, Brevet Major GEORGE BLANET, who died at Smithville, N. C. on the 15th inst.

As a testimonial of respect for the memory of the deceased, the officers of the Corps of Engineers, and of the Military Academy, are requested to wear the usual badge of mourning for thirty days.  
C. GRATIOT.

Capt. J. A. Phillips, 7th Infantry, relieved from his staff appointment as Assistant Commissary of Subsistence, and acting Assistant Quartermaster, at the Military Academy West Point, and ordered to join his company at Fort Gibson, 11th May, 1835.

2d Lt. Edward Deas, 4th Artillery, assigned to duty in the Commissary General's Department.  
Lt. W. W. Mather, 7th Infantry, relieved from duty at the Military Academy, after the June examination, and ordered to join his company.

**INDIFFERENCE OF THE AMERICAN PEOPLE TO HUMAN LIFE.**—We have had repeated occasions to express our conviction, that in this country, the comfort, safety, and life of man, when committed to the charge of steamboats, stage drivers, or builders, seem literally to be deemed of no moment. The most awful accidents, from all these sources, are of frequent occurrence, yet we never hear of any inquiry into the cause of them—or penalty imposed for the negligence, paramoury, or ignorance from which they almost always result. We subjoin two new instances of fearful interest, and venture to predict, that there will be no judicial investigation in either case.

[From the Wheeling Gazette of the 25th May.]  
**ANOTHER STEAMBOAT EXPLOSION—FORTY PERSONS MISSING.**—By the arrival at this port this boat Warsaw, Capt. Keat-  
tish intelligence, that the while stopping at Memphis, a New Orleans to St. Louis, in inst., burst her boiler, by persons were either killed or had been found on Thursday Warsaw passed. The pa-  
lly German emigrants, and his passengers in addition, f the Union. We have no his melancholy occurrence, I doubtless furnish them in a day or two.

**NEW-ORLEANS, May 15th.—Awful Catastrophe.**—The three story brick building on the south side of Canal street, and between Camp and Magazine streets, occupied as the Planters' Hotel, and kept by Charles Armstrong, fell to the earth last night at about half past two o'clock. Reports had lately been making in the lower story, and it is presumed that too much of the support had been incautiously cut away.

The hotel was occupied as an eating and lodging house, and, it is calculated, contained, at the moment of the dreadful accident, between sixty and seventy inmates. The billiard room, which had been very full till late at night, had closed only a short time before. A young gentleman who had left it but a few minutes before the fall of the building, states that he passed to the opposite side of the street, to his boarding house, went up to the gallery in front, where he heard three distinct and loud cracks, resembling the discharge of small cannon,

then a sound like an earthquake, as the mass fell, and for a moment after, one, and only one, appalling cry, as if by the united voices of the sufferers! The alarm was directly given to the citizens, the bells rung, and engine companies turned out.

**STEAMBOAT MAJESTIC.**—There are no authentic accounts yet, of the actual number of sufferers, by the explosion on board this boat. The St. Louis (Mo.) Republican, however, of 25th ult., thus accounts for the occurrence, and states generally the number injured:

The steamboat Majestic arrived at this port last evening from New Orleans. We are sorry to hear that the boat met with a deplorable accident, just as she was leaving Memphis. The Captain had given orders, that the yawl which had been alongside should be taken astern; and while the crew were engaged in this work, the passengers, of whom there was a large number, rushed to the starboard side of the boat.

A short time intervened; the Captain gave orders to "trim the boat," and as soon as it was done the starboard boiler collapsed. Forty passengers were more or less scalded, of whom eight had died when the Majestic left Memphis, and several others were not expected to survive.

All the cabin passengers escaped unharmd;—the injury was confined to those on deck. The second engineer was also badly scalded.

**NEW ORLEANS, May 20.**—The diseases annually prevalent on the river Mississippi and its numerous tributaries, are again becoming rife. All the cases of cholera that were said to have occurred in this city were limited to passengers on boats coming down the river, in various parts of which numerous cases are still found. But no cholera exists in New Orleans, except the cholera morbus, common in other places at this period. Cases of bilious fever indeed occurred within the past few days, but not to any extent, nor are they alarming.

The very great negligence of voyagers on our western waters, and the very little care taken of them by the commanders of boats, are sufficient to engender disease. Hence the real source of disease on the Mississippi. We have personally witnessed these causes and effects, and most indignantly give our testimony against this culpable carelessness.

Now the small pox has broken out, and rages from Memphis to Natchez, and thence to Natchitoches.

**WHALE LOST.**—Capt. Richards, of ship America, arrived at New London from the Pacific ocean on the 20th January last, fell in with, in lat 38 56 S. lon 46 W. the wreck of the Merrimack, Captain master, of Newburyport—had the appearance of being in the water about 50 days.

[From the Evening Post.]

**WEST**  
The Board of Visitation of the Secretary of the Visitation of the Cadets, was organized this day by Hgn. Peter Y. Daniel, of Col. W. C. Lyman, of G her present:

Rev. J. Cogswell, Connecticut.  
Hon. C. G. Ferris, John W. Hunter, Esq. Jno. A. Graham, LL.D., New York.  
Gen. W. T. Rogers, Hon. Calvin Rlyth, Wm. J. Leiper, Wm. C. Frazer, Esqrs., Phila.  
Hon. P. V. Daniel, Col. Heuli, Dr. E. H. Carmichael, Virginia.  
John Bragg, Esq. North Carolina.  
Col. Wm. C. Lyman, Georgia.  
Dr. E. S. Davis, South Carolina.  
Thos. J. Pew, Joseph Holt, Esqrs., Kentucky.  
Gen. Wm. Milroy, Indiana.  
Col. P. Martin, Alabama.  
Brigadier General Henry Atkinson, of the United States Army.

**MEXICO AND THE UNITED STATES.**—We learn from an authentic source, that the additional Article to the Treaty of Limits, between the United States and the Republic of Mexico, has been concluded and approved by the General Congress of Mexico, and in virtue thereof, the period within which the respective Commissioners of both nations should meet, and decide on the boundary between the two countries, has been extended to one year from the date of the exchange of the ratifications.  
—[Jour. of Com.]

A patriot of the Revolution has enclosed \$500 to the Editors of the Commercial Advertiser, for the American Colonization Society; remarking, that "at this late period of his life, he cannot serve his country in any manner so beneficially, as in aiding that Society, in their wise and philanthropic endeavors, by degrees, to free the United States from a great and growing evil, and in some measure, to compensate the present generation of black men, for injuries our ancestors have done them and their fathers."

At the latest date, the French Chamber of Deputies was engaged in debate on the abolition of Negro Slavery in the French Colonies. The number of slaves in them is two hundred and seventy-eight thousand. In reply to several of the orators, (April 22d,) the President of the Council (Duke de Broglie) said—

"The moment was critical—that a hazardous experiment was now trying in England, and that in the uncertainty of its result it was the duty of Ministers to be silent; as to act otherwise would endanger the success of the experiment which Government might one day try—he would not say when—he would bind himself to nothing."

**AMERICAN TEMPERANCE SOCIETY.**—This Society held its anniversary meeting on the 26th instant, in the Park street Church, Boston, before a numerous and highly respectable audience. The following notice of its proceedings, has been furnished for publication in this paper:

"The report, which was partially read by the Rev. Dr. Edwards, the Corresponding Secretary, surpassed, if possible, in interest, any of the previous reports of the society, by the same able hand. One of its great objects is to show, that *alcohol is a poison*, and that too of the most deadly character, and—under whatever name—that it is injurious to the constitution of men in health. The report, in a most satisfactory manner, explodes the common error, that alcohol exists in a state of nature: it shows conclusively, that it does not follow, because fruits and grains are proper for man, that alcohol, which is formed by fermentation, *being a process of decay*, is also proper. The report takes the ground throughout, that it is with intoxicating liquors, under whatever title, that the friends of temperance have now to contend: on this broad and tenable ground, that so long as those drinks are used as a common beverage, there can be no hope of emancipating the world from the sin of drunkenness.

The following are among the remarkable, and certainly very encouraging facts, set forth in this report:

There are State Temperance Societies in every State but one of the Union.

There are eight thousand local societies.

Four thousand distilleries are represented as having extinguished their fires.

Eight thousand merchants as having abandoned the immoral traffic; and

Twelve hundred American vessels now navigating the ocean without the use of alcohol.

It speaks in high commendation of societies formed in England and this country, on the principle of total abstinence from all that can intoxicate, and from Strong Beer, as having been more injurious in England, than even ardent spirit. After the reading of the report, several able addresses were delivered, all advocating the principle of total and entire abstinence from every kind of intoxicating drink, as a common beverage. Amongst other important resolutions, the following was unanimously adopted:

As it has been proved by the experience of thousands in the United States, of all classes of persons, and in all kinds of lawful business, that abstinence from the use of all kinds of intoxicating liquor, as a drink, is not only safe but salutary, and as this is the only course in which it can be rationally expected, that intemperate persons will ever be permanently reformed, and as the example and kind moral influence of the temperate, is the grand means of leading the intemperate to adopt and pursue a course so essential to their present and future good. Therefore, resolved,

That the more extensively this course is adopted by all classes in the community, and especially by all members of Temperance Societies, the more rapid will be the progress of the Temperance Reform,

and the more certain the prospect that drunkenness and its evils will cease."

In connection with this subject, the following facts derived from an authentic source, will not be deemed uninteresting.

**Temperance Items, connected with the Press.**—The *Temperance Recorder*, established a few years since by the New York State Temperance Society, for the purpose of persuading the whole community to abandon the making, vending, and drinking ardent spirit, has perhaps had a patronage beyond that of any paper ever published. Its list of subscribers at one time rose to 200,000, but in consequence of its silence relative to fermented drinks, its patronage fell off, so that at the close of the last year, the number was reduced to about 50,000.—At the last annual meeting of the State Society, it was unanimously resolved that this paper should take higher ground, and urge on all classes the entire abandonment of all intoxicating liquors as a beverage. This change in the course of the paper has restored it again to favor, the lists have now risen to 100,000 and over, and a thousand or more subscribers a day is a very common occurrence.

The American Temperance Intelligencer, a large sheet, is now on its second year, 60,000 are required to meet the demand.

Of the American Temperance Almanac, for 1834, 300,000 were circulated. 1835, 160,000, the printer could not furnish any more in time.

The Almanac for 1836 is now in press, and striking off at the rate of 5000 to 6000 per day.—About 600,000 are already ordered.

Messrs. Talbot, Oliphant & Co. of this city, have offered to the Domestic and Foreign Missionary Society of the Protestant Episcopal Church, a free passage to China for their recently appointed Missionaries, the Rev. Messrs. Hanson and Lockwood, in the ship Morrison shortly to sail for Canton.

This is not the first, by many instances, in which the liberality of Commerce has, by these gentlemen, been made to advance the highest interests of civilization and religion. In this particular instance, it is marked with the most catholic spirit, for these gentlemen do not belong to the Episcopal Church.

**A PARENT'S LOVE.**—It is sometimes deemed by the cold-hearted, a mere rhapsody, to say of a parent's love, that it is stronger than death. In the affecting incident, however, related in the annexed paragraph, cut from the Bath (Steuken Co.) Advocate, the whole truth of that sentiment is most abundantly verified. "I cannot see him perish" are words that will find an echo in the heart of every parent, and sympathy in the bosom of all, who do not degrade the name and nature of man.

[From the Bath Advocate of 27th May.]

**DISTRESSING INCIDENT.**—Mr. Aaron Sium, with his family, consisting of a wife and five children, on their way from Cherry Valley, Otsego co. to Allegany co. took passage on a boat on the Crooked Lake to Hammondsport, on the 20th instant.—While passing up the Lake, a little son, aged five years, accidentally fell overboard. After a moment's pause, the father exclaimed, "I cannot see him perish," and immediately plunged in after him. The sails were lowered, but it was impossible to check the progress of the boat in time to save them, and both immediately sunk—leaving an afflicted widow and remaining children in a land of strangers destitute of all means of support, except from the hand of charity. Mr. S. had in his pocket all the money they possessed.

With praiseworthy effort and liberality the citizens of Hammondsport afforded sufficient means to make them comfortable.

The Annapolis Republican of Saturday has the following additional particulars of the interesting incident which occurred in the harbor of that city last week:—

A party of pleasure, including the family of Col. Wallach, Commandant of Fort Severn, embarked on Monday last, and after spending a delightful day upon the water, rambling over the beautiful green banks of the Severn, and partaking of a repast upon the shores of the Round Bay, the schooner was returning with the party in the evening, when a sudden flaw of wind struck her—the main boom jibed, and carried one of the young ladies overboard. Quick as thought, Lieut. J. J. B. Wal-

bach, of the United States Navy, plunged into the river to save her. The spring by which he designed to throw himself as near as possible to her, owing to a sudden career of the vessel, was the means of plunging him to a great depth. When he rose, the object of his anxiety was no longer to be seen. Nearing the spot, however, she was discerned sinking below the waves. On being brought up, she very naturally clung to the only object within reach, for safety, but unfortunately in such a manner as to deprive him of the power of motion, necessary to keep above water. In a short time, both sunk together.

Rallying his strength, with an effort, he rose again with his fair charge, and not only sustained her long enough for her to breathe afresh, but with the utmost presence of mind, made dispositions to keep afloat; but entangled with clothes, and disbled from motion, his buoyance soon, of course, became exhausted, and both again disappeared.

It occurred to Lieut. W. as he sunk, to endeavor to reach the bottom, in order to obtain an impetus for re-ascending, but the depth was found too great, there was 24 feet water. It was probably with the last remains of strength that another exertion enabled him once more to regain the surface with his fair companion. But they soon sunk again. His brother, Lieut. Augustus B. Walbach, of the United States Army, who had been at the head of the boat when the accident occurred, on perceiving those overboard, springing into the river, reached the parties at this critical moment. In the act of bringing them up to the surface, the young lady insensibly placed her hand upon his head, so as effectually to keep him under water. In this position, however, he retained his presence of mind, and by swimming under water with his brother's hand upon his shoulder, contrived to sustain both for a considerable time, and to them all, a most eventful space.

All three however, became exhausted, and had sunk a full arm's length when the captain of the schooner, having succeeded in rounding his boat to, and launching a small crazy punt from her deck, arrived just in time to reach one of the party, and thereby bringing them all up to the surface.—The first breath of returning life in the young Naval Officer, was to sing out a direction to the raw hands thus left to manage the schooner, and which was now at considerable distance to 'haul that jib to windward, and put down the helm.' One of the officers laying hold of the little boat on one side, and the other on the other, they contrived to steady it so that the Captain could draw the lady on board without capsizeing it—and in that posture they were paddled to the schooner and received on board.

[From the Western Carolinian.]

**DREADFUL TORNADO.**—We learn that a very destructive tornado passed over a part of this county on Saturday, the 9th May, near the section known as the Jersey Settlement. It prostrated every thing before it, not a house, tree, or fence was left standing where it passed. The destruction of property was very great; but the most melancholy circumstance was the death of a respectable young lady, whose name be believe, was Jones. She was standing in the corner of the house when it tumbled down and crushed her to death; when she was found, after the storm subsided, her head was severed from her body! We have not learned the extent of the tornado, but it embraced in width about a quarter of a mile.

[From the National Gazette.]

A letter has been received, per ship Liberty, from H. Piddington, Esq. Foreign Secretary of the Asiatic Horticultural and Agricultural Society, dated Calcutta, Dec. 24, 1834, and addressed to Dr. R. Harlan, announcing the following interesting discovery—

"You will learn, too, with pleasure, I doubt not, the splendid discovery of a country on the N. E. frontier, or the N. E. corner of Assam, in which, through forests of thirty days march the true Tea Plant abounds. This province, too, borders on that of Yumar in China, in which the plant is cultivated for consumption and sale. We have also had the flower and fruit sent down to Dr. Wallach, of the Honorable Company's Botanic Garden, who pronounces it to be the true tea plant; and who is, as you may well suppose, much gratified with the discovery. These facts are contained in a letter which I have just received from Dr. W. This discovery will perhaps cause a great revolution in the tea trade in a few years."

Was Mr. Rives, the founder of the French monarchy after the 3 days revolution? This question will not appear wholly without purpose, when the annexed paragraph from the London Times, is considered, and when it is known, that the substance of what is therein stated, has been frequently before alluded to.

Will not Mr. Rives, think it worth his while to give some explanation of his imputed agency in this matter?

[From the London Times.]

PARIS, April 18.—Among all the fabrications retained in the Chamber and the newspapers on the subject of the American claims, and the treaty which reduced them to the form of a liquid obligation, it is a matter of surprise, especially to the members of the diplomatic body, with whom the fact is familiar, that neither deputies nor journalists have laid their hands on an anecdote, which would have thrown more light on the chief point at issue, than all that has resulted from a fortnight's incessant debate. During the first days of the revolution, when the future King of the French was still at Neuilly, and Lafayette was hesitating at the Hotel de Ville between the proclamation of the Republic, and the institutions of a monarchy surrounded by republican institutions, the Duke of Orleans sent across the barricades, to ask an interview of Mr. Rives, the American Minister; who, like most of the diplomatic servants of the United States, is known to have entertained opinions on the subject of government, having a decided leaning towards aristocratical and monarchical forms. The object of his Royal Highness was to induce Mr. Rives to go to the Hotel de Ville, and convey to Lafayette the effect of his own conviction on the all important question which was then under deliberation. The American Minister consented, and during his subsequent stay in Paris, as perhaps now at Washington, he delighted to recount the part he played at this crisis of the revolution, putting especial emphasis on the cordiality with which he was received by the venerable old man, who for the moment held the destinies of France in his hands, because in the representative of the American Republic, Lafayette thought he saw the personification of that pure form of government with which he desired that his country might be endowed. Suffice it to say, that the mission proved successful, that Lafayette allowed himself to be convinced, and that Mr. Rives knew how to exact from the King and his Ministers the price of that intervention, which had contributed so essentially to smooth his path to the throne.

For late papers from the Island of Jamaica, (Kingston dates of the 15th ult.) we are indebted to Mr. Gilpin of the Exchange reading rooms—in which, by the bye, we may say en passant, merchants, strangers, and others, will find every accommodation usually looked for in such a place.

The Governor of Jamaica, Lord Sligo, has just returned from the Caymanas, where he had been to announce to the proprietors that by reason of their slaves not having been registered within the time prescribed by the emancipation act of the British Parliament, they had become unconditionally free. The error or omission was the fault of Parliament, and not of the proprietors, and yet the latter bear the loss. They submitted at once to the decision, reserving to themselves the right of appealing to Parliament for an indemnity for the loss which they thus sustain, while the planters of Jamaica and other Islands, are permitted to require apprentice labor from their former slaves.

Jamaica was quite tranquil; but it seems to be feared in some neighborhoods that the apprentices system will not enable the planters to keep up any thing like their former supply of sugar. About the coffee plantations less solicitude is expressed; indeed, it is avowed, that the coffee may be cultivated without difficulty by European emigrants.

**FEARFUL EARTHQUAKE.**—The New Bedford Mercury of yesterday contains the following account of the effects of a most fearful Earthquake, in Chili, on the 20th Feb. last.

**LATE FROM CHILI.**—Destruction of the city of Concepcion and Talcahuana, by an Earthquake.—We learn by Capt. Whitton, of the ship Coral, at this port, 85 days from Talcahuana, the melancholy

ly intelligence of the entire destruction of the city of Concepcion and Talcahuana by an Earthquake on the 20th February. The following statement was drawn up by a gentleman who was an eye witness:—

"The morning of the 20th was clear and serene, but it will prove an ever memorable day to the miserable people now inhabiting the border hills in this vicinity. The first shock commenced at 20 minutes past eleven o'clock, and lasted with but slight intermission for 47 minutes; causing the hills and valleys to rise and fall like the waves of the ocean. During the continuance of the first shock, which was much the most severe, I expected to be destroyed every moment—it was almost impossible to keep upright.

Talcahuana is completely demolished—the buildings were not only shaken down, but the ruins of houses, stores, &c. were completely swept away afterwards by the sea, which retired about 15 minutes after the first shock, leaving the shipping entirely dry, at anchor in the harbor—it came in again in about two minutes, to the height of 25 feet above the usual mark, overwhelming the whole place. Men, women, and children fled for the mountains, but many were overtaken and swept to the ocean, by the receding waves, which completed the entire destruction of the town, depriving hundreds of people of their second garments—many who were in good circumstances are now completely destitute. Furniture of all kinds was carried away with the houses; not even leaving a vestige to inform the owner of the situation of his former residence. It would require an eye witness to be made acquainted with the complete destruction of the town by this awful calamity.

Concepcion, a city containing about 25,000 inhabitants, is one complete heap of ruins; the houses being built chiefly of brick. *There is not one solitary building left standing within the limits of the city, and for leagues round.* The shock came from a southeast direction, and in its way destroyed every thing. A number of small towns have been heard from—Chilian, Salea, Armadecan, Lingus, Enivas, Peusul, St. Carlos, Vallaya, and Arnyles, were destroyed.

The number of lives lost could not be correctly ascertained. A new cathedral building in Concepcion, buried twenty workmen in its ruins. There were but two American ships in the harbor of Talcahuana at the time, besides the Coral—the Milton and the Nile. A small schooner was driven from her anchoring and drifted over the town."

Chili has been subject to earthquakes ever since its settlement by the Spaniards. The city of Concepcion was originally built three leagues to the north of its present site, but having been twice destroyed by earthquakes, the inhabitants removed to the south and built the city on its present location. Concepcion is represented by those who have visited it as a delightful place—the inhabitants high minded, and honest in all the relations of life. A number of Americans, principally mechanics, have located themselves in the city. Talcahuana, situated in lat. 36 42 N., lon. 83 06 E., being the port of Concepcion, and a place of considerable business. It has been the general resort of American whale ships for several years past—the harbor being one of the best on the coast. The town is situated almost on a level with the sea, large hills rising in the rear. The inhabitants, when the Coral left, were in a most deplorable situation.—Captain Paul Delano, who is known to many of our citizens, and to every one who he visited Talcahuana, has lost his little property, and was compelled to take shelter on board the shipping—his beautiful residence, the home of our countrymen, whether in prosperity or adversity, is completely swept away, and himself and lady narrowly escaped with their lives. No individual, not holding an official station from our government, ever rendered more substantial benefit to his countrymen than Captain Delano. Many of the perplexing and useless revenue laws of the country have been repealed through his instrumentality. Mr. Andros, an honest and honorable gentleman, who has done the supplying agency-business of late years, for whale ships, lost all his property.—

The view from the shipping in the harbor during the different shocks, is represented by an eye witness as awfully grand and terrific.—The unusual trembling and agitation of the ship—the convulsions and heavings of the mountains and plains, as far as the eye could extend—the sight at a distance of the inhabitants, fleeing, they knew not whither, in safety—the violent rushing of the waters over

the ruins of a thickly populated town, sweeping the wrecks of the demolished habitations of the rich and poor, into one common chaos of ruin, was calculated to impress deeply the mind of the beholder.

**VOLCANOE.**—Several weeks previous to the first shock of the late destructive earthquake at Concepcion, two large volcanoes burst out on the southern ridges of the range of mountains known by the name of the "Cordilleras," and at the last accounts continued to emit large volumes of smoke and lava to the terror of the inhabitants of the neighboring provinces.

We yesterday perused a letter from Captain Paul Delano, dated Talcahuana, giving the particulars of the destruction of that place. We find no facts of importance in addition to those published yesterday. The destruction of towns and villages extended sixty miles in the interior.—[New Bedford Mercury, of yesterday.]

Brig Panope, Doane, reports that the American Consul, THOS. WOOLDRIDGE, Esq. died suddenly at Matagorda, on the evening of the 24th April, of apoplexy. He had been on duty but a short time.

**BALLOON ASCENSION.**—Mr. Zebulon Mitchell happily effected his ascent yesterday, from the Old Council Chamber Hill, according to agreement.—The day was uncommonly fine for the experiment, and a very respectable number of citizens assembled to encourage and patronize the sciences, witness the interesting process of generating hydrogen gas, and obtain a knowledge of chemistry.—Mr. Mitchell had advertised to take his station in the car at 4 o'clock. Some ten or fifteen minutes after that time having elapsed, without exhibiting him to the non-paying customers outside of "the Amphitheatre," who cared nought for chemistry, and came merely to see the sight, they began to grow restive, and judging, perhaps, from the gaunt appearance of the balloon, that there was to be a failure they proceeded albeit, very peaceably, to pull down some twenty yards of the fence which obstructed their view. This disclosed the car already occupied by the Aeronaut, who to satisfy them that all was right, directed those who held the cables to proceed through the breach. Having floated in this manner to some distance along the verge of the hill, he cut loose and ascended, doffing his hat, waving his flag, and scattering his verses in the approved style on such occasions. The breeze carried him in an easterly direction—in which he was proceeding when we last saw him.—Every thing was favorable for an ascent to a great height, except that the aerostat was not sufficiently inflated.—[Rich. Whig.]

[From the Boston Courier of yesterday.]

MR. LAURIAT'S BALLOON went off yesterday afternoon,—but he did not go with it, wisely preferring, no doubt, to remain on terra firma among his fellow-mortals, to contending with the powers of the air. We are not able to state what was done in the amphitheatre, where there seemed to be an immense crowd; we only made one of thirty or forty thousand spectators who watched the progress of the balloon after it rose above the enclosure.—Judging from the appearance, it was not more than half inflated.

[From the Salem Gazette.]

**AEROSTATION.**—Balloon mad, as this generation is, the aerostats of the present day tax our credulity less than those of a past generation. In 1796, citizen Campernas, a French hydraulic Engineer, wrote a long letter to Napoleon Bonaparte, then General in Chief of the army of Italy, from which we extract a paragraph or two. By the letter of Campernas, it appears that his plan had been examined by a Committee of the National Institute, who testified their approbation in a long report, extracts from which accompany the letter:—

**Citizen General.**—

The artist who addresses you, filled with the most lively gratitude, will erect, if the means of execution be afforded him, a vast edifice, whence, at the conclusion of his labors there will issue an Aerial Vessel capable of carrying up with you more than 200 persons, and which may be directed to any point of the compass. I myself will be your pilot. You can thus, without any danger, hover above the fleets of enemies jealous of our happiness, and thunder against them like a new Jupiter, merely by throwing perpendicularly downwards firebrands made of a substance which will kindle only by the contact and percussion at the end of its tail, but which it will be impossible to extinguish.

Or perhaps you may think it more prudent to begin at once by forcing the British cabinet to capitulate, which you may easily do, as you will have it in your power to set fire to the city of London, or to any of the maritime towns of England. From the calculations I have made, I am convinced that with this machine you may go from Paris to London, and return back again to Paris in twenty-four hours, without descending.

The object I propose is to establish in the great ocean of the atmosphere a general navigation, infinitely more certain and more advantageous than maritime navigation, which has ever disturbed the tranquillity of mankind—to restore the perfect liberty of commerce, and to give peace and happiness to all the nations of the universe, and unite them as one family. By great labor I have surmounted the multiplied obstacles which presented themselves before me, and my progressive discoveries are developed in a work which I have prepared, consisting of about 400 pages, and divided into five parts.

#### RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, in advance. Previous volumes same price. Full set of four volumes, \$12.

#### RAILROAD AND CANAL MAP.

Or a Map of the United States, 34 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$2.

#### MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is extracted from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, in advance. Previous volumes \$1.50 each.

#### 'S COMPANION—

in octavo form, of sixteen to persuade APPARENTLY INDUSTRY, TEMPERANCE, &c. at the office of the No. 35 Wall Street, New York, for 12 numbers—D. K. MINOR.

Single paid. Eleven numbers, \$2.—and twenty—D. K. M.

#### NEWS for \$10.

#### NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE, &c. however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

#### QUARTERLY JOURNAL OF AGRICULTURE, MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading these advertisements. It has been published in \$5, but will be, hereafter, at \$1 per annum—always in advance; each quarterly number to contain about 120 pages.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; F. Wenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,  
35 Wall street, New-York.

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thorough printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-1

#### PUBLIC NOTICE.

THE undersigned, Commissioners for the amelioration of the navigation of the Richelieu or Chamby River, will receive at their office, in the borough of St. Denis, on the 15th of June next, sealed propositions for the construction or erection of a Dam or Causeway, with a Lock, to be erected about three miles above the village of St. Denis, either by Cut Stones, Common Stones, Pierres Brutes, or in Wood, according to the plans and specifications made by W. R. Hopkins, Esq., Engineer, deposited, and where they can be seen at any time, in the hands of Joseph Cartier, Esq., one of the said Commissioners, at St. Antoine.

All propositions addressed by the mail must be sent free of postage. Two good securities will be required for the due execution of the above works.

Further information can be had at any time, from the undersigned, in addressing them at their respective residences, or from the said W. R. Hopkins, Esq., at the Hotel, at the Chamby Basin.

Rocher St. Denis, at St. Denis.  
Joseph CARTIER, at St. Antoine.  
Jm. T. DROLET, at St. Marc.  
L. C. HUVERT, at St. Charles.  
L. F. DESCHAMBAULT, at St. Denis.

Office of the Commissioners, at St. Denis, May 11, 1835.

The above Dam and Lock are in dimensions as follows: Lock 250 feet, Chamber 50 feet wide; Dam 45 feet long, 8 feet high.

#### RAILROAD CASTINGS.

MARY & WARD, Proprietors of the Albany Engine Air Furnace and Machine Shop, will make to order castings, chimes and keels, and every other description of castings required for railroads. R-ly 1834

#### STEPHENSON.

Builder of a superior style of Passenger Cars for Railroads.

No. 204 Elizabeth street, near Blocher street, New-York.

RAILROAD COMPANIES would do well to examine these Cars, a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J-ly

#### NOTICE TO MANUFACTURERS.

35 NIXON FARMER, of the village of Lansingburgh, in the county of Rensselaer, and state of New York, has invented and put in operation a Machine for making Wreath (Railroad) square points. This machine will make at least eight feet, and about forty feet in length, and in the same proportion larger sizes, as may be required. The machine is simple and comes from the machine completely heated and red-hot, that its capacity for being clenched in good and safe power is increased to drive one machine, and be applied where such power is driving machinery. Said Farmer will make, send a machine, or send, to any person who may pay as soon as they may be made, and on the most terms. He also desires to sell one half of his for the use of said machines throughout the U. S. Any person desiring further information, or will please to call at the machine shop of Mr. Carey, in the village of Lansingburgh. August 1, 1835.

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes, a Nail, from 3 to 18 inches manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England), where the subscriber obtained a Patent, are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having one corner beveled suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroad now in progress in the United States are furnished with Spikes made at the above named factory for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

Troy, N. Y. July, 1831

Spikes are kept for sale, at factory prices, by I. & J. Wood, Albany, and the principal Iron Merchants in Albany and Troy. J. I. Brown, 222 West street, New-York; A. M. Jones, Philadelphia; T. J. Janssens, Baltimore; DeGrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of examining the manufacture and to keep pace with the daily increasing demand for his Spikes.

1835

H. BURDEN.

HERBERT BURDEN, Agent.

#### RAILROAD CAR WHEELS AND ROPS, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and bent to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPKINGS.

Also, Flange Tires turned complete.

ROGERS, KETCHUM & GROSVENOR

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be as superior to any thing of the kind now in use. Ship and Boat Spikes made (all sizes) under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS STARK, at the Factory, Troy, N. Y. Sept. 15 by

#### RAILWAY IRON.

36 tons of 1 inch by 1 inch,	Flat Bars in lengths of
100 do. 1 1/2 in. do.	14 to 15 feet, counter sunk
40 do. 1 1/2 in. do.	holes, ended at an angle
300 do. 3 in. do.	of 45 degrees, with ap-
300 do. 3 in. do.	pling plates and nails to
soon expected	suit.

330 do. of Edge Rails of 30 lbs. per yard, with re-

quisite chairs, keys and pins.

Wrought Iron Pins of 30, 35, and 36 inches diameter

for Wheels of Railway Cars, and of 60 inches diameter

for Locomotive wheels.

Axles of 24, 26, 28, 30, 32, 34, and 36 inches diameter for

Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Govern-

ments and for the use of Government, and the Drawback

taken in payment. A. & G. BALSTON.

8 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails,

Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use

both in this country and Great Britain, will be exhibited to

those disposed to examine them. 871 count

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality

warranted.

Leveling instruments, large and small sizes, with high

magnifying powers with flanges made by Troughton, to-

gether with a large assortment of Engineering Instru-

ments, manufactured and sold by

E. & G. W. BLUNT, 134 Water street,

corner of Maiden lane.

331

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instru-

ments in his profession, warranted equal, if not superior,

in principles of construction and workmanship to any im-

ported or manufactured in the United States, several of

which are entirely new among which are an Improved

Compass, with a Telescope attached, by which angles can

be taken with or without the use of the needle, with per-

fect accuracy—a Railroad Gauge, with two Tel-

escopes—and a Leveling Instrument, with a Telescope

attached, particularly adapted to Railroad purposes.

WM J. YOUNG.

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully sub-

mitted to Engineers, Surveyors, and others interested.

Balt. more, 1837.

In reply to the inquiry respecting the instruments man-

ufactured by them, now in use on the Baltimore and Ohio

Railroad, I cheerfully furnish the following state-

ments. The whole number of Levels now in possession

of the department of construction of this road is seven

The whole number of the "Improved Compass" is eight

These are all exclusive of the number in the service of the

Engineers and Graveling Department.

Both Levels and Compasses are in good repair. They

have been repaired but little repairs, except from accidents

to which all instruments of the kind are liable.

I have found that the patterns for the levels and com-

passes have been preferred by my associates generally, to

any others in use, and the Improved Compass is superior

to any other description of Compass that we have yet

tried in laying the rails on this Road.

This instrument, more recently improved with a re-

volving telescope, in place of the vane sights, leaves the

engineer scarcely any thing to desire in the formation or

convenience of the Compass. It is indeed the most com-

pletely adapted to lateral angles of any angle and cheap

instrument that I have yet seen, and I cannot but believe

it will be preferred to all others now in use for laying of

rails—and in fact, when known, I think it will be as highly

appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLE, Sup't of Construction

of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of

Mr. Young's Patent Improved Compass, I can safely

say I believe it to be much superior to any other instrument

of the kind, now in use, and as such most cheerfully re-

commended to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Overminton, February, 1833.

For a year past I have used instruments made by Mr.

W. J. Young, of Philadelphia, in which he has combined

the properties of a Theodolite with the common level.

I consider these instruments admirably calculated for

laying out Railroads, and can recommend them to the

notice of Engineers as preferable to any others for that

purpose.

HENRY E. CAMPBELL, Esq. Philad.

and by

German and Morris, Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JUNE 13, 1835.

**RAILROAD LOCKS.**—We publish to-day another communication from "M," upon this novel, and yet very important, subject. It does not yet seem to arrest the attention of engineers. They will not, we hope, let it pass without a word of comment.

**NEW MOTIVE POWER FOR RAILROADS,** is the title of an article published in this number of the Journal, from the Richmond (Va.) Compiler. It is a suggestion well worthy of attention, which it will doubtless receive in these days of experiments.

**BLOSSBURG AND PAINTED POST RAILROAD.**—In our columns to-day will be found the notice from the Commissioners, for opening the books for subscription to the Stock of the above Railroad. With its characteristic liberality, the Pennsylvania Legislature has guaranteed a dividend of 5 per cent. for 20 years, on the Stock of this work; and from the information contained in the report of the Engineer, Richard C. Taylor, Esq., we have not a doubt that the dividend will be much greater, as the vicinity of Blossburg abounds with an inexhaustible supply of bituminous coal, equal to the best Liverpool, and the route for the road is uncommonly feasible, running the entire distance upon the banks of the Tioga or Chemung river. Considering the unbounded market for this coal, and the outlet for an immense quantity of lumber, we think the Legislature of Pennsylvania could very safely say that the Stockholders should receive 5 per cent. interest.

**NEW JERSEY RAILROAD AND TRANSPORTATION COMPANY.**—The following gentlemen have been unanimously elected Directors of the New Jersey Railroad and Transportation Company for the ensuing year:

John S. Darcy,	Ashbel W. Corey,
William W. Woolsey,	George P. Molleson,
Thomas Sates,	George L. Schuyler,
Elihu Townsend,	John P. Jackson.
Anthony Dey,	

At a subsequent meeting of the Board, the following appointments were unanimously made:

Gen. John S. Darcy, President.
Elihu Townsend, Treasurer.
John P. Jackson, Secretary.
William Pennington, Attorney and Counselor.

A. W. Corey, Esq. having declined the situation of Superintendent, in consequence of ill health, George L. Schuyler, Esq., was unanimously appointed to succeed Mr. Corey as Superintendent.—[Newark Daily Adv.]

**CHESAPEAKE & OHIO CANAL COMPANY.**—We have received the seventh annual report of the Directors of this Company, which was made to the Stockholders by the President, George C. Washington, on Monday last. It is a well written paper, and presents the affairs of the company clearly and succinctly.

We gather from it that a continuous canal is now opened for navigation 110 miles from the basin, in Washington, to 8 miles above Williamsport.

The entire cost of the canal, including all expenses, is estimated at \$4,300,590.

The canal from Georgetown to Little Falls is 80 feet wide at the water line, and 7 feet deep; and to Harper's Ferry averages full 80 feet in width and 6 in depth; from that point to eight miles above Williamsport it is reduced to fifty in width and 6 in depth, and will retain the same proportions to Cumberland.

There are no obstructions on the canal to prevent the free passage of steamboats; the only permanent bridges being at an elevation of 17 feet above the water line.

There are 59 locks; and the elevation of the canal so far as completed is 353 feet.

There are 5 aqueducts, all constructed of solid masonry; and 138 culverts.

The canal is fed by five dams. They are constructed on the most approved plans, of the best materials, and give promise of great strength and durability.

Engineers are now locating the line of the canal to Cumberland.

Experiments are now being made to test the practicability of navigating the canal with steamboats. As yet nothing definite has been ascertained, but the Directors do not despair of ultimate success.

The revenue of the canal is improving, and its early completion to Cumberland, and consequent advantages to the stockholders and the state, will be looked forward to with momentous interest.—[Balt. Chronicle.]

The following statement, relative to the South-Carolina Canal and Railroad Company, has been furnished us, which we cheerfully lay before our readers.

At a meeting of the Stockholders of the South-Carolina Canal and Railroad Company held at their office, 7th of April, 1835—John Ravenel, President, in the chair—

The following Report from the Committee on Accounts was read:

Agreeably with a resolution of the Board passed on 20th March last, requesting the Committee on Accounts to report upon the debts and liabilities of the Company, and to suggest such means as they may deem proper to meet the same, and other necessary expenditures on road and machinery, the following is submitted to your consideration:

By the accompanying statement of the affairs of the Company made up to the 1st instant, the debts (exclusive of the Loan of \$100,000 from the State and interest due thereon to 3d March, 1835), amount to \$216,523 67

It is also liable for the following work under contract and now progressing, to wit:

For 6 locomotives under construction in Liverpool, by R. Stephenson & Son, delivered on the road,	\$1,800 00
Do. 2 do. do. by Eason & Dotterer, Charleston,	11,500 00
Do. 8 tenders do. at the depositary (a portion of materials being already provided),	1,800 00
Do. 150 burthen cars do. do.	31,000 00
Do. duplicates ordered from England,	1,940 00
Do. blacksmith shop, house for engines and cars, and additional tracks, at Hamburg,	2,000 00
Do. buildings at Aiken for engines,	900 00
Do. turnout to be constructed,	1,000 00
Do. fences, and alterations to depositories,	500 00

Making a total of - \$398,773 67

The contractors of the greater part of the above enumerated machinery being bound to deliver, under penalty, your Committee believe that on the 15th October next the available power and means for business will be as follows, to wit: 22 locomotives, 400 burthen cars, 21 passage do., 7 baggage

do. This provision is estimated as equal to three freight trains of 12 to 14 cars each, and one passenger train, daily, from each end of the line, leaving 5 reserve engines; and will enable the Company to transport, annually, 149,000 bales of cotton down at \$1 per bale, and 28,440 tons of freight up at \$10 per ton; which would amount to \$533,440—passage and mail money not included.

But as the capacity (as above calculated) will probably exceed the business offering, the following is submitted as an estimate, below which we will not fall for the year to commence the 15th of October next, to wit:

60,000 bales of Cotton, at 75 cts.	
per bale, - - - - -	\$46,000 00
12,000 tons of freight up, at \$10	
per ton, - - - - -	120,000 00
Passage money, - - - - -	100,000 00
Mail money, - - - - -	10,000 00

Making the probable total receipts, - - - - -	\$275,000 00
From which deduct the following expenses:	
For current expenses upon the business of the road, - - - - -	\$130,000 00
Do. embankment, 15,000 00	
Do. new machinery, 30,000 00	
	175,000 00

Leaving a balance of nett profits, - - - - - \$100,000 00 if the debts were paid. In confirmation of the above estimate, we beg to bring to your view, that for the year which ended on the 1st instant, the receipts were \$183,974 07—the work having been done by an average force not exceeding 7 locomotives and 125 burthen cars, under numerous disadvantages. Notwithstanding our liability to be misled and the frequent disappointments attendant upon calculations of this kind, in the view of your Committee, an equipment so full in machinery and other means as will be ready by the 15th October, and the daily improvement of the road by the progress of the work of embankment, authorize the belief that we shall then be prepared for every probable exigency. And that the capacity, usefulness, and value of the road, are about to be fully and permanently established. With such prospects, it is deemed the true interest of the Stockholders to pay the debts of the Company—to relieve it of the numerous disadvantages of daily financial arrangements—and, without delay, to place it in a situation which will command public confidence, and give to the stock its true value. To do this, two modes have been suggested. The first is the consolidation of the debts by the issue of bonds, redeemable at eight, nine, and ten years, and bearing interest at the rate of 6 per cent. per annum, payable quarterly.

The second is, the increase of the capital stock by the sale of 3000 shares at \$100 per share, on the following terms, to wit: \$10 payable at time of subscription, 10 do. on the 20th July, 10 do. on the 20th October, and 10 do. monthly afterwards, until the whole be paid. The said shares to be entitled to any dividend that shall be made after July next: provided they shall have been paid up in full on or before the 20th of October—the Stockholders, when the books shall be opened, to have the preference for two days only. If more stock be then subscribed than three thousand shares, the whole shall be divided among the subscribing Stockholders, *pro rata*, as to the number previously held by each.

To the first, or the issue of bonds, it is objected, That it will not improve our situation, inasmuch as we shall still be in debt, and under all the disadvantages of being so: for companies, like individuals, are mistrusted or confided in, as they are understood to be indebted or otherwise. Nor would it be fair to argue from the comparatively few instances of those who have found advantage in being in debt, as they are exceptions to the general rule. If the public mind could always know the real situation of a company, its means and prospects, as well as its debts, the stock would not be liable to undue depression, and the interests of the Stockholders would not suffer; but the fact is generally otherwise, and with the idea of debt is associated the disadvantages that commonly attend it. In the case under consideration, the debts of the Company are believed to work direct injury to the Stockholders by affecting public confidence and consequently the value of the stock.

2nd. That the interest to be paid will then be taken as it now is, from the receipts of the road, and of course will continue to diminish, as it now does, the dividends. While Stockholders would be paying a higher rate of interest on the bonds, than many of them receive from their capital otherwise invested, not only transferring the advantages of a good investment to those who may lend upon said bonds, but permitting their property to remain under the depression believed now to result from its being encumbered with debt.

3rd. The improbability of obtaining here, or elsewhere, the amount necessary to accomplish our purpose at the proposed rate of interest.

The second proposition, viz. the increase of the capital stock, appears in all respects advisable. If our estimate of receipts be fair, and we believe it fully to be so, they will be equal to 8½ per cent. annually on \$1,200,000, or 12,000 shares.

The present number of shares is 9,000. Your Committee, therefore, recommend the sale of 3,000 shares of additional stock, which will produce \$300,000, and pay the existing debt and contracts of the Company, as previously stated, except that to the State of \$100,000, which not being due until the 7th April, 1857, and being at the rate of 5 per cent. per annum, it is deemed inexpedient to include in the proposed provision.

JOHN RAVENEL,	} Committee on Accounts.
JOHN HARLETT,	
GEORGE GIBSON,	
WILLIAM DAVIDSON,	

On motion of Mr. John Robinson, seconded by Mr. D. Perkins, Resolved, That the Report with its recommendations be adopted; and that the Board take measures to carry the same into effect.

Extract from the minutes.

JOHN T. ROBERTSON, Secretary.

At a meeting of the Direction of the South-Carolina Canal and Railroad Company held on 7th April, 1856.

Resolved, That the books be opened for Three Thousand Shares of additional stock to the Stockholders only on the 27th and 28th of April, and should they not take up the whole on those days, then the books to be opened to the public on the 29th instant, for subscriptions on the terms prescribed in the recommendations of the Report adopted by the Stockholders.

Extract from the minutes.

JOHN T. ROBERTSON, Secretary.

The \$200,000 dollars, we are informed, have been subscribed. The old stock is

current at 109, and the new scrip at 106½: showing, conclusively, that those who have borne the heat and burthen of the undertaking, and who are, it is to be presumed, familiar with its condition and prospects, have full confidence in the success of the road.

(For the American Railroad Journal.)

#### Remarks on the Substitution of Locks for Inclined Planes.

In my last communication on this subject, I stated that the extra cost of constructing the locks in question was more than counterbalanced by advantages not yet enumerated. One of these is found in the circumstance, that the locomotive moves continually with the train throughout the whole route. Where inclined planes are employed, the danger and difficulty of passing the engine over them are so great, that the attempt is rarely, if ever, made. The consequence is, that at each plane the locomotive, which propels a train of cars, must be exchanged for another previously heated, so that a much greater number must be kept in immediate preparation for use than though this necessity for change did not exist.

But the principal advantage to which I alluded as overbalancing the extra expense of constructing the locks in question, is the diminution of the expense of grading, which would result from their adoption. The annual expenditure of a stationary engine being so very great, and that expenditure being nearly the same, however inconsiderable the height to be ascended, it becomes a matter of great moment that the whole elevation should be made at one point so as to require but one stationary engine. But Nature, in moulding the earth, evidently did not fashion its surface with a view to the most economical and convenient construction of inclined planes. The ascent from low to high grounds is frequently extended, either gradually or by successive partial elevations, through a distance of miles. Under these circumstances, by means of deep excavations and high embankments, the ascent is concentrated into a short space, and is then overcome at once by means of an inclined plane and stationary power. This occasions an immense cost, the greater part of which might have been avoided by the use of locks. In this case there would have been no necessity of making the whole ascent at once. It is wholly immaterial whether the locks necessary for this purpose are placed contiguous, or at the distance of miles from each other. We can, therefore, accommodate our work much more nearly to the natural surface of the ground, and thus each lock will probably save more than sufficient to defray the expense of its construction.

The recommendations of the locks in question, therefore, are: first, economy in the construction of the road by diminishing the expense of grading; secondly, economy in the operation of the road, by dispensing with stationary engines, by enabling the same locomotive to continue on

through the entire route, and also to move a greater load, since the facilities of rising perpendicularly are rendered so great that it will be practicable to lay the rails more nearly horizontal than at present. These advantages would all be felt, though no difference were made in the direction of the route in consequence of the adoption of this system, and would abundantly recommend its introduction. But these are not all. The dread of engineers for every slight elevation being overcome by dispensing with the necessity of inclined planes, it will be readily perceived that the route of a railroad may be made much more direct than at present, and thus not only the expense of constructing many miles of road, but the cost and time of transportation over it, be curtailed; and, finally, the danger to which life and property are exposed in passing over inclined planes will be almost entirely annihilated.

The only objection of any validity which I have heard urged against the locks in question is, that they have never been tried. That caution, which serves as a barrier to the introduction of visionary schemes and unsubstantial novelties, is a most useful quality; but in the present case we seek to introduce nothing new, but only the application of known powers and principles in a new method and for a new purpose. The properties of the screw and the powers of a steam engine are both well tested and understood. If, by means of the former, a few men are able to raise the largest ships, can any one doubt that the same power, properly applied, would raise a few railroad cars of one half the weight? And if human strength can effect this, will there be any scepticism as to the efficacy of a steam engine in producing the same result? There is no room for doubt; there is no possibility of a failure. But to make assurance doubly sure, let us enter into a brief mathematical estimate. The proprietor of the screw-dock in this city has informed me, that fifty men are sufficient to man all the screws at once, and that they will easily elevate a ship weighing two hundred tons a height of two feet in the space of thirty minutes. Now, the engines employed on the Liverpool and Manchester railway are of 30 horse power. What ours are in general, I know not, but let us suppose them to be of 20 horse power. One horse is generally reckoned equivalent to six men. Suppose we say five, and the power of our engine will then be equivalent to that of 100 men; but when our engine is said to be of 20 horse power, the velocity of that power is supposed to be 20 miles per hour—call it fifteen—the velocity of human power does not exceed 2 miles per hour. The effect of a given power is proportional to its velocity, so that the power of 100 men, provided it moves at the rate of 15 miles per hour, is the same as that of 750 men moving only two miles per hour. The effective power of our steam engine is, therefore, 15 times as great as that employed in raising ships on the screw-dock. But the weight we shall wish to elevate will never exceed 100 tons, or one half

the weight of a large ship. The proportion between our power and weight is, therefore, 30 times as great as in the case of the screw-dock. If, therefore, in the latter case, they can raise their weight 10 feet in 30 minutes, we shall be able to raise ours the same height in 1 minute, or 30 feet in 3 minutes. M.

[From the Richmond Compiler.]

**NEW MOVING POWER.**—The article below from Mr. James Herron, civil engineer, upon the subject of a new propelling power upon railroads, is one which deserves, and will unquestionably receive, the calm and dispassionate consideration, not only of scientific men, but of all who feel an interest in the advancement of science. The friends of Internal Improvement should give it their most patient attention. Its novelty may startle them, but what great suggestion in any age did not at first excite doubt of its feasibility? Witness the fate of Fulton and Oliver Evans. They were deemed insane and visionary in their day, but they are now ranked amongst the wisest men of our country, and the sigh of regret often escapes at the ingratitude and dullness of their countrymen.

Mr. Herron may expect to combat with incredulity, ignorance, and personal rivalry; but still he will find intelligent men disposed to consider with an impartial disposition the merits of his scheme. We pretend to but little science, but we confess we are struck with the feasibility of his plan. We think it deserves examination, and we are glad to find that an engineer, high in the estimation of the public, not only gives Mr. Herron's views a fair and liberal consideration, but seems disposed to concur in the principles upon which they are based.

In this era of improvement, every man who can make even the slightest addition to the cause of science, should be encouraged to the fullest exertion of his faculties for the public weal.

*Hydrodynamic Railway, or the Application of the Power of Rivers to the Rapid and Cheap Transportation of Produce and Merchandise.*

It has long been with me a matter of doubt, whether the water used in the lockage of canals was not in many cases an injudicious application of a valuable power, as in the case of a canal located along the valley of a great river having considerable fall in its bed, like that of the river James, which has 1222 feet fall from Covington to tide water, or about 4.74 feet per mile, rendering at least one lock necessary for every two miles in the average.

On investigating the subject, I find that the water power of the river is of itself equal to the transportation of a greater quantity of tonnage than can be passed through the largest canal, and this too with the astonishing rapidity peculiar to railroads.

I will therefore lay before you, in as succinct a manner as possible, this new though simple deduction of science.

The locks of the Chesapeake and Ohio Canal are 100 feet long, 15 wide, and, say we take one of the most approved lift, 8 feet, the "prism of lift" will then contain 12,000 cubic feet of water, which will weigh 750,000 pounds. Every time the lock is emptied, this quantity is transferred from a superior to an inferior level. If the valves are opened simultaneously, I am informed that the lock can be filled and

emptied in little more than two minutes; but say that it takes three. Now, this water is power, and if it were applied to a properly constructed "breast wheel," or where the fall of water is greater, to a "pitchback," we should have four-fifths of it available to set any machinery we think proper in motion. Let it be applied to an endless chain or rope, passing over suitable rollers along the line of a railway, after the manner of the stationary system of steam engines, we shall have a water power railway, entirely free from the objections that can fairly be urged to the stationary steam engines, of the necessity of keeping up the fire and steam, &c.

When the stations are two and a half miles apart, one twentieth of the power, according to Tredgold, will be expended in moving the chains; but I will allow a tenth of the power to effect this object on two mile stations, the chain being worked but for one mile.

We have then the four-fifths of 750,000 pounds, (the one-fifth being lost in the application to the water wheels) equal, 600,000 pounds, which, falling 8 feet in three minutes, is equal to 1818 pounds moved half a mile in the same time; which is at the rate of 10 miles an hour. Deducting from this the one-tenth, as that part lost in moving the chain, leaves 1637 pounds. And as 10 pounds are equal to the transportation of a ton, with the commonest railway wagons, it follows that the above power is equal to the transportation of 163.7 tons over half a mile of the road, while a boat would be passing through the lock of the canal; or it will transport 81.8 tons over a mile of the road in the same time, which is at the rate of twenty miles an hour!

But the maximum rate of transportation on canals is  $2\frac{1}{2}$  miles an hour, and as the mass moved is inversely to the velocity, we shall at this rate be able to transport 654 tons.

The water used would be at the rate of 66.6 feet per second. James river, even at Covington, in a dry season, yielded nearly three times this quantity, as appears from the Report\* of Mr. Crozet, who measured Jackson's river and Dunlop's creek in August and September, 1826. The mean of the results obtained by this engineer is 177.6 cubic feet per second, or 10,656 feet per minute; and we have this quantity with 7.81 feet fall per mile, the average down to Pattonsburg; before reaching which, however, the volume of water is more than doubled; and as we descend the river, although we have less fall per mile, we have at least six times the quantity of water to compensate for it; and the fall is still about  $3\frac{1}{2}$  feet per mile.

The heavier trade being descending, will add to the effect of this power; but disregarding this favorable circumstance, omitting the decimals in the fall per mile, and taking the minimum quantity, we have 10,656 cubic feet of water, equal in weight to 666,000 pounds, which, if permitted, will of course fall the 7 feet in a minute, and is therefore equal to 4,662,000 pounds falling one foot. Deducting one-fifth for loss in application, leaves 3,729,600 pounds. Now the load we can transport will depend on the velocity at which we would travel—say that it shall be 10 miles an hour, which is 880 feet per minute.

Dividing 3,729,600 by 880, the quotient is 4,238 pounds, moving with the velocity of 10 miles an hour!

From 4,238 deduct the one-tenth part, for

\* 5 Vol. Board of Public Works, page 108.

that lost on mile stations, in moving the chain, or rope; and dividing the remainder by 10 for the friction per ton of the carriages, and we have 381.5 tons transported at the rapid rate of 10 miles an hour!

And as each and every mile furnishes its own moving power, it follows that it is equivalent to keeping this quantity in motion on each mile throughout the line at the same time. And as the distance from Richmond to Covington is 257½ miles, this may amount to the enormous quantity of 98,236 tons; or to the transit and delivery of 3,815 tons hourly!

Having thus demonstrated the amplitude of this moving power, to an extent probably far beyond any demand we shall be able to make on it—which will be better understood by the general reader from the fact, that but 17 hours would be equal to the transportation of a greater quantity of tonnage than passed over the whole Baltimore and Ohio Railroad in a year, ending 30th September, 1833—it now remains to show that it can be employed at a reasonable expense.

The expense of erecting works for hydrodynamic transportation will depend on their scale, or magnitude, and on the greater or less permanent character of the materials used in their construction; also, on the extent to which we would employ the motive power. With regard to the latter, however, it should be observed, that we obtain it so cheaply, and in such excess, as to obviate, to a great extent, the necessity of expensive grading. This adaption of fixed power to an undulating surface, of any degree of slope, renders it peculiarly applicable to mountain localities, as by its means we can cross the bends of the river, thus shortening the distance, while a canal, or even an ordinary railroad for locomotives, should be conducted round them.

Another important advantage derived from the employment of this cheap power, is that we can substitute, for the iron rail, a broad granite tramway, similar to that extending from London to the West India Docks; which, although it will cost more per mile in the first instance, yet it will have great permanency to compensate for this. But the most important advantage to be derived from the granite tramway, is, that any man may bring his own farm-wagon, and, leaving his horses behind him, be drawn to market at a rate of 10 or 20 miles an hour, which would be in less time than would be spent in passing the locks of a canal: thus freeing the work entirely from the odious charge of monopoly brought against railroads.

To form an estimate of the cost, it will be necessary to suppose the works adapted to some definite amount of trade. Say that it shall be to the delivery of 100 tons per hour, or to the transportation of 50 tons at a time, at the rate of 10 miles an hour.

For this purpose I will suppose it necessary to erect a dam at every four miles; and that they may be built in the most substantial manner of stone masonry, I will estimate them at \$10,000 each; the average width of the river up to the Blue Ridge is 699 feet; above the Ridge, it will only be 275 feet. For water wheels of the best and most durable construction, say \$3000.

Thus we have 13,000, which, divided by 4 miles, gives \$3250 per mile, as the cost of the moving power.

#### Estimate of the expense.

Motive power, or proportional cost of	
dams per mile, - - -	\$3,250
Ropes, a double line per mile, -	1,800
Rope rollers, put up, - - -	850

*A broad granite, or marble tramway, double track, - - -	8,000
Grading and bridging per mile, say	2,000
	\$15,900
Add 10 per ct. for superintendence,	1,590
	\$17,490

High and unfavorable as the above estimate is, yet the whole cost of the moving power, including dams, water wheels, ropes, and rollers, will be much less per mile than such locks as those of the Chesapeake and Ohio Canal, which cost, as I am credibly informed, \$1500 the foot lift.

I have estimated for ropes, as they are in more general use than chains; and the above will be the cost of the newly invented rope, saturated with India rubber, expressly for this purpose; which is said to increase its strength as well as its durability.

When the stations or water wheels are placed 4 miles apart, each wheel would have to work 2 miles of the road at a time; but did the trade require it, double, or probably treble the foregoing tonnage could be delivered by erecting an additional water wheel at each station.

The following is the estimate of the amount of power to work the 4 mile stations, which those conversant with the subject will perceive to be very ample.

Friction and resistance of two miles of rope, - - -	600 lbs.
Ordinary friction of 50 tons of carriages and goods, 10 lbs. -	500 do.
Allowance for occasional gravity, at 20 lbs. per ton, - - -	1000 do.

Power allowed at the rate of ten miles an hour, - - - 2100

2100 pounds moved 880 feet in a minute, is equal to 1,848,000 pounds moved 1 foot; which is equal to 154,000 pounds falling 12 feet in the same time, which is, also, equal in weight to 2464 cubic feet of water. To which add one-fourth, for loss in application, and we have 3090 feet per minute, or rather more than 51 feet per second.

For the sake of conveying an idea of the probable cost on a large scale, I have supposed isolated dams to be used at regular distances, but the engineer will of course adapt his works to suit particular localities, sometimes preferring a continuous canal, substituting water-wheels in place of locks, and thus discharging the water, as it is used, into the next consecutive reach below. Or where great length of level occurs, the wheels may be made to discharge their water into the river, to be again taken out of the next dam.

On canals already constructed, where they have considerable lockage, and plenty of water, it is obvious that the trackage may be effected by the foregoing means; that is, by erecting a water-wheel along side of a lock, and extending a chain down the margin of the canal on the one side, which would be returned up the other.

And as they no longer need the tow-path, they may lay a light rail track, on which passenger cars may be drawn by the same power at any required velocity.

But in many cases, where they have not a superfluity of water, they had better substitute water wheels for their lock gates, widen their tow-path, and lay down a railway.

In conclusion, I invite investigation by

\* Wood and iron rail tracks, like those on the Petersburg Railroad, could be laid in a double track for 6000 dollars a mile. They would last much longer than when locomotives are used.

men of science, as it is certainly a subject of great importance to the country, now so extensively engaged in works of internal improvement.

JAS. HERRON,  
Civil Engineer.

Richmond, Va., May 26, 1835.

**AMERICAN PATENTS.**—For an improvement in *Axles and Boxes for Railroad Cars*; Dexter C. Force, and Frederick Davis, city of Baltimore, November 6. The axle is to be turned and made true in the usual way, and upon it is to be placed a metal ferule, or tube, fitting it exactly. The wear from running is to be between the ferule and the box contained in the hub of the wheel, so that no wear whatever shall take place on the axle itself. The material of which the ferule, or tube, is to be made, is not particularized, but it is said that it may be "either of composition, or of iron made case-hardened." There is no claim, but it is sufficiently plain that the patent is taken for the using of the ferule, or tube, between the axle and the box.

For *Thorough Braces for Carriages and Railroad Cars*; Frederick Davis, city of Baltimore, Maryland, November 6. These thorough braces are to be made of wood or of iron, although the latter appears to be preferred; it is to be of the kind called band iron. The brace is to extend along under the lower side timbers of the carriage, like those of leather, and is to have one or two hinge joints near its middle, where the body is to be attached to it. To strain, or take up the brace, there may be shackles at the ends, where it is attached to the jacks, furnished with a tightening screw and nut. Sometimes the brace is made double at each end, a piece, forming a strap, being attached to each jack; these pieces, and the ends of the braces, have rows of holes, through which bolts may pass, and by sliding these upon each other, the bolts may be passed through different holes, and the length of the brace be thereby regulated. "The improvements to which I lay claim as original, are the forming the entire brace of iron, other metal, or wood, in the peculiar manner I have described, so jointed and attached to the body as that it may be free to act on it without obstruction, when jolted or put in motion by the roughness of the road; and also the application of it to all descriptions of carriages or railroad cars, where thorough braces are required; also the application of the screw and the fixtures described to carriages where body loops are used, so as to raise and lower a body at pleasure, and to give a pleasant motion to the vehicle, without the use of the leather braces heretofore employed."

[From the Baltimore American.]

The Maryland State Loan of two millions, to bear an interest of six per cent. and to be irredeemable for thirty-five years, has been taken by Messrs. J. I. Cohen, Jr. and Brothers, of this city. The money is to be applied to the completion of the Chesapeake and Ohio Canal to Cumberland.

A Loan of a million of dollars, to bear the same interest and to run for the same period, is also required by the State for the completion of the Susquehanna Railroad to York. Offers will be received by the Treasurer at Annapolis until July 15.

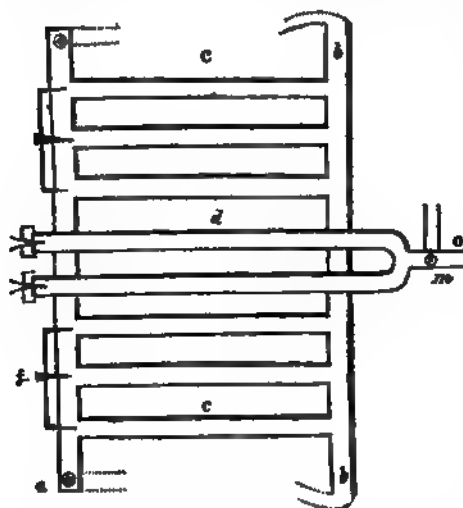

On the subject of the two millions Loan, we find the following paragraph in the Annapolis Republican of Saturday.

The Maryland State Loan, of two millions of dollars, for which we have had some of the large dealers in stock in competition, such as Messrs. Biddle, Chauncey, Moss, Cohens, &c. was finally taken yesterday by the Messrs. Cohens, of Baltimore, at a small advance upon the limit.—The terms will depend upon whether Bonds or Certificates be issued, which the Treasurer reserves the right to decide.

[From the London Mechanics' Magazine.]

*Improvement in the Fire Bars of Locomotive Engines.*

SIR,—The Rev. Dr. Lardner, in his evidence given before the Select Committee, says, "that he has witnessed a new set of grate bars melted in a single trip between Manchester and Liverpool." From this I conclude that the fire bars of locomotive engines are generally red hot; and supposing this conclusion to be correct, it strikes me that the red hot bars may be rendered of use to the engine—first, by increasing the energy of the fire, should the steam flag on the ascent of long hills, or in going over heavy roads; and, second, by producing a brilliant light, when locomotives undertake night journeys. Both these objects I propose to effect, by using hollow fire bars, and making them serve as so many small oil-gas retorts; or at other times permitting the air to pass through them to the furnace.

Suppose the front bar *a*, and back bar of the grate *b*, hollow, and of larger dimensions than the hollow fire bars *c c c*, all which open into them, except the two centre bars *d d*, which pass through both. In the front bar *a*, just opposite each fire bar, are entered jet points *f*, connected with a small forcing pump, with which the attendant may alternately inject oil into the bars on the right and left of the centre; which oil being converted into gas will pass into the bar *b*, from each end of which a pipe should pass upwards to the side or front of the furnace, as the form of the boiler may render most advisable. Previously to injecting the oil, the valves *e*, in the bar *a*, should be screwed down to prevent the air from entering. A pipe from each end of *a* should be carried down, and then to the forepart of the carriage, and end in a funnel.

To supply the gas for lighting the carriage, let the two centre bars, after passing through the back bar *b*, be united. There may be placed at *m* a three-way cock, to allow the passage of the air through the pipes by day, when the jet caps are unscrewed; and a communication may be opened by the pipe *o*, (which should pass through the cold water supply tank,) with the gas holder, during the night, the oil to be injected into the bars, *d d*, alternately by the engine.

I remain, sir, yours respectfully,

J. R. WHITE.

Wells, Somerset, Feb. 24, 1835.

P. S.—Has not Colonel Macerone given us a pretty good hint of the manner in which Dr. Church effects his condensation? There must certainly be some strong resemblance

between Mr. Hall's mode and Dr. Church's. Since speaking of one leads to mentioning the other, why not place Hall's fascine of condensing tube horizontally, and supply the place of water with an air draught or blast to the furnace, thus warming the air and condensing the steam? J. R. W.

RAILROAD.—We understand that the locomotive engine performed the journey yesterday from Boston to Lowell in one hour and seventeen minutes. The engine used on this occasion is an imported one, of large size, intended for the baggage train, and not for the passenger cars. There are some half dozen engines now building at the machine shop, (some nearly done,) which are intended to do the thing in less than one hour each way.

The completion of this magnificent improvement, (which, for solidity and permanence of construction, is not surpassed,) is a matter of universal congratulation. The future progress and prosperity of this town are placed as far out of the reach of all evil contingencies as any thing merely human can be. We can now fairly claim the advantageous distinction, that no inland town in the United States, (not a port of entry like Cincinnati or Albany,) is in possession of so many local advantages, or so many of the materials and means of expansive growth, and progressive advancement in business, wealth, and population, as the town of Lowell.—[Lowell Courier.]

QUOSQUA RANDEN?—To what lengths shall we go, where shall we stop—not in conspiracies, but in steamboat improvements? Heretofore the North River boats, which perform the distance of 150 miles, between this city and Albany, in from eleven to twelve hours, have been considered paragon. A new competitor however, the *Lexington*, is afloat which does some two hundred and ten miles in twelve hours! We take the annexed account of this boat, and her wonderful performance, from the Journal of Commerce.

The *Lexington* made her passage to Providence in twelve hours and twenty-eight minutes, after deducting eight minutes for stops, and her passage back from Providence to opposite the Dry Dock, in this city, was performed within twelve hours. For a part of the way her speed was twenty miles an hour. The distance from New York to Providence is called two hundred and ten miles. The construction of the *Lexington* is in several respects novel, and as she acquires her superiority from these novelties, they will be interesting to all persons engaged in the building of vessels. She is 208 feet long, has 23 feet beam, and 11 1-2 feet hold. She is timbered in a manner to give the greatest degree of strength, and is put together with the utmost accuracy and niceness of workmanship. But that which enables her to endure on so long a line, the immense pressure which bears upon the stem and stern while she is forced through the water at so rapid a rate, is that the deck is an arch, thus bringing the pressure against the ends of the timbers and planks, instead of against their sides. The stroke of the piston is 11 feet, the diameter of the water wheels 24 feet, and the revolutions 21 to 23 a minute. The boiler and the weight of machinery, as far as possible, is placed in the hold. Some of the passengers breakfasted in Boston yesterday morning. The *Lexington* was built by Bishop & Simonson under the direction of Capt Cornelius Vanderbilt, her owner. Her construction exhibits great knowledge of mechanical principles, and a peculiarly bold and independent genius. We ought to add, that notwithstanding her great speed, there are no wood-piles necessary on deck, and the expense of fuel is not more than half so great as in an ordinary boat. The speed with which she came down from Providence would carry her to New Orleans in four days.

SEABURY AND YOUNG'S IMPROVED PATENT  
BARK MILL.

We have received, from Messrs. Seabury and Young a drawing and concise description of their Bark Mill, to which we referred on the cover of the April number. They furnished us with drawings of the different parts, two only of which we have had engraved: one, a cross section, showing the interior of the mill; and the other the apparatus for cracking the bark as it passes in, to the

seen one of them induced to believe that rat rate machine, not so for which it is denominated a little finer, for id for breaking corn le, or preparatory to o meal.

addressed to Gibert & as some time since left in front of our office, and has attracted much attention, but we are unable to answer the numerous questions put relative to its cost, &c. and would suggest to the patentees the propriety of furnishing the necessary information.

Fig. 1.

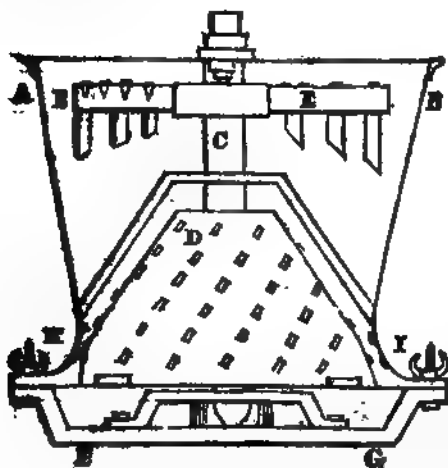

Fig. 2.

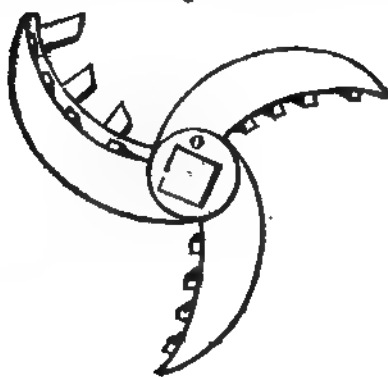

Fig. 1 represents a cross section of the mill when in position for use. A B, the pot; D, the nut or cone, with numerous projections on its surface, which revolves within the pot; C, the upright shaft by which the mill is put in motion; E E, revolving arms or breakers, with teeth pro-

jecting both upwards and downwards, which crack the bark as it passes into the mill; F G, the regulating beam, which is operated upon by the screws, H I, and raises or lowers the revolving cone, as the bark requires to be finer or coarser.

Fig. 2 represents the revolving arms as seen in Fig. 1, E E, attached to the upright shaft C, which passes through the mortice O. The object of these arms is to prepare the bark for the mill.

The following is one of the numerous favorable letters from one who has used the mill; and of Mr. Williams, we can speak as a competent and judicious judge of its merits.—[Ed. M. M.]

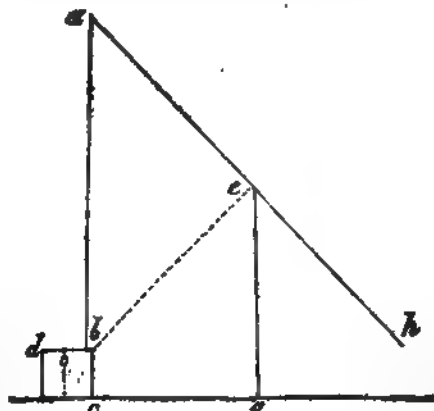

Messrs. Seabury & Young.

GENTLEMEN,—The bark mill I purchased of you I have had in operation about five weeks. I am highly pleased with it, and prefer it in my establishment to any one I have ever used. As an experiment, I have ground half a cord of bark in twenty-eight minutes, (forty-five revolutions,) and ground it well. I can cheerfully recommend it to the public, as a valuable improvement. Should you consider the above of any service to you to present to the public, you are at liberty to publish it. THOMAS WILLIAMS.

Vernon, Nov. 30.

To find the Length of the Sweep and Crutch for a Well—the Depth of the Well given.

Rule—The square root of half the square of the depth of the well, with the height of the curb added, is equal to the distance from back side of curb to centre of pin on which the sweep hangs; and the square root of half the space of that distance, with half the width of the curb added, is equal to the distance the crutch should be from the well, and the height of curb added gives the height of the crutch from the ground, consequently the length of the sweep will be twice the distance from the curb to centre of pin, less one foot. But to make it work easy, there should be an allowance of about six inches in height, and in the distance from the well, that is, the pin 6 inches lower, and 6 inches further from the well, which will give about one foot more on upper end of sweep, which allowance is in consequence of the upper end of the sweep being smaller.

Thus— $\sqrt{a b^2 \div 2} = b c$

$$\sqrt{b c^2 \div 2} + c b = g f$$

$$\sqrt{b c^2 \div 2} + f b = g c$$

$$\text{Then, } 2b c = a h.$$

Examples—I have a well 21 feet deep, and the curb around it 3 feet high, and 2 feet square—required to know the length of the sweep, height of crutch above the ground, and how far I must set the crutch from centre of the well.

$$21 + 3 = \sqrt{21^2 \div 2} = 17 \text{ feet, distance } b c \text{ from curb to pin.}$$

$$\sqrt{17^2 \div 2} + 1.5 = 13.528 \text{ feet, distance from well.}$$

$$\sqrt{17^2 \div 2} + 3 = 15.028 \text{ feet, height of the crutch.}$$

$$\text{And } 17 \times 2 - 1 = 33 \text{ feet, length of sweep.}$$

Then, as was stated above, we will make an allowance of six inches, or 0.5 of a foot,  $13.528 + .5 = 14.028 \text{ feet.}$

$$15.028 - .5 = 14.528 \text{ feet.}$$

S. A.

[From the London Mechanics' Magazine.]

Easy Method of Drilling Holes in Glass for Philosophical Instruments.

SIR,—Having discovered what I consider to be a new and also very superior method of cutting holes in plate glass for electrical and other machines, and also of cutting glasses for optical instruments, I am induced to send you a description of the same, in order that it may be beneficial to others. I will first describe the instrument necessary to be made for the purpose, and then state how it is to be used. Make of thick sheet tin a tube 3 or 4 inches long, the diameter of which, measuring from the outside edge, must be somewhat smaller than that of the hole required. Let this tube be converted into a drill, thus:

A is the tube; B the head of the drill, turned out of the wood, part whereof goes about an inch into the tube; C is a piece of iron wire for the pivot. The open end of the drill should have a few notches made in it with a file, so as to admit the emery, necessary to work with facility.

Determine the size of the hole you want, say half an inch in diameter; then cut such a hole in a piece of flat wood, being not less than 2 inches square, and half an inch thick. Next, mark on the plate glass the situation of the hole wanted; take some melted beeswax, with, or without rosin, and fix the piece of wood over the place previously marked; place the glass on something flat, whereon some baize or carpet has been first laid, to prevent the glass from sliding during the process; mix plenty of grain emery with water, and put it into the open part of the drill; now place the drill in the hole of the wood, and with a breast-plate and drill bow, about 2 feet long, commence drilling. You must work at first very slowly to avoid chipping the edge of the

glass, and afterwards proceed at a quicker rate, always taking care not to press on the drill more than sufficient to keep it steadily working, for otherwise there will be great danger of breaking the glass. When the drill is almost through the glass (which may be ascertained by looking at the other side of it), you must remove the carpet or baize, above alluded to, to obviate the danger of chipping the edge of the hole, and then proceed very slowly until the operation is quite finished. You will thus obtain a clean edged circular hole, with a corresponding piece of glass, and this without incurring the least risk of breaking. In this way a piece of plate glass, a quarter of an inch thick, may be cut through in less than ten minutes.

I have adopted this mode of cutting holes in plate glass for electrical machines, and it is obvious that it may be also applied to the cutting of glasses for optical instruments. Here, however, the diameter of the inside of the drill must, to allow for friction, be a trifle larger than the diameter of the glasses required; for if no allowance be made, it will be found that the piece of glass will be somewhat smaller than was required.

I am, &c. F. H.

Bath, Dec. 29, 1834.

AGRICULTURE, &c.

[From the Horticultural Register.]

ON THE CULTURE OF MILK-WEED, (*Asclepias Syriaca*).—Some four or five years since, in a conversation with George Manners, Esq. the British Consul for Massachusetts, on the various kinds of edible vegetables, cultivated in our gardens, he observed that, during a recent visit to Canada, he was informed that the young shoots of the milk-weed were used as a substitute for asparagus, and asked me if I had ever heard of their being cooked in the United States. I replied, that I perfectly recollected, when a boy, my mother often had them gathered from the fields and road-sides, with the dandelion, shepherd's sprouts, nettles, and other plants, which were collected as greens; but that I had never seen the plant thus used elsewhere, or heard it named as a culinary vegetable; but that I certainly would make an experiment in its cultivation, and as to its qualities, as an addition to our garden pot-herbs.

Having collected the seed in the autumn, it was sown early in the spring in drills, and covered an inch deep. They came up freely in four or five weeks, and when the plants were two years old, I took up a portion of the roots, and set them out about eight inches apart, in a trench six inches deep. The ground had been manured and thoroughly dug over, previously to forming the trench. The following spring, when the shoots were four or five inches high, they were cut, tied up in bunches, boiled and served up with melted butter, like asparagus; and they were as tender, and to my taste quite as delicious a vegetable, resembling in flavor the youngest and most delicate string beans.

As the plant is very hardy, exceedingly

prolific, easily cultivated, and such a valuable addition to our early vegetables, I consider a bed of it nearly as desirable as one of asparagus.

No better mode of cultivation can be adopted, than that for asparagus, as described by Mr. Chandler, in his interesting, instructive, and able article, which appeared in the third number of the Horticultural Register,—except the roots of the milk-weed should not be covered more than five or six inches deep.

Mr. Chandler is entitled to the gratitude of his fellow citizens for the valuable result of his experiments; and I freely declare that the mode he adopted and recommends, is the very best which I have ever seen published. I can confirm it, by having followed a similar process, but by no means so perfect in all its parts as that which he has so successfully tested. As a practical, intelligent, zealous, and enterprising tiller of the earth, he has no superior in this State; and the commendable gentlemen who have established a Farm School on Thompson's Island, could not have made a better selection in a superintendent of the art of cultivation in all its branches.

*Asclepias* (*Swallow-wort*), is a numerous genus of plants, there being forty-two species, which have been described by botanists, two of which only are found in Europe, but three in South America, while there are eighteen indigenous to the United States, and the others are divided between the West Indies and Africa. Many of the varieties are cultivated as ornamental plants in England and France, but the following kinds, natives of this country, are considered the most beautiful, besides being more hardy than those of more southern climes; still many of the latter are considered worthy of the green-house.

1. *Muschata*, so called by Bartram, for its strong and agreeable musk scent, is peculiar to the natural meadows of South Carolina, Georgia, and Florida. It is a low plant, of not more than five or six inches in height, with flowers of a pale green color, inclining to yellow.

2. *Venosa*, has leaves elegantly variegated with white and crimson veins, and the stems terminate in an umbel of pale flesh-colored flowers.

3. *Pulchra*, — Water-silk-weed, — has nearly erect stems, four or five feet high; umbels very small; flowers crimson purple. Grows on low, wet land, by the side of ponds.

4. *Variegata*, — Variegated. Leaves rough, umbels compact and come out from the side of the stalk; flowers of an herbaceous odor.

5. *Nivea*, — White, or Almond-leaved. Stalks two feet high, and of a dark green. Leaves deep green above, and pale beneath, smooth and rather stiff. Flowers green, with white nectaries.

6. *Incarnata*, — Flesh-colored, — has several upright stalks about two feet high, at the top of which are produced close umbels of purple flowers. Blooms in August.

7. *Decumbens*. — The stalks are declining, hairy, a foot and a half high; leaves narrow; umbels compact, at the extremity

of the branches; flowers a bright orange color.

8. *Verticillata*. Stalks slender, upright; umbels at the extremity of the stems; leaves in whorls of four, five, and six together; flowers small and of a greenish white color. Found in Roxbury and Dedham; blooms in July.

9. *Tuberosa*, — Butterfly-weed. Root large, fleshy, branching, and somewhat fusiform, but it is only by comparison with other species that it can be called tuberosous; stems numerous, growing in bunches from the root, hairy and dusky red; flowers numerous, erect, and of a beautiful bright orange color; grows in Woburn and Newton; blooms in August.

10. *Obtusifolia*, — Blunt-leaved. Stems erect, supporting a terminal umbel, at a distance from the leaves, which are opposite, ovate, heart shaped at the base; flowers large, of a greenish white, tinged with red; it is found in Cambridge and Mount Auburn; blooms in July.

11. *Phytoloccoides*, — Poke-leaved. A tall, large flowering species, of a delicate appearance; stem erect, four or five feet high; leaves large; umbels nodding, flowers large, petals green, nectaries white or flesh colored; grows in low grounds; blooms in June.

12. *Purpurescens*, — Dark-flowered. Stem erect; flowers of a dark crimson purple; grows in Cambridge and Newton, but is rare.

13. *Quadrifolia*, — Four-leaved. A delicate species, growing in dry woods; stems about a foot high; flowers flesh colored; is found in Roxbury and Brookline, and blooms in June.

14. *Viridifolia*, — Green flowered. An inelegant species, with small greenish umbels; is found in Leicester; blooms in July.

For the description of the third and sixth preceding species, I am indebted to Dr. Bigelow's excellent work, on the plants in the environs of Boston. There is a beautiful colored engraving of No. 9, and a more particular account of it, in his other most able and splendid publication, called Medical Botany.

15. *Amoena*, — Oval-leaved. Stalks from a foot and a half to three feet high; at each joint are two large leaves, which are blunt, thickish, stiff, smooth, with purple nerves; umbels rise from the top of the stalk and some of the upper axils; flowers of a bright purple color.

16. *Bubra*, — Red-flowered. Stem upright; umbels many, from the same common peduncle; a native of Virginia.

17. *Parviflora*, — Small-flowered. A native of South Carolina and Florida.

18. *Syriaca*, — Milk-weed, or Silk-weed. This species abounds all over our country, and for the many useful purposes to which it may be applied is deserving of especial attention. The root is perennial, and in April or May, throws out, like asparagus and hops, a great number of shoots; the stems rise to six or seven feet in height in a rich soil. When the leaves or stems are broken off, a milky substance, of a viscid consistence, exudes, from whence the plant derives one of its most general trivial names. The flowers appear in July, and

are in umbels of from twelve to sixteen on one stem, each containing thirty or forty single flowers, which adhere to the umbel by a long slender stalk, and has a sweetish odor. Each bunch of flowers is succeeded by three, four, and sometimes ten long, flat, and rough pods, which enclose numerous round, flat, thin, yellowish brown seeds, wrapped up in a beautiful shining white and soft kind of silk, which constitutes their wings, and by means of which they are conveyed with ease to a great distance by the wind; it has also given rise to the other trivial name, by which the plant is known in some parts of the country.

The great utility of the *Syriaca* or milk-weed in the arts has not been understood but since the middle of the last century, although it was introduced into Europe at a much earlier period.

A manufactory of articles from the silk was established in Paris in 1760, and it has long been employed at Lausanne, with advantage, as candle-wicks. Mr. Schneider of Liegnitz, has been distinguished for the zeal he has evinced in relation to the cultivation and preparation of this article, and has recommended it in two different pamphlets.

In the application of it to paper-making, Mr. Schmid, of Lunenburg, made a variety of very interesting and instructive experiments.

The cultivation of the plant has been found very easy. Mr. Schneider began in 1785, with but six plants, and in 1793 he had a plantation of 30,000, which yielded him 800 pounds of silk the first crop, 355 the second, and 600 the third. They were planted in rows about two feet apart, with a sufficient distance between the roots in each row. The silk was separated into two parts, the longer being used for spinning, and the shorter for hat making and beds.

Mr. Schmid, who was an ingenious manufacturer of paper, made several experiments with the capsules, or pods, which gave the following results:

1. From the interior white rind of the pods he obtained writing paper, pretty white, of good quality, and similar to the silk paper of the Chinese.

2. From the external green part of the pods, a greenish colored paper was made, which, when sized, was stronger than paper made from rags. It was almost as close in its texture as parchment, and even when unsized did not suffer the ink to pass through it. It was excellent wrapping paper.

3. From the bark of the stems he obtained a paper so like, in every thing, to paper made from rags, that the difference could scarcely be distinguished.

The silk when taken from the pods, and being freed from the seeds, is hung up in thin bags in the sun, and when perfectly dry, may be used without any further preparation, instead of feathers, horse hair, wool, or cotton, for cushions, bolsters, pillows, mattresses, and coverlets. From eight to nine pounds is sufficient for a bed, bolster, and two pillows. It is lighter and warmer, when used in forming coverlets or

comforters, than cotton or wool, and is nearly equal to eider-down.

For spinning, the staple of the silk is too short, when taken alone, and therefore is combined with flax, wool, cotton, or raw silk.

One third of this silk, with two thirds of cotton, forms a very excellent mixture for gloves, stockings, and other articles of like manufacture. One part of this silk, and two of rabbits' fur, forms hats exceedingly light, soft to the touch, glossy, and which have a great resemblance to beaver hats.

The plant throws around it long roots with new eyes; these can be cut off in autumn or early in the spring, before the milk flows, and may be divided into pieces from four to six inches long, which may be planted in trenches, four or five inches deep, in an oblique position, with the eyes or buds standing up.

Where the plant grows wild in abundance, a bed for culinary purposes could be easily formed, from the roots in the manner above described, and would be fit for use the second spring; by which two years would be gained over plants raised from the seed.

Besides the above named articles manufactured from the silk, I recollect having seen, at several of the annual exhibitions of the Massachusetts Agricultural Society, in Brighton, tippets, capes, bonnets, and various other articles, which were very beautiful. They were formed by sewing the tufts of silk by the part which is attached to the seed, to linen, cotton, or silk cloth in rows, one overlapping the other, like the shingles on a roof. They had the appearance of the most delicate and rich fur; and so simple was the work that a child could execute it.

For embellishing the outer borders of pleasure grounds, the skirts of roads, avenues, clumps of trees, the sides of groves, and to intermingle with shrubs, all the American varieties may be used with picturesque effect.

On examining some botanical works since writing the above, I found that Parkinson had received the *Syriaca* from this country, and cultivated it in his botanical garden of rare plants, as early as 1629. He called it Virginia Silk, and it was stated that the French Canadians were in the habit of eating the tender shoots as substitutes for asparagus.

It is but little trouble to form in every garden, side by side, beds of dandelions, sea-kale, milk-weed, and asparagus, which, from the last of March, until the green peas appear, will afford a daily and various supply of delicious vegetables. They are all perennial plants, and when once set out, and properly taken care of in autumn and spring, will yield abundant crops, for all time, without removal.

H. A. S. DEARBORN.

Roxbury, March 9, 1835.

[From the *Genesee Farmer*.]

**PROPAGATION OF FRUIT.**—There is not naturally a propensity in the human mind to take much pains in raising fruit, without some stimulating or exciting agency. The mind must be excited to some object

before it will produce any unusual effect. The subject before us, no doubt, has been frequently brought before the readers of the *Genesee Farmer*, and may have been presented in such a light as to render it useless for me to attempt any addition thereto. But, however, even if this be the case, there may be some who did not give the attention to it which its importance demands; and it may be well to stir up their minds by way of remembrance—not that I possess or profess any superior knowledge on this subject, but by frequently conversing on these things we retain them in our memory, and are prepared to impart such information relative to them as is required.

It is not a little singular indeed, after all that has been said and done, that there is such an astonishing apathy in relation to the cultivation of fruits, the luxuries of which add so much to the comforts and conveniences of life. However, by the aid of an exciting agency, such for instance as the *Farmer*, we see that people begin to take an interest in this subject, and the means are facilitated for acquiring practical knowledge relative to this and every other subject to which such a journal is devoted.

The propagation of fruit, as practised in different ways, has materially benefitted all those who are engaged in the useful occupation of raising it. Grafting and inoculation are the most successful methods now in operation for propagating fruit. And to these two then I shall confine myself, to make some remarks and observations for the consideration of all who are concerned.

**1st. Grafting.**—This may be successfully practised on apples, pears and plums, and I think to better advantage than by inoculation. The modes of performing this operation are different, but I have generally given preference to what is called cleft grafting. The mode of procedure is as follows: After the stock is chosen, select a smooth place and cut it off—even the top with a knife; this being done, make a slit near two inches deep down the middle of the stock, with a knife prepared for the purpose; then prepare the scion (taken from a vigorous shoot of the foregoing year, which should be cut in February,) sloping it on each side from a bud or eye, but leaving it thinner on that side which goes into the stock than on the outside, so that it may conform itself to the slit of the stock; then place the scion in the stock so that the inside bark of both may come exactly together. After this is done, the wounds of the stock are covered with an application of wax. The scions should be left with two or three eyes on them, and in case the stock be large, two of them may be inserted in one cleft, one on each side. Let not the scions be loose nor pinched, but a right temperature is necessary for their ready germination.

I have endeavored to render the method so plain, that it shall be the excuse of no one for not adopting it, for every one that has not good fruit may have it by a little exertion of their own. The only remaining difficulty is making the wax, and this can be done with but very little expense. Take 5 lbs. rosin, 2 lbs. beeswax, and 3 lbs. melted tallow, melt them together, and turn

it off into cold water, and work it till hard. This quantity of composition will be sufficient to set a number of thousand grafts. The means have been greatly facilitated for the making and application of this composition, from what they were when the old dirty method of using clay was practised. By a little attention, a person who has never practised it may perform the operation with complete success.

The best time for grafting is when the tree is about an inch through, taken off close to the ground. Although apples do well when put into the top of large trees, pears treated in this manner, my experience satisfies me, will never answer, because they will not unite firmly; hence their aggragation cannot be effected, and when loaded with fruit they are apt to blow off. Undoubtedly the most suitable tree for the pear is the thorn-apple. The aptitude of their fixidity to this, as far as my observation has extended, is not equalled by any other tree. However, if these cannot be procured, small apple trees will answer, if grafted close to the ground, and the earth raised around them. This may be performed in April or May.

**2d. Inoculation.**—This method of propagation, it seems, is better adapted to peaches, neotarinies, plums, &c., than grafting. I will give a description of a method as most successfully practised: "In August, take off a vigorous shoot from the tree to be propagated; then make choice of a stock about three or four years' growth, and in a smooth part of it make a down-right slit in the bark a little above an inch long, and another crosswise at the bottom of that, to give way to the opening of the bark; then with a penknife gently loosen the bark from the wood on both sides, beginning at the bottom; then prepare the bud by cutting it off, entering pretty deep into the wood, as much above as below the bud, to the length of the slit in the stock; after the bud is thus prepared, with the point of the knife and the thumb take out the woody part of it, carefully preserving the eye of the bud; then put the bud in between the bark and the wood of the stock at the cross slit, leading it upward by the stalk where the leaf grew till it exactly closes; then bind it about with coarse woolen yarn, the better to make all parts close regularly, and the bud incorporate with the stock, and the operation is done. The bud will be incorporated in about three weeks' time, when the yarn should be loosened, that it may not gall the bud. All buds should be taken from a vigorously growing shoot, and used immediately."

The choicest and the rarest varieties of fruit may be produced in a very short time by the above methods of treatment, and in fact I have known instances of grafts bearing the same year they were inserted—but they generally begin to bear in about three years. And who but he who has no taste for nature's richest productions would not even try the experiment? I have no doubt but all those who undertake the operation, will perform it with complete success, and ultimately be compensated for all extra expense and trouble.

We have a kind of apple, the value of which in the summer, (for they are not

good until then,) is from one dollar to one dollar and fifty cents, and we have kept them a year from the time they were gathered. They are called by the name of Rock Apple. They are pleasant flavored and annual bearers, and I think they might be profitably recommended to all orchardists. I mention this circumstance only to show the propriety and utility of propagation. As the season for grafting has approached, I hope the fruit growers of this country will avail themselves of this opportunity for having their plantations stored with the choicest varieties of fruit. R. S.

[From the Genesee Farmer.]

**BURYING BEES.**—Mr. Tucker: It is two years this spring since I first commenced bee-keeping. In the out-set I had no knowledge whatever of their management, and it was a stipulation of the bargain with the person of whom I obtained them, that he should, as occasion required, impart to me such facts as his experience would justify, in regard to their culture. This agreement was satisfactorily performed; and, aided by the information thus received, my success, for a tyro's, was such as to create an almost enthusiastic interest in this branch of rural industry.

In the autumn of 1833, I selected four hives, (double the number with which I commenced,) for wintering. Three of these had so limited a supply of honey, that I was advised to bury them, an operation which, in my mind, was little preferable to throwing them away. But I concluded to "try the experiment," and on one of the last days of November, they were "deposited beneath the little mound," where my mind figured them as possessing the interminable repose of "their last resting place." My absence on "the return of spring," that season when dying worms are wooed again to life, and the faded wing of the insect receives new colorings, beautifully wrought, from nature's dye, prevented me the pleasure of witnessing their exhumation, but the person who took them from their temporary sepulchre, (which was done about the 20th of March,) informed me that on their first introduction to the air and light, their animation was as perfect as that usually exhibited by bees in June. He said that he did not find half a gill of dead bees in all the hives. These hives gave swarms earlier and more frequently than the one that remained above ground, during the ensuing summer.

Last fall I concluded to continue "the experiment" with a single hive. The one selected was very light, probably not containing a sufficiency of honey to carry them half through the winter, had they been kept the usual way. In consequence of a rainy season through the last of November, they were not inhumed until December, probably as late as the 10th. They were occasionally fed in the fall, lest their supply should not be sufficient to insure a subterranean existence. My faith was as wavering when these last were buried, as on the previous winter, and as often as I looked at the spot where they were interred, I viewed it as the grave of my little insect friends.

They were taken up on the 28th of

March, and much to my satisfaction, found that the second experiment had terminated with the same happy results as the first. Not two dozen were lost, and *new comb was actually formed while they were in their "dark abode."*

My "modus operandi" is as follows. A hole is dug considerably larger than the hive, or hives, in every respect. On the bottom of the hole two sticks of three or four inches in diameter are placed for each hive, and on these the floor board, which should be a sound one, is placed. Another board, (two inch plank is preferable,) is put on the hive, and dry straw is as compactly as is convenient placed around it. This, in rainy weather, if the ground is clear from frost, allows the rain to pass freely down, while the space between the blocks furnish a ready reservoir, from which it is absorbed by the earth, without offering any injurious effects to the bees. The earth is placed upon the hive in a conical form, to turn the water from the hives, the top of which are about four inches below the surface. With respect to the experiment of 1833-4, I cannot say whether the apertures of the hives were closed, but in that of 1834-5, they were not. This experiment succeeded, but whether it is the best way of proceeding I shall not advise.

I regret that I did not weigh my hives, in both instances, previous to burying and on disinterring them, that the amount of food consumed might have been ascertained. But my experiments were both of them faithlessly tried, and unnecessary ceremonies were dispensed with. The quantity of honey consumed, however, was small, as none but very light hives were selected, and their weight in the spring was apparently nearly as great as in the fall. It is my intention in future experiments to mark items more particularly.

In selecting the spot for burying, a dry, and cold, rather than a warm one, should be chosen. An individual of my acquaintance buried on the south side of a dry hill, and an entire loss of all thus treated was the consequence. I attributed it, (though perhaps some other defect was the cause,) to such situations being more exposed to frequent freezings and thawings, subjecting the insects to more frequent change of temperature, a circumstance injurious to all that comes within its influence. If the situation is such as that the ground will freeze immediately after the trust is committed to it, and remain so until time to "remove the deposits," to me it would appear most favorable. Yours, etc.

WILLIAM BACON.

Richmond, (Ms.) April 23, 1835.

**STUMP LIFTER.**—Capt. L. NORCROSS, of Dixfield, Maine, has invented a new machine for lifting out or removing stumps. It consists of a large screw placed in a nut, which is attached to legs like those of a surveyor's compass. These, being sufficiently strong, are placed above the stump, and it is then grappled to the screw by chains or hooks. A large sweep, like that used in some old fashioned cider mills, having a nut to fit, is put upon the screw, and horses or oxen hitched on the other end, by means of which the stump is raised from the ground by driving round the sweep.

[From the Maine Farmer.]

CAN ONE HUNDRED AND FIFTY BUSHELS OF INDIAN CORN BE RAISED ON AN ACRE OF LAND?—Mr. Holmes: In a late communication in the Maine Farmer I stated my opinion that 150 bushels of Indian corn might be raised on an acre of land. This I am aware may be thought an unguarded assertion by some, perhaps most of the readers of the Farmer. This, however, was not carelessly or thoughtlessly made. It never has been my object to countenance wild and visionary schemes of fancied improvements; but to establish simple truth. Yet as this project is considerably greater than has been obtained by distinguished agriculturists, perhaps an exposition of my view may be proper.

One hundred and fifty bushels is 38,400 gills: of course, if we can raise this number of ears on an acre, that will make one gill each, it will be done. We all know that it does not require a very large ear to yield one gill of shelled corn. Mr. Bowles states that in rearing his crop the last year of 116 bushels to the acre, he planted 8000 hills with 4 plants to each hill; this, allowing one ear to each plant, would be 32,000 ears to the acre, and to have produced the quantity here mentioned would have been only one gill and one fifth to each plant, or four gills and four-fifths to each hill. That this cannot be obtained by extra manuring seems to be evident for this reason, that excessively high manuring produces such a luxuriant growth of stalks and leaves, that the sun and air are too much excluded to mature the ear. Here then is the principal difficulty, how then can this be obviated? I have frequently observed a perceptible difference in the proportion of the ear to the stalk in different kinds of corn under the same treatment, as regards manuring and cultivation. Cannot an improvement in the habits of the corn plants be made in this respect? Satisfactory experiments have determined that the same variety of corn, as well as other plants, may be brought to ripen earlier or later, by selecting for a number of years in succession seed that ripens earlier or later, as the case may be. But I have never been made acquainted with the fact that experiments have been tried in like manner for the purpose of obtaining a variety that should excel the superiority of the ears in proportion to the size of the stalks. Experiments on many kinds of vegetables have been tried, with remarkable success, to render the fruit more perfect in proportion to the vines or stalks. For instance, cabbages and melons and many others. A writer in the 2d vol. of the Maine Farmer page 115, says, "In reference to seeds, it has long been known to farmers and gardeners, that those that are new and fresh produce plants with more luxuriant foliage, and less inclined to run into flowers and fruit, than such as have been kept some time." "These circumstances," he says, "are carefully considered in the culture of cucumbers and melons, the seeds of which are seldom used until several years old. A similar attention to this law, in reference to the seeds of other vegetables, is productive of equal benefit. Peas, for example, are well known as apt to run to straw, where the ground is rich and moist. The employment of old seed is the only suitable remedy." A friend of mine once stated to me that his father, who was an experienced farmer, said that one bushel of old rye was worth two of new to sow. This was winter rye. I know not the reason of his preference, I mention it to excite the

curiosity of others to try experiments. H. C. says, (see page 131, of New-York Farmer) success in raising double ears or obtaining a seed that has this propensity, must depend, there is reason to believe, much more upon the selection of the seed for a succession of years from stalks bearing twin ears than upon the circumstance of its being the eight or twelve rowed kind. It may be remembered that H. C. was discussing the merits of these different varieties of corn. It recognizes however the existence of the principle we are now advancing, viz., the controlling effect of selecting seed from plants whose peculiarities we wish to continue.

If a propensity to produce twin ears may be obtained in this way, I know not why any other might not to some extent. I do not expect that all plants are alike susceptible of so great an alteration in their habits as some we have mentioned, but as the tendency to an excessive luxuriance of growth in the stalks of many kinds of plants seems at present to present an almost insurmountable obstacle to future improvement as to increasing their products to the acre, the subject is well worth a patient and persevering investigation.

There is another particular to which I would invite public attention, which is this. H. C. says, (also at p. 131, New-York Farmer, before referred to,) the richer the soil is made by manure, the later in all cases is the ripening of the corn, as the forage becomes more luxuriant and succulent. That this is a fact I admit as far as late ripening is concerned, but I do not admit the cause assigned. If I am correct in my observation, the most luxuriant corn shows its tassels and silk first and also fills the ear the soonest, though it does not ripen so soon. What is the cause of this? As far as my observation extends, the same remark will apply to grain. As I have given my views at some length on the effect of fermentation on the vegetation of grain, I will not enter into details on that point, but observe, that though Indian corn will bear the effect of excessive fermentation much better than grain, yet I am some suspicious that a re-rooting process may take place in corn, somewhat similar to grain, and this will certainly, if it does take place, protract the ripening of the stalk at the bottom, and of course the ear. Public attention does not appear to have ever been directed to this point. Another thing bears strongly on my reflection, though I am hardly willing to vouch for it, that I have at some time or other seen appearances on the roots of corn somewhat similar to those I have seen on grain. It is from a consideration of these facts that I have been led to advance the idea, that when we are properly skilled in the nature and use of manures, as well as have a correct understanding of what may be effected in the habits of plants, by attention to selecting seed in the best manner, as well as the best method of cultivation, that our crops of almost all kinds may be somewhat advanced.

Once more, and I have done with this subject for the present. I have never been in the practice of using Lime and Gypsum and other manures of a similar nature myself. I shall make a beginning this year. That these manures have "wonder working powers" I have no doubt, and when used with skill will be of essential benefit in producing the effect desired. But we must not expect complete success all at once; nor will it do to establish theories on solitary facts, we must have decisive evidence of a plenary kind.

J. H. J.

Peru, April, 1835.

[From the New-England Farmer.]

WASH FOR FRUIT TREES.—A friend and patron of our paper wishes us to inform him what is the most improved wash for fruit trees, and says, "If I remember right there has been an improvement on Forsyth's composition." The following was, some years since, recommended by Mr. Benjamin Wheeler, of Framingham, Mass.

"Dissolve two pounds of potash of the first quality in 7 quarts of water, for the bodies of the trees. If the limbs are covered with moss or lice, I take a painter's brush and apply the solution to the moss, &c. with care not to touch the leaves or buds. It may be done at any time of the year when we are most at leisure. Once in two to four years is generally sufficient. I have no general rule, however, but wash them as often as they appear to need it, which is always when the bark is not smooth.

"No person need be afraid," Mr. W. continues, "of this application's injuring fruit trees; but it may be applied with the utmost confidence. I have used it for nearly twenty years with great effect. The reason it has not been more generally used is that it has been fashionable to daub the trees with lime, clay, manure, and other compositions, which take two or three years to wash off before the tree will look natural. When this solution of potash is applied it has the desired effect immediately. It kills the moss and lice at once, and the first rain that comes washes the bark perfectly smooth, and gives it a fair, natural, and healthy color."

ORIGIN OF "HERBEMONT'S MADEIRA GRAPE."—\* \* Since I wrote to answer your inquiry, I have learned a little more concerning the origin of the vine called "Herbemont's Madeira." It certainly has been received from France, under different names, and also from Madeira. It is most undoubtedly one of the most esteemed families of vines in Europe. In certain situations in this country, Charleston for example, it does most admirably well. It has been received from France by the names of "Muscat gris," "Pineau," and "Maurillon." I have not yet been able to learn by what name it has been received from Madeira. It changes some of its characters so much in this country, as scarcely to be known again—for here it grows to the size and vigor of our strongest native vines. The nomenclature of the vines is, in Europe, in such a chaotic state, that it would take the labors of at least twenty Hercules to clear it up. Now that this culture is fairly begun in this country, we should be very particular with our names; and confusion in nomenclature is frequently inextricable, at the same time that it is exceedingly disadvantageous to the cultivators. The names should be short, if possible, and unchanged after they have been adopted. I would suggest, for example, that the excellent kinds introduced by the names of "Norton's Virginia Seedling," and "Cunningham's Prince Edward," be simplified, by suppressing every thing but the names of the gentlemen entitled to the honor of naming them.—N. HERBEMONT.

[Farmers' Register.]

NEW-YORK AMERICAN.

JUNE 6-15, 1835.

FOREIGN INTELLIGENCE.

From Paris, we have our papers to the 24th April, by the Albany.

The *Journal du Havre* of Thursday, 23d April, has the following:—"Commodore Elliott, of the American frigate the Constitution, arrived here this morning from Paris. It is believed that the Constitution will sail this evening."

The Constitution was at Cherbourg on the 28th, to take in water.

The Paris dates are of the 28th of April. The *Courrier Francais*, and other opposition papers, pretend to quote Mr. Livingston as saying, in relation to the amendment requiring explanations previous to the payment of the indemnity, that his return to Washington would be the signal of hostilities. This is manifestly a fabrication. Mr. Livingston would not be guilty of the imputation of saying such a thing, even if he thought it; and he is too sagacious a man, and understands the affairs of both countries too well, to entertain any such opinion.

This is a question which will not be decided by silly talk, or shallow blustering, or idle rhodomontades on either side—but by the calm good sense, and reason of the thing, and by the mutual interest of each of the parties, to preserve a good understanding with the other.

It must not be disguised however, from our readers, that Mr. Livingston, as we have from private but authentic sources, the certain assurance—consider the proviso in question, so nearly tantamount to a rejection of the indemnity, that he feels himself bound by the spirit of his instructions, to return in the Constitution to the United States—which frigate therefore may be hourly looked for.

On the other hand, the French Ministers are desirous to avert all difficulty, as the following extract from a letter, written by a gentleman who is not at all likely to be mistaken, will show.

Extract of a letter from Paris, dated April 28d, 1835.

"The departure of Mr. Livingston for America will doubtless occasion much speculation. I can give you the positive assurance, however, as received from M. de Broglie through my friend M. Jay and others, that Ministers attach not the slightest importance to the amendment of which you will hear so much. They are (said M. de Broglie) perfectly satisfied with the explanations already given by Mr. Livingston, and they propose submitting an amical note at Washington, inviting the U. S. Government to confirm these explanations.

It is simply to comply with the decision of the Chamber as imposed on them, and for the purpose of protecting them before the Chamber. Mr. Livingston however, takes a very different view of the case.

The famous process going on in the Chamber of Peers, against a mass of 800 or 900 persons, taken up in the Lyon's affair has placed, the government in a very awkward situation; it was one of the greatest errors of Louis Philippe, and how it is to be got over, is difficult to say.

This market continues to be good, for cotton.—The American planters must make much money this year, and the merchants who had nerve to do business notwithstanding the high prices, will make money also."

Parliament having been prorogued till the 12th of May, in order to give time for the new elections rendered necessary by the late ministerial appointments, there is nothing of much interest from England. Many of the new official persons had been re-elected; among them Mr. Labouchere, the Master of the Mint, whose opponent was young D'Israeli, the author of *Vivian Grey*; and Mr. Fox-Leith Thompson, for Manchester. The great strug-

gle, however, was to be against Lord John Russell, for South Devonshire; and very strenuous efforts were making by the Conservatives to defeat him there, if possible.

The following members of the administration have already been returned without opposition:—Right Hon. T. B. Ruse, for Cambridge; Sir T. Troubridge, for Sandwich; Sir J. C. Hobhouse, for Nottingham; Lord Seymour, for Totness; Mr. W. H. Ord, for Newport. An opposition is threatened to Lord J. Russell, in Devonshire; to Lord Mertham in Yorkshire; to Mr. Labouchere, at Taunton; and to the Lord Advocate, at Leith; but we have very little doubt that in all these cases it will be unsuccessful. The only places where a contest has actually taken place are Manchester, where it will be seen that the President of the Board of trade has defeated the Tory candidate by an overwhelming majority of not less than 1300, and Taunton, where Mr. Labouchere has been returned by a majority of 170 over Mr. D'Irland.

With the Ministerial candidates, at the last general election, rejection was the rule, not the exception; at the elections consequent on the breaking up of the late and last Tory Administration, we have well grounded hopes of being able next week to announce that the members of a liberal Ministry have been returned to Parliament, without a single exception. So much for Conservative prognostications.

The affairs of Spain seem pretty much as usual, though the new commandant for the Quana, Valdez, has declared, it is said, he would not see Madrid again till he had put an end to the insurrection. A rumor that France had been called on by the Cabinet at Madrid to interfere more effectively, for the suppression of the civil war, is discredited by the London papers—which justly argue, that even civil war is to be preferred, to the perils of intervention of a foreign army.

THE RESTORATION OF THE JESUITS.—We copy the following from the *Standard*:

"Rome, Jan. 23, 1835.—At a solemn sitting of our Holiness the Pope at Rome, it was decreed—

"His Holiness the Pope Gregory XVI, in consequence of a report which was, the Secretary of the 'Holy Congregation for the Propagation of the Faith' (i. e. the Jesuits) have made to him, has given and accorded to us in the name of our Lord and Saviour, as his representative, &c., as follows:

"1. Plenary indulgence, applicable by means of the prayers of the church for the souls in purgatory, as well as applicable to all and to each of the faithful, of both sexes, who, truly penitent, and having confessed and received the sacrament, shall visit devoutly the church of Montmartre, in the diocese of Paris, (under the Restoration it was Mount Valerian,) as well as the great cross of Calvary, which is erected in the same church, and shall so visit the church and cross aforesaid on the days of the festes of the invention, and of the exaltation of the holy cross, and shall pray devoutly there for the propagation of the faith. (The cross here spoken of was a cross planted by the Jesuits under the Restoration.)

"2. A partial indulgence of 100 days to be gained twice in the month, by those who shall visit devoutly the great cross, or Calvary, in the church aforesaid, on the days designated by the ordinary.

"Given at Rome, &c. HYACINTHUS."

(i. e. M. de Quelen, Archbishop of Paris.)

TUNIS.

The following is the address of his Excellency Mohammed Noun-Effendi, Envoy Extraordinary and Minister Plenipotentiary of the Sublime Porte, to His Most Gracious Majesty, at a public audience granted yesterday:—

"Selected for this mission through the confidence reposed in me by my august master, the Sultan, to be his representative to your Majesty, I deeply appreciate the honor conferred in an audience which furnishes me with the opportunity for expressing to your Majesty the particular sentiments of His Imperial Highness.

"The perfect harmony that has existed so many years between the Sublime Porte and Great Britain is not solely founded upon esteem and personal considerations; it exists upon political interests, which can only serve to strengthen the friendship already subsisting between the two august Courts.

"The commerce of Great Britain has experienced

in the Ottoman Empire perfect freedom and facilities, such as have not been met with in any other country, and the people of his Highness have enjoyed without restriction the admirable productions of industry created by your Majesty's subjects.

"In consequence, the Sublime Porte, duly appreciating and esteeming the importance of our friendly relations with one of the most enlightened and most powerful nations among the powers of the earth, does not doubt but that a system both benevolent and reciprocal will gain the entire solicitude of your Majesty's Government, and that it will shortly be considered as a means only for strengthening more and more the bonds of friendship which unite the two Powers.

"This union, Sir, is one of the objects most precious and nearest to the heart of his Highness, my august master, and it is a proof of the sincere and affectionate sentiments professed by him for your Majesty's royal person.

"April 29, 1835."

THE EARTHQUAKE IN CHILI.—By an arrival at Baltimore, we have been put in possession of Valparaiso papers to the 18th of March. They contain the particulars of the terrible earthquake on the 20th of February, the ravages of which were even more extensive and deplorable from the verbal accounts almost the whole of the South public has been swept, as a structure. Even at the island more than 300 miles from the was felt with tremendous the anchoring ground retire that where there had been 1 the ground was laid bare: 5 returned with such fury, 1 mofiated the town. The government and garrison saved themselves by fleeing to the heights; but beyond this, the particulars had not been received.—We subjoin such translations as our time permits, and shall perhaps give others in a future number.

VALPARAISO, March 4.—Every day we receive new details of the sad calamity which has fallen the greater part of the cities and towns in the Southern section of the Republic. The ruin of Concepcion and Talcahuana is complete. At Concepcion there remains only one house for the shelter of the inhabitants. Of Talcahuana, according to the more recent advices, not a vestige remains. After the earthquake, the sea retired from the coast where the town was situated, about a mile, and then rolled in over the whole town, and in its reflux swept it almost entirely away.—The fragments that remained were demolished and buried by two subsequent seas which successively overwhelmed the site of the town. When the sea had regained its usual level, the inhabitants, all of whom at the approach of the inundation fled to the neighboring heights, returned to the place where the town had been situated, and for several days many of them have been engaged in disintering some remnants of their property. The sea rose 33 feet above its ordinary level, and drove into the town-square the national bark *Mapocha*, and placed other vessels in imminent danger.

The road from Talcahuana to Concepcion is almost entirely destroyed by the deep fissures and sloughs which have been created, consequently the destruction of property and the interruption of the channels of intercourse which facilitate the subsistence of a town, must be alarming.

TALCA, Feb 20.—Two hours ago this town ceased to exist. This may truly be said, for its regular and comely edifices, which gave it the third place among the cities of Chili, are transformed into a mass of ruins, or buildings so essentially damaged that they cannot be inhabited without great danger.

TALCA is 120 miles N. E. of Concepcion. At San Juan de Dios, where some bricklayers were at work when the earthquake came on, they almost all perished. Children and grown persons have alike disappeared from the number of the living, and in short, the whole presents a scene of deplorable calamity.

The movement of the earthquake was not so violent as it was long-continued. It commenced here at about 8 minutes past 11, and it is calculated that the two principal shocks lasted 3 minutes and 20 seconds.

VALPARAISO, March 3.—By letters and passengers brought by vessels which arrived here day before yesterday, yesterday, and to-day, the news is confirmed of the ravages of the earth-

quake in the provinces of Concepcion and Maule.

Concepcion, Talcahuana, Penco, Tome, Arauco, Colcura, Pemuco, Yumbel, Rere, Los Angeles, La Florida, Coelemu, Ranquil, Cauquenes, San Carlos, Quirigua, and other towns of both Provinces, have been ruined in consequence of that terrible event. Talcahuana, Penco and Tome were thrice inundated by the sea, and in Arauco and Colcura it rose to the walls. In the port of Concepcion also, it rushed back and forth several times.

The loss of lives in Concepcion does not exceed 50 odd; in Talcahuana, very few.

If we except the national schooners Juana and Jertrudis, which were stranded in the port of Concepcion, no other vessels have suffered irreparable injury.

The earthquake is said to have been occasioned by the eruption of the volcano of Antuco, in the latitude of Concepcion, and about 30 leagues from the coast.

For the sufferers \$8000 had been subscribed in Valparaiso prior to the 16th March, \$1000 in the Almendral, \$6196 at Santiago, two Convents \$3300.

[From the Journal of Commerce.]

A WEEK LATER FROM BUENOS AYRES.—By the brig Paulina, Captain Clark, we have received Buenos Ayres papers to April 4th.

The balloting which was going on at the date of our previous advices, had resulted in the ratification of the resolution of the House of Representatives appointing Gen. Rosas to the chief authority of the Province,—by a vote of 9316 to 4. Gen. Rosas is therefore Governor of Buenos Ayres, with extraordinary powers.

A treaty of peace and alliance has been celebrated between the Governments of the Provinces of Tucuman, Santiago del Estero, and Salta.

An engagement took place on the 7th of March, between a body of Buenos Ayrean troops and Indians on the one part, and a body of hostile Indians under Lanquitriz, on the other. The latter were totally defeated, with the loss of killed, 133 Indians, and 67 Squaws—prisoners, the Caciques Guichel, Lamen and his son Antil, and 353 Squaws, besides 34 Christian captives, of both sexes, recaptured—and there also fell into the hands of the victors, 2000 sheep, 300 goats, 200 oxen, and 132 horses.

As if the Republic of La Plata were not sufficiently broken to pieces, a section of Salta called Jugui, has seceded therefrom, and declared itself independent. It adds one more to the allied Provinces constituting what is sometimes called the Republic of La Plata.

#### SUMMARY.

THE REPUBLIC OF LETTERS.—Under this title Mr. Geo. Dearborn, of this city has published in weekly numbers, at 6 1-4 cents each, during the past year, a periodical, embodying a choice selection of approved literary works.

The 52 numbers published, constitute two handsome volumes, embracing, as by reference to the advertisement, will be seen, some of the standards of English literature.

In order to inspire additional confidence in the selections for this publication, and in the discrimination and taste, which will be exercised in that matter, the publisher has made an arrangement with Mrs. A. H. NICHOLAS of this city, to superintend this department. Competent as she herself is, to such a task, she will yet be further aided by the suggestions of her brother C. F. Hoffman—and by those of Washington Irving, G. C. Verplanck and E. Everett.

Under such auspices, we cannot go wrong, in claiming for the Republic of Letters—large and general patronage.

A night boat is now running on the ferry between this city and Powles Hook. After the 15th, the Newark Railroad Company will also run a night car. All such arrangements contribute to mutual benefit and convenience.

ACCOUNTABILITY OF STEAMBOAT CAPTAINS, STAGE OWNERS, &c.—We have been instant in season and out of season, to arouse public attention

to the necessity of subjecting to the penalty, which the laws will not fail to inflict upon carelessness, ignorance, or recklessness, all through whose instrumentality, accidents in steamboats, or other public conveyances, occur.

In furtherthence of this purpose, we annex, from a London paper, the report of a case in Scotland, as affording an instance in point of the value of such investigation; whereby, if there be criminality, it is ascertained and punished—and if not, the fact is made manifest, and the party against whom rumor and suspicion might otherwise be operating disadvantageously, is sent forth free and unimpeached. Hence it is clearly for the interest of all, but guilt, that such investigation should be had:

#### CIRCUIT COURT, GLASGOW, April 22.

Robert Wallace, master of the Kilmun steam vessel, was accused of culpable homicide. The charge was to the effect that he had contravened the 44th and 46th sections of the regulations of the river Clyde trustees, formed under act of Parliament, in having navigated his vessel at a greater distance from the quay at Dunglass than was necessary for the reception of passengers from a small boat coming off from that quay—in having thrown a rope to the small boat for the purpose of attaching it to the steam vessel, at a time when, from the state of wind and tide in the river, it was improper and unsafe to do so, and dangerous to the lives of the persons on board—and also with setting the paddles of the steam vessel in motion while the said small boat was attached to her, or at least before the boat was removed beyond the influence of the steam vessel—by all, or part of which neglects and contravention of the regulations, the small boat was run down, and at least nine individuals were culpably, recklessly, and negligently drowned, and bereaved of life by the pannel, Robt. Wallace. Mr. Wallace pleaded Not Guilty to the charge.

Several witnesses were examined for the prosecution, two of them bricklayers, who had been on board the small boat, and two of them passengers in the Kilmun; but from none of the evidence could there be adduced the slightest imputation upon the character or conduct of Captain Wallace upon the melancholy occasion referred to. It was proved that the weather was stormy—that the small boat was over crowded—that Captain Wallace called distinctly to the ferryman to let go the rope, when he found the streamer to be in a perilous position—that he did not direct the engine to be put in motion till he had so called at least twice—and that had the hold of the rope from the small boat been withdrawn when the orders were given, the accident would not have happened.

After proceeding with part of the evidence the Advocate Depute stated to the Jury, that he had thought it his duty to bring the case before them for the purpose of satisfying the ends of justice—and in deference to that anxiety so universally felt that every case involving, as this did, a great loss of life, ought to receive every possible investigation—also, that the public might have an opportunity of seeing whether any blame was attachable to the pannel, or any other person, in the melancholy event which had occurred; and likewise by instituting a trial here, to induce others to act in similar circumstances with the greatest caution. Having, therefore, brought forward the case, he was satisfied that he had done enough to show the Jury and the public that no blame whatever could be attached to any party, and now considered himself perfectly justified in proceeding no further with the case.

Mr. MAITLAND (Counsel for Mr. Wallace) said he had been instructed by that gentleman to thank the Public Prosecutor for having brought the case before the public, and also for having in so very handsome a way withdrawn it. That respectable gentleman, he observed, would never cease deeply to regret the loss of life that had occurred in circumstances with which he was so intimately connected, however guiltless he might be of the causes which led to that catastrophe.

The Jury having returned a verdict of Not Guilty, the Court dismissed Mr. Wallace from the bar, after stating that he left it with a character not only unimpeached, but, on the contrary, with the credit of having always conducted himself with great propriety.

EDWARD JOHNS has been recognized by the President as Russian Consul at New Orleans.

SPIRIT OF ENTERPRIZE.—We understand it has been determined upon by the inhabitants of the thriving town of Flushing, to immediately open a correspondence, by Committee, with the various Manufacturing interests of Newark, Patterson, Lynn, and other towns in different parts of the Union, calling their attention to the superior advantages which Flushing presents, and offering land, &c. to them at a low perpetual rent, with the privilege of purchase, as an inducement for them at once to locate themselves in that town.—[Communicated.]

LICENCES IN BROOKLYN.—We learn from the Brooklyn Advertiser, that the Common Council of that city have resolved,—

1. That no retail license be granted to a Grocer.
2. That licenses be granted to citizens only.
3. That Tavern licenses be granted strictly in conformity with the Act in such case made and provided.

This is bravely done in our sister city; and may operate, possibly, advantageously upon our own Common Council.

PUBLIC SCHOOL SOCIETY.—From the 13th Annual Report of the Trustees of the Public School Society of this city, it appears that the number of schools under its charge, including 23 primary schools, is 55, comprising an aggregate of 13,897 pupils, 7354 of whom are males, and 6543 females. Increase during the year, 1390. Of the whole number, 1242 are colored, viz. 611 males, and 631 females. The expenditures of the Society, for all purposes, including buildings and the payment of \$10,000 to the Savings Bank, have been, during the year ending May 1st, \$115,518 95. The receipts have amounted to an equal sum, including a balance of \$8400 21 on hand at the commencement of the year, and \$15,000 borrowed. Balance in the Treasury 1st of May, \$1336 09. Of the receipts, \$78,462 45 comes from the School Commissioners. The whole debt of the Society at the present time is \$45,000. The value of their real estate is probably three or four times that sum.—[Journal of Commerce.]

WILD, WILDER, WILDEST.—The spirit of speculation in this country, is now going rapidly through these degrees of comparison. We have seen some of the positive, and even of the comparative degree in this city; but the superlative was left for Charleston, where, as we learn from the Courier of the 3d inst., the subscription to the new "Bank of Charleston," of which the capital is only two millions, exceeded, in the city of Charleston alone, eighty-one millions of dollars; and as books were opened in other parts of the State, that amount was swelled probably to ninety millions of dollars.

As one fourth was required to be paid down at the time of subscription, the sum paid into the hands of the commissioners in Charleston, was twenty millions, two hundred and seventy-seven dollars!—more than ten times the whole capital.

The task of distributing this stock is one, that no one need envy to the commissioners.

There is a common saying, "It will be all the same an hundred years hence"—and a deal of true philosophy is there in the proverb. How insignificant appear all the quarrels, and clashing interests, and opposing plans and strokes of outwitting policy, and shrewd diplomacy, which agitate us now, when we consider that "a hundred years hence" the result, whatever it may be, of all this turmoil will not then be felt by those who will then be upon the stage! The descendants of Charles I. of England, and Oliver Cromwell intermarried in the fourth degree.—[Alexandria Phoenix.]

PASSAGE IN SHAKESPEARE CORRECTED—"Vaulting ambition that o'erleaps itself," should be "its self." Sell is saddle an Spenser and elsewhere, from the Latin and Italian. This emendation was shown to the late Mr. Hazlitt, an acute man at least, who expressed his conviction that it was the right reading, and added somewhat more in approbation of it.—[Landon's Examination of William Shakspeare.]

**FLUSHING PROPERTY.**—About one hundred lots in the village of Flushing were sold by Messrs. Franklin & Jenkins yesterday. The whole sale was gone through with at prices deemed unusually high. Most of the lots were 25 to 100 feet, and brought from 250 to 600 Dollars each; others measuring 50 to 100 feet sold, the highest, at 1500 Dollars.

Yesterday, a son of Jacob Van Clief, six years old, fell into a well at Staten Island, through the door of the casing—the well was forty feet deep, with 12 feet of water in it. A rope was thrown to him which he made fast to his body, and was hauled up uninjured.

It would seem that the traffic in wives is not confined to England; but, though in other countries they may not be more beloved, they appear to be more dear. The *Gazette du Limousin* states that, a few days ago, two artisans of Compreignac, near Bellac, struck a bargain over their cups, by which one transferred his wife to the other for 1,000 fr. The repudiated spouse, however, who is young and handsome, refused to give herself up to the purchaser, who has threatened to bring an action against the husband upon the contract, which is duly signed and sealed.

**IMPORTANT TO MARINERS.**—Several successful experiments have been tried on the North Humber Bank, with a portable apparatus admirably adapted for conveying a line from a distressed ship or wreck, to the shore.

The apparatus consists of a gun (manufactured by Mr. Blanch, gun maker, of Hull), which will propel a line made fast to an arrow to the distance of 150 to 200 yards, and thus obtain from even a single individual on the beach, all the assistance which such exigencies require.—[Army and Navy Chronicle.]

A traveller in the Island of Cuba has estimated that ten thousand dollars worth of cigars are consumed daily in the city of Havana.

The Navy Commissioners have issued proposals for the delivery of white oak keelpieces and other timber for eight seventy fours, eight frigates, and ten sloops of war, by the first of August, 1836, at the naval stations of Portsmouth, Boston, New York, Philadelphia, and Norfolk. This is an addition of nearly one third to our present naval force. We observe in the list of the European navies, that several States have a large proportion of steam vessels, and particularly the English and French. Would not steam ships be greatly the most efficient force for the defence of our coast with its large bays and rivers?

The Boston Commercial Gazette, making a comparison of our naval resources with those of other nations, estimates that we have at present in the merchant service about 70,000 seamen.—[Balt. Am.]

A tremendous storm of both wind and hail occurred a few days since in Robertson and Sumner counties, (Ten.) Some of the hail stones are said to have been weighed and to have been of the incredible size of *three quarters of a pound weight*!—There was a great destruction of timber and much damage done to the plantations but no lives lost so far as we have heard.—[Nashville paper.]

**CHOLERA.**—This disease seems slowly ascending the western waters, and settling at various points along the Mississippi valley. The Pittsburgh Statesman, of the 27th ult., says the steamboats arriving at Louisville have had many cases on board; but it makes no mention of the disease having taken root on shore, yet, at that point.

**A PARENT'S LOVE AGAIN PAINFULLY EXEMPLIFIED.**—On Friday last, the sloop John Felter, owned and sailed by Capt. Lemuel June of this place, put in at Pullen's Point for freight. Mrs. June, and her little son about four years of age, were on board, having just returned from New York. The captain and his hands had come down to the village, leaving Mrs. J. and the child on board, when the latter accidentally fell overboard. The tide was running strong at the time, and the mother, regardless of her own life in her anxiety to save her child, plunged in after him. Their cries were heard by a man some distance from the Point, who hastened to the spot barely in time to snatch the mother from a watery grave. He then discovered the

child some rods from the vessel, drifting with the tide. He sprang into the boat, and soon brought him to shore, but not until the vital spark had fled.—[Haverstraw Times.]

**A STRING OF PUNS, GOOD, BAD, AND INDIFFERENT.**—An auctioneer ought to be by nature strong; for, though only one man, he is often called upon to *knock down a lot*. Spring is welcome to the trees, because, they are *re-leaved* by its approach. Those persons who are in business the most *sharp*, usually get the most *blunt*. All blood may be said to be useless which is *in vein*. It is remarkable, that in music those strains please the most which are allowed to be *dull set*. The trade of a blacksmith is one of little labor to himself, inasmuch as most of his work is done by a *vice*. A statesman begins to *lower* himself when he consents to be *hired* by others. The additional day to February once in four years seems very naturally to increase the *spring* necessary for a *leap year*.—All persons who can *defer* their laughter until a convenient time, should be taken to the Humane Society, as extraordinary cases of *suspended animation*.—Those damsels who admire mustachios must be insincere in saying they dislike *hair lips*.—When people have *red hands*, they should always play at *loo*, as every thing is gained at that game by a *palm flush*.—Pugilists begin their battles from a paradox; for they stand up and *"fall to."*—James Eastman, the thief who tried to escape up the chimney, and was stopped by the grate, must have found a *great bar* to his rising.—In classing birds, we should say weather-cocks are meant for the *church*; but *hens* are decidedly the *lay* subjects of the state.

#### Extracts from Irving's *Abbotsford*.

**WASHINGTON IRVING'S FIRST BREAKFAST WITH SCOTT.**—On the following morning, after an early breakfast, I set off in a post chaise for the Abbey. On the way thither I stopped at the gate of Abbotsford, and sent the postillion to the house with my written introduction and my card, on which I had written that I was on my way to the ruins of Melrose Abbey, and wished to know whether it would be agreeable for Mr. Scott (he had not yet been made a Baronet) to receive a visit from me in the course of the morning.

In a little while the "lord of the castle" himself made his appearance. I knew him at once by the description I had read and heard, and the likeness that had been published of him. He was tall, and of a large powerful frame. His dress was simple, and almost rustic. An old green shooting coat, with a dog whistle at the button hole, brown linen pantaloons, stout shoes that tied at the ankles, and a white hat that had evidently seen service. He came limping up the gravel walk, aiding himself by a stout walking staff, but moved rapidly and with vigor. By his side jogged along a large iron-grey stag hound of a most grave demeanor, who took no part in the clamor of the canine rabble, but seemed to consider himself bound, for the dignity of the house, to give a courteous reception.

Before Scott had reached the gate he called out in a hearty tone, welcoming me to Abbotsford, and asking the news of Campbell. Arrived at the door of the chaise, he grasped me warmly by the hand: "Come, drive down, drive down to the house," said he, "ye're just in time for breakfast, and afterwards ye shall see all the wonders of the Abbey."

I would have excused myself, on the plea of having already made my breakfast. "Hoot man," cried he, "a ride in the morning in the keen air of the Scotch hills, is warrant enough for a second breakfast."

I was accordingly whirled to the portal of the cottage, and in a few moments found myself seated at the breakfast table. There was no one present but the family, which consisted of Mrs. Scott, her eldest daughter Sophia, then a fine girl about seventeen, Miss Ann Scott, two or three years younger, Walter, a well grown stripling, and Charles, a lively boy, eleven or twelve years of age, I soon felt myself quite at home, and my heart in a glow with the cordial welcome I experienced.—I had thought to make a mere morning visit, but found I was not to be let off so lightly. "You must not think our neighborhood is to be read in a morning, like a newspaper," said Scott. "It takes several days of study for an observant traveller that has a relish for auld world trumpery. After breakfast you shall make your visit to Melrose Abbey; I shall not be able to accompany you, as I have some household affairs to attend to, but I will

put you in charge of my son Charles, who is very learned in all things touching the old ruin and the neighborhood it stands in, and he and my friend Johnny Bower will tell you the whole truth about it, with a good deal more that you are not called upon to believe—unless you be a true and nothing-doubting antiquary. When you come back, I'll take you out on a ramble about the neighborhood. To-morrow we will take a look at the Yarrow, and the next day we will drive over to Dryburgh Abbey, which is a fine old ruin well worth your seeing"—in a word, before Scott had got through with his plan, I found myself committed for a visit of several days, and it seemed as if a little realm of romance was opened before me.

**The General Affection entertained for Scott.**—These simple anecdotes may serve to show the delightful play of Scott's humors and feelings in private life. His domestic animals were his friends; every thing about him seemed to rejoice in the light of his countenance: the face of the humblest dependant brightened at his approach, as if he anticipated a cordial and cheering word. I had occasion to observe this particularly in a visit which we paid to a quarry, whence several men were cutting stone for the new edifice; who all paused from their labor to have a "crack wi' the laird." One of them was a burghess of Selkirk, with whom Scott had some joke about the old song:

"Up wi' the Souters o' Selkirk,  
And down with the Earl of Home."

Another was precursor at the Kirk, and besides leading the psalmody on Sunday, taught the lads and lasses of the neighborhood dancing on week days, in the winter time, when out-of-door labor was scarce.

Among the rest was a tall, straight old fellow, with a healthful complexion and silver hair, and a small round crowned hat. He had been about to shoulder a hod, but paused, and still looking at Scott, with a slight sparkling of his blue eyes, as if waiting his turn; for the old fellow knew himself to be a favorite.

Scott accosted him in an affable tone, and asked for a pinch of snuff. The old man drew forth a horn snuff box. "Hoot, man," said Scott, "not that old mull: where's the bonny French one that I brought you from Paris?" "Troth, your honor," replied the old fellow, "sic a mull as that is nae for week days."

On leaving the quarry, Scott informed me that when absent at Paris he had purchased several trifling articles as presents for his dependants, and among others the gay snuff box in question, which was so carefully reserved for Sundays, by the veteran. "It was not so much the value of the gift," said he, "that pleased them, as the idea that the laird should think of them when so far away."

The old man in question, I found, was a great favorite with Scott. If I recollect right, he had been a soldier in early life, and his straight erect person, his ruddy yet rugged countenance, his gray hair, and an arch gleam in his blue eye, reminded me of the description of Edie Ochiltree. I find that the old fellow has since been introduced by Wilkie, in his picture of the Scott family.

**SCOTT AND HIS DOGS.**—Scott continued on, leading the way as usual, and limping up the wizzard glen, talking as he went, but as his back was towards me, I could only hear the deep, growling tones of his voice, like the low breathing of an organ, without distinguishing the words, until pausing, and turning his face towards me, I found he was reciting some scrap of border minstrelsy about Thomas the Rhymer. This was continually the case in my ramblings with him about this storied neighborhood. His mind was fraught with the traditional fictions connected with every object around him, and he would breathe it forth as he went, apparently as much for his own gratification as for that of his companion.

"Nor hill nor brook we paced along,  
But had its legend or its song."

His voice was deep and sonorous, he spoke with a Scottish accent, and with somewhat of the Northumbrian "burr," which, to my mind, gave a doric strength and simplicity to his elocution. His recitation of poetry was at times magnificent.

I think it was in the course of this ramble that my friend Hamlet, the black greyhound, got into a sad scrape. The dogs were beating about the glens and fields as usual, and had been for some time out of sight, when we heard a barking at some distance to the left. Shortly after we saw some sheep scampering on the hills, with the

dogs after them. Scott applied to his lips the ivory whistle always hanging at his button-hole, and soon called in the culprits, excepting Hamlet.—Hastening up a bank which commanded a view along a fold or hollow of the hills, we beheld the table prize of Denmark standing by the bleeding body of a sheep. The carcass was still warm, the throat bore marks of the fatal grip, and Hamlet's nostrils were stained with blood. Never was culprit more completely caught in flagrant delicto. I supposed the doom of poor Hamlet to be sealed; for no higher offence could be committed by a dog in a country abounding with sheep-walks. Scott, however, had a greater value for his dogs than for his sheep. They were his companions and his friends. Hamlet, too, though an irregular impetuous kind of youngster, was evidently a favorite. He would not for some time believe it could be he who had killed the sheep. It must have been some cur of the neighborhood, that had made off on our approach, and left poor Hamlet in the lurch. Proof, however, was too strong, and Hamlet was generally condemned. "Well, well," said Scott, "it's partly my own fault. I had given up covering for some time past, and the poor dog has had no chance after game to take the fire edge off of him. If he was put after a hare occasionally he never would meddle with sheep."

I understood, afterwards, that Scott actually got a pony, and went out now and then courting with Hamlet, who, in consequence, showed no further inclination for mutton.

**THE ORIGINAL OF EDIE OCHILTREE.**—A further stroll among the hills brought us to what Scott pronounced the remains of a Roman camp, and as we sat upon a hillock which had once formed a part of the ramparts, he pointed out the traces of the lines and bulwarks, and the pretorium, and showed a knowledge of antiquarianism, that would not have disgraced the antiquarian Oldbuck himself.—Indeed, various circumstances that I observed about Scott during my visit, concurred to persuade me that many of the antiquarian humors of Monk-harts were taken from his own richly compounded character, and that some of the scenes and personages of that admirable novel were furnished by his immediate neighborhood.

He gave me several anecdotes of a noted pauper named Andrew Gemmells, or Gemmel, as it was pronounced, who had once flourished on the banks of the Galia Water, immediately opposite Abbotsford, and whom he had seen, and talked and joked

with. I instantly recognized the r of philosophic vagabonds, Edie Ochiltree. I was on the name and recognizing collected the incognito ob-respect to the novels, and was one among many things me of his authorship.

Andrew Gemmells exactly ac-cite as to his height, carriage, well as his arch and mischievous, if home he had, was at Gal-lis "daundering" about the can show and beside the if walking chronicle through-Tweed, the Ettrick, and the

gossip from house to house, commenting on the inhabitants and their concerns, and never hesitating to give them a dry rub as to any of their foibles or follies.

A shrewd beggar like Andrew Gemmells, Scott added, who could sing the old Scotch airs, tell stories and traditions, and gossip away the long winter evenings, was by no means an unwelcome visitor at a lonely manse or cottage. The children would run to welcome him, and place his stool in a warm corner of the ingle nook, and the old folks would receive him as a privileged guest.

As to Andrew, he looked upon them all as a paragon does upon his parishioners, and considered the alms he received as much his due as the other does his tythes. I rather think, added Scott, Andrew considered himself more of a gentleman than those who toiled for a living, and that he secretly looked down upon the parading peasants that fed and sheltered him.

He had derived his aristocratic notions in some degree from being admitted occasionally to a pro-curious sociability with some of the small country gentry, who were sometimes in want of company to help while away the time. With these Andrew would now and then play at cards and dice, and he never lacked "miller in pouch" to stake on a game, which he did with a perfect air of a man to whom

money was a matter of little moment, and no one could lose his money with more gentlemanlike coolness.

Among those who occasionally admitted him to the familiarity, was old John Scott of Galis, a man of family, who inhabited his paternal manse of Torwoodlee. Some distinction of rank however, was still kept up. The land sat on the inside of the window and the beggar on the outside, and they played cards on the sill.

Andrew now and then told the land a piece of his mind very freely; especially on one occasion, when he had sold some of his paternal lands to build himself a larger house with the proceeds.—The speech of honest Andrew smacks of the shrewdness of Edie Ochiltree.

"It's a' varra weel—it's a' varra weel, Torwoodlee," said he; "but who would he thought that your father's son would be sold two gude estates to build a shaw's (suckoo's) nest on the side of a hill?"

[From the London Quarterly Review.]

#### MR. DE BEAUMONT ON THE AMERICANS.

M. de Beaumont speaks of himself as having travelled a good deal in England before he visited the United States. Yet in many of his criticisms on their manners and usages, he appears to be quite unconscious that he is spending his ingenuity on circumstances which he might have found in the old country just as well as in the new. The style of female education for example, which he expatiates upon through several chapters, is fundamentally the English one—and we hope no French criticisms will ever induce the Americans to lay it aside in favor of that which M. de Beaumont so sentimentally lauds. If this picture, however, be not grossly overcharged, our descendants have certainly pushed the ancient English plan to a rather hazardous extent, and all our Joe Miller stories about match-making mothers and aunts, and soft-eyed damsels who, nevertheless, keep an eye on the main chance, must fail to convey any adequate notion of the business-like sayings and doings of an American ball room. He says:—

"The women of America have a general cultivated mind, but little imagination, and more of sense than sensibility. The education they receive is entirely different from that which is given to their sisters in France. With us, the young girl remains till the day of her marriage under the entire protection of her parents—she reposes peaceful and unsuspecting, because near her there is a tender solicitude which watches and sleeps not—she has no need to reflect while there is another to think for her; she partakes the occupations and the sentiments of her mother, merry or sad, according as she happens to be at the moment—never beforehand with life, quietly gliding with its natural current. In America, she is free before she is adolescent—with no guide but herself, she treads, as at a venture, paths unknown to her feet. The first steps are the least dangerous—childhood traverses life as a light adrift plays without risk on a sea without rocks. But when the stormy billows of young passions are to be encountered, what is to become of that frail bark, with its swelling sails and inexperienced pilot? The education of America takes precautions against this danger: the fair maiden receives, at a very early period, full information as to the snares she will have to meet. Her instincts would be poor guardians for her; they place her under the protection of her reason—thus enlightened as to the allurement which are to surround her, she goes forth, trusting in herself alone for the means of escape. Her prudences never fail her. But all this deprives her of two qualities charming above every thing else in early youth— candor and simplicity. The young American female has need of knowledge to be virtuous—but she is too knowing to be innocent. This precocious liberty gives a serious turn to all her reflections, and stamps her character with something of the masculine.

"An excessive coquetry is, however, a trait common to all the young American girls, and it is also a consequence of their education. For every one who has passed her sixteenth summer, the one great interest of life is a marriage. In France, she desires it—in America, she seeks for it. In the midst of that all-busy society, where everybody has some positive material object in hand, she too has her concern—her business—her industry: it is to find a husband. The men about her are cold, chained to their worldly affairs—the most go to them—a powerful charm must be called in to attract them. Do not let us be surprised, then, if the

young girl who lives in the midst of them is prodigal of her studied smiles and tender glances: her coquetry is, to be sure, a well considered and prudent thing; she has measured the space within which she may play herself off—she knows the limit which she must not pass. Grant that her artifices are not in themselves to be applauded—you must at least allow that her aim is irreproachable—it is only to be married. Coquetry, with us, is a passion, in America, it is a calculation. Even if the young lady who has formed an engagement continues somewhat of her former procedure, this is a matter not of taste but of foresight. Her lover may break his faith: she is aware of this, and goes on gaining heart, from the wish, not to have two at a time, but to have a second in reserve in case the first should fail her.—Vol. i. p. 24.

M. de Beaumont, however, if he may be considered as a little too severe on the pretty damsel of the United States, does as ample justice as any other traveller to the undoubted purity of their manners. On this head, indeed, the reports of all the recent witnesses agree most completely—and to us most delightfully, for here again we are proud to say, we recognize the manners of England in those of her descendants. M. de Beaumont speaks, like a Frenchman as he is, about the old societies of Europe, as if they were all as corrupt on this score, as for aught we know the society of Paris may still be—but we need not enlarge upon a blunder which every English reader will at once trace to the right source. He tells us:—

"You may estimate the morality of any population, when you have ascertained that of the women; and one cannot contemplate American society without admiration for the respect which there encircles the tie of marriage. The same sentiment existed to a like degree among no nation of antiquity, and the existing societies of Europe, in their corruption, have not even a conception of such a purity of morals. In America, people are not more severe than elsewhere, as to the disorders and even the delicacies of single life; one meets with abundance of young men whose manners are notoriously dissolute, and who are thought none the worse of on that account. But society has no toleration for any tampering with conjugal faith; it is as inflexible towards the man who tempts as the woman who yields—both are banished from its bosom—and to meet this stern award it is not even necessary to be guilty; it suffices to have incurred suspicion.

"The morality of the American women, moreover, is protected by other circumstances. The man there, engrossed with positive interests, has neither the time nor the soul for tender sentiments and gallantries—he pays court once in his life—that is when he deems to arrange his marriage. The question then is, not an intrigue, but—a piece of business. He has not leisure to be in love, still less to be amiable. That taste for the fine arts, which blends so well with the enjoyments of the heart, is forbidden to him. To be suspected of any passion for Mozart or Michael Angelo would destroy him in public opinion. Condemned by the manners of his country to shut himself up within the dry circle of utility, the young American is equally devoid of the wish to please women and of the capacity to seduce them.—Vol. i. p. 25.

In a note on this passage he thus qualifies one of his statements:—

"It is true that one may meet here and there by accident with a young man whom the chances of a hereditary fortune and a polished education have qualified to take part in the intrigues and gallantries of society—but their number is so small that they can do no harm; and if they show but the slightest symptoms of a disposition to trouble the peace of a friend, the whole American world is at once in league to combat and crush the common enemy. This explains why American bachelors, with fortune and leisure, never remain in the United States, but come to live in Europe, where they find intellectual men and corrupt women.—Vol. i. p. 26.

The majority of his European readers will hardly thank our author for this last sentence. American bachelors with fortune and leisure pass rapidly through England—but we never heard of any such "rare bird" establishing his European room elsewhere than at Paris, Brussels, Rome, or Naples.

We are sorry to say that our next extract must be one of a less agreeable description. It refers to that popular indulgence for unfair bankrupts, which has already been adverted to in the discussion about M. Ludovic's proposed marriage with

## RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Term, \$3 a year, in advance. Previous volumes same price; full set of four volumes, \$12.

## RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$2.

## MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, in advance. Previous volumes \$1.50 each.

## THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY-THREE for \$10. D. K. M.

## NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

## QUARTERLY JOURNAL OF AGRICULTURE, MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$5, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 220 pages.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher, D. K. MINOR, 35 Wall street, New-York.

## PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to. HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.

Spikes are kept for sale, at factory prices, by J. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 223 Water street, New-York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; Degrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

122am

H. BURDEN.

## PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-11

## TO TUNNEL MINERS, DRILLERS, &amp;c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-4f

## BLOSSBURG AND PAINTED POST RAILROAD, OR TIOGA NAVIGATION COMPANY.

By an Act of the Legislature of the State of Pennsylvania, passed the 14th day of April, 1835, five per cent. interest is guaranteed to the Stockholders of said Company for the term of twenty years.

The books for subscription of the above Stock will be opened at the Exchange in the City of New-York, on Monday, the 22d day of June inst., where one or more of the Commissioners duly authorized will attend.

## PUBLIC NOTICE.

THE undersigned, Commissioners for the amelioration of the navigation of the Richelieu or Chambly River, will receive at their office, in the borough of St. Denis, on the 15th of June next, sealed propositions for the construction or erection of a Dam or Causeway, with a Lock; to be erected about three miles above the village of St. Ours, either in Cut Stones, Common Stones, Pierres Brutes, or in Wood, according to the plans and specifications made by W. E. Hopkins, Esqr., Engineer, deposited, and where they can be seen at any time, in the hands of Joseph Cartier, Esqr., one of the said Commissioners, at St. Antoine.

All propositions addressed by the mail must be sent free of postage.

Two good securities will be required for the due execution of the aforesaid works.

Further information can be had at any time, from the undersigned, in addressing them at their respective residences, or from the said W. E. Hopkins, Esqr., at Bunker's Hotel, at the Chambly Basin.

ROCH DE ST. OURS, at St. Ours.  
JOSEPH CARTIER, at St. Antoine.  
JOS. T. DROLET, at St. Marc.  
L. C. DUVERT, at St. Charles.  
L. F. DESCHAMBAULT, at St. Denis.

Office of the Commissioners, St. Denis, May 11, 1835. 20-4t

The above Dam and Lock are in dimensions as follows: Lock 200 feet, Chamber 50 feet wide; Dam 675 feet long, 8 feet high.

## RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-1y feb14

## STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads.

No. 264 Elizabeth street, near Blissock street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J36 1f

## NOTICE TO MANUFACTURERS.

SIMON FAIRMAN, of the village of Lansingburgh, in the county of Rensselaer, and state of New-York, has invented and put in operation a Machine for making Wrought Nails with square points. This machine will make about sixty 6d nails, and about forty 10d nails in a minute, and in the same proportion larger sizes, even to spikes for ships. The nails are hammered and comes from the machine completely heated to redness, that its capacity for being cleached is good and sure. One horse power is sufficient to drive one machine, and may easily be applied where such power for driving machinery is in operation. Said Fairman will make, vend and warrant machines as above, to any persons who may apply for them as soon as they may be made, and on the most reasonable terms. He also desires to sell one half of his patent right for the use of said machines throughout the United States. Any person desiring further information, or to purchase, will please to call at the machine shop of Mr. John Humphrey, in the village of Lansingburgh. August 15, 1833. A39 MF & Rf

## RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

## PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMASTURNER, at the Factory, Troy, N. Y. sept 13-1v

## RAILWAY IRON.

96 tons of 1 inch by 1/2 inch.	Flat Bars in lengths of
300 do. 1 1/2 do. do.	14 to 18 feet, counter sunk
40 do. 1 do. do. do.	holes, ends cut at an angle
800 do. 2 do. do. do.	of 45 degrees, with split
800 do. 3 do. do. do.	Wag plates and nails to
	soon expected.

350 do. of Edge Rail of 36 lbs. per yard, with the requisite chairs, kevs and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2 1/2, 3, 3 1/2, 3 3/4, and 3 1/2 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d7lmeowr

## SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

J21 6t

## SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1833.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sight, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1833.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1833.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad.

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JUNE 20, 1835.

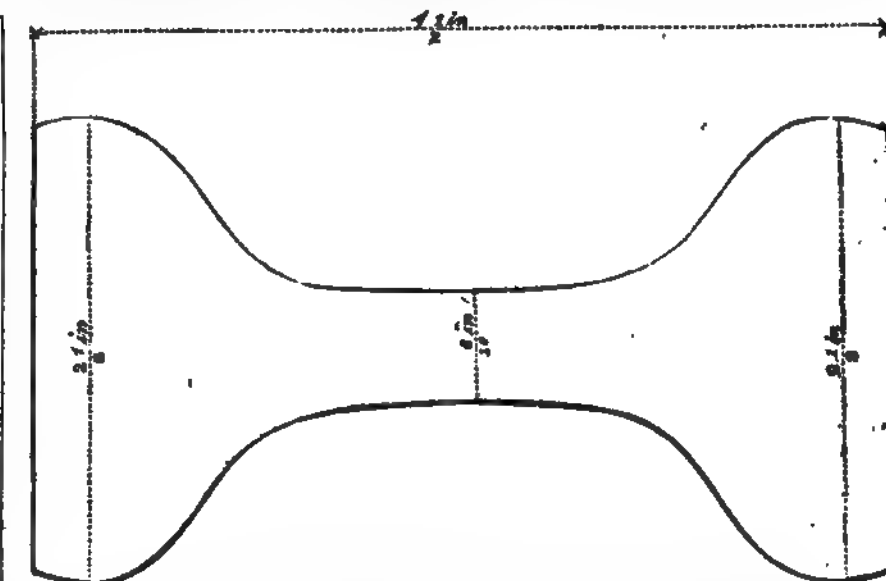

We have been again favored by Mr. G. RALSTON, of Philadelphia, now in London, with an interesting letter, from which we make the following extract; and we take this method of returning our thanks for the numerous favors conferred upon us and our readers, by Mr. Ralston, in forwarding early accounts of improvements in the construction of railroads and railroad machinery. He will please to accept our especial thanks for the Report of Dr. Barlow, "on the transverse strength and other properties of malleable iron," of which we shall endeavor to give a full account in our next number; and also for the papers on "Pneumatic Railways," one of which, containing the opinion of Professor Faraday, and Dr. Lardner, will be found in this number.

Of this "new plan" we confess that we are not able to form an opinion, as we have time only to print, not to read it. We shall take time to read the other before it is published, and hope then to be able to give a more correct idea of the project than we now possess.

Extract from a Letter, dated

London, May 12, 1835.

Dear Sir,—I observe by the "American Railroad Journal," which I received from New-York yesterday, that you have published two papers which Mr. Robert Stephenson kindly allowed me to copy from his original MS., and which I sent to the "Journal of the Franklin Institute" in Philadel-

phia. These articles are, 1st, Mr. S.'s Report on the "Undulating Railway System," and 2d, his "Remarks on the best form for Railway Bars."

I am very much pleased that you insert matter of such excellent quality in your useful Journal, and to enable you to continue the subject "of the best form of rail," I beg you will accept a book I send herewith, being a Report and Appendix made by Professor Barlow to the London and Birmingham Railway Company on this subject. You will observe that he controverts Mr. Stephenson's arguments in favor of "fishbellies," and gives a decided preference to parallel rails. I think this report will please your numerous readers. I must call your attention to the circumstance that, on the Liverpool and Manchester Railway, they are now taking up (as rapidly as is convenient) the fishbellies of 35 lbs. per yard, and laying down in their place parallels of 60 lbs. per yard. You know the increase of weight of locomotives on this road is very considerable; they formerly weighed 4 or 5 tons—they now weigh 10, 11, and 12 tons. So also on the Stockton and Darlington Railway, the rails originally weighed 25 lbs. per yard; they have removed them, and substituted rails of 45 lbs. per yard. On all the railways in use, or being constructed in this country, they consider heavier lo-

comotives, and of course stronger rails, as most expedient and economical. Enclosed I send you a tracing of the new rail for the "Grand Junction Railway," (from Birmingham to Warrington, to make the connexion, by railway, from London to Liverpool.) [See accompanying figure.] You will observe that it is a parallel rail, of 60 lbs. per yard, and that it is somewhat in form of Mr. Robert Stephenson's (our distinguished countryman) T rail—having as much base, which rests upon the ground, as surface for the wheel to run upon. The Engineer of this railway is Sir George Stephenson, (lately knighted by the King of the Belgians,) the father of Mr. Robert Stephenson; who is the Engineer of the Birmingham and London Railway. These two eminent men being in habits of constant intercourse, I think it highly probable that this form of rail has been adopted with the sanction of both of them; and if it be so, the fishbellies will never come into favor again.

I also send you two papers on the "Pneumatic Railway System," contrived and patented by our countryman, Mr. Pinkus, of Philadelphia. The shares for the Company have all been taken with great eagerness, and a line of a few miles in length is to be immediately laid down near London, for the purpose of testing its practicability and utility. The members of the association, as

well as many others, are very confident of success; but we shall soon see whether it will answer as well in practice as it promises in the working model.

I am very much pleased that you advocate with so much ability and zeal that magnificent project, a railway from the Hudson to Lake Erie. I read your articles with deep interest, and hope your judicious exertions will be crowned with success. As I am in the midst of railway iron, locomotives, and persons connected with all projects of internal improvements, I will be happy to serve you, or the readers of your excellent Journal, by procuring information, or in any other way that may be pointed out to me as acceptable.

I am, very respectfully,  
Your most ob't serv't,  
GERARD RALSTON.

#### PNEUMATIC SYSTEM OF RAILWAY.

Royal Institution, 3d Feb., 1835.

My Dear Sir,—The points in your letter of the 26th of last month, which you put to me for an opinion, are such that I have no hesitation in agreeing with you upon them.

To enumerate briefly these points:—the principle of communication of power is correct; the use of local steam engines is highly advantageous, both for cheapness of force and capability of varying it when required; the necessity for levels will, I presume, therefore be greatly obviated; the association of cylinder and rails is such, that the whole road must (with sufficient thickness in the cylinder) have great strength and firmness; the absence of locomotive engines removes much of the cause of derangement which the road would have to sustain; and I do not see how the governor and carriages can leave the railway.

You know my objection to giving a general opinion in reference to the profitable application of the plan in question; but I may here add, that the reserve I feel originates simply in my possessing no practical knowledge of the construction, expense, and profit, of ordinary railroads.

I am, my dear Sir, very truly yours,  
M. FARADAY.  
Wm. Hosking, Esq., F. S. A., &c.

#### Opinion of Dr. Lardner upon the Pneumatic System of Railway.

I have read the specification of the patent for the pneumatic railway and the accompanying papers, and have also examined the drawings and models which have been submitted to me by Mr. Hosking.

Two methods have been heretofore employed for rendering steam power available in transport upon railways; one by causing a travelling or locomotive engine to move with the load which it draws, the other by constructing, at intervals of about a mile and a half, stationary steam engines, the power of which is transmitted to the load by a rope carried along the road upon rollers or sheaves placed between the rails. The train being attached to this rope, is drawn by the power of the engines from station to station. The object of the pneumatic railway is to substitute for the rope a partially-exhausted tunnel; to employ the fixed steam engines to work air-pumps, by which a rarefaction of the tunnel shall be maintained; and to cause the trains to be tracked upon the railway by connecting them with a diaphragm or piston placed in the interior of the tunnel, so as to have that part of the tunnel in advance of the piston entered by the engines, while that part behind the piston is open to the atmosphere. An effective impelling power is thus obtain-

ed equivalent to the difference between the pressure of the atmosphere on one side of the diaphragm and of the rarefied air on the other.

Of the practicability of this project I think there can be no doubt. The working of large air-pumps by an adequate moving power, and the rarefaction of air in tubes or tunnels by such means is not a new idea. It was suggested by Papin, in the latter end of the seventeenth century, and was even pointed out by him as a means of transferring power to a distance, without the loss by friction and other causes consequent upon the use of ropes or other ordinary means of transmitting force.\* It is, in fact, a well understood principle in physics, that whatever moving force be expended in producing the rarefaction of air in a cylinder or tunnel, must necessarily be followed by a corresponding force on the other side of a diaphragm moving air-tight in that tunnel, and exposed to the free action of the atmospheric pressure. In the present case, supposing the structure of the valvular cord and the pneumatic piston to be perfect, the opposite side of the diaphragm will always be pressed by an effective impelling force, the amount of which may be calculated upon these principles. It will of course be perceived that no original moving power is obtained from the tunnel, or from the rarefied air; the rarefaction gives back the power expended by the stationary engines and nothing more; and the tunnel must therefore be regarded merely as a substitute for the ropes in the common method of working railways by stationary engines. But it is evidently attended with several advantages in comparison with the latter. A very large proportion of the moving power of stationary engines worked by ropes is intercepted by the resistance from the weight and friction of the ropes, sheaves, barrels, drums, &c. All such waste of power is removed by the pneumatic tunnel.

The original expense of ropes and their wear and tear would be likewise saved. Some notion of the extent of this saving may be collected from the following facts: when the Liverpool and Manchester railway was about to be brought into operation, a question arose as to the expediency of working it by stationary engines, and estimates of the expense were made by competent engineers. The total amount of capital to be invested in moving power was estimated at about £120,000; of this above £25,000 was devoted to ropes, sheaves, drums, and other necessary accompaniments. The total annual expense of maintaining the moving power was estimated at £42,000, and of this about £18,000 was appropriated to the wear and tear of ropes, sheaves, &c. Thus it appears that the method of transmitting the power of the stationary engines to the trains by ropes would absorb about 30 per cent. of the invested capital, and their maintenance would consume about 43 per cent. of the annual expenditure.

Another source of comparative economy would obviously be the diminished number of stationary engines. In the estimate already referred to it, was calculated that the distance of 30 miles should be divided into 17 stations, with two 40 horse engines at each station; besides these there would have been two engines at the bottom of each inclined plane, one at the tunnel, two at the top of the planes, and one at the Manches-

\* Papin proposed to obtain an active force at one end of an exhausted tube by the application of water power at the other.—W. H.

ter end, making in all 42 stationary engines to work a line of 30 miles. Now, according to the estimate of the patentee of the pneumatic railway, from three to six stations would be sufficient between Manchester and Liverpool, and the whole line would be worked by from six to twelve steam engines. Putting aside therefore the saving of power which would arise from the substitution of suction in the tunnel for ropes, and supposing the amount of stationary power in both cases to be the same, it will be evident that a material saving would arise from the circumstance of that amount of power being derived from so much less a number of engines,—the number of engine-men, assistants, &c., besides the interest on capital, being considerably less.

Some notion of the economy of power likely to arise from superseding the use of ropes may be collected from the result of experiments made by Messrs. Stephenson and Locke on the resistance arising from the friction of ropes. They found that a load of 52 tons drawn by stationary engines worked by ropes through mile and half stages, offered a total resistance amounting to 1156 lbs.; of this 582 lbs. arose from the friction of the load, and 574 lbs. from the friction of the ropes. In the case of the pneumatic railway, the friction of the rope is replaced by the friction of the air-pumps and of the impelling apparatus, and it will be evident that the latter, compared with the former, must be almost insignificant. Hence the power wasted in its transmission from the stationary engines to the load, which in one case amounts to 50 per cent. of the whole moving power of the engine, in the other is of comparatively trifling amount.

Slopes on railways will always be objectionable whatever power be used; for even the most gentle ascent will increase the resistance of the load in an enormous proportion. The difficulties, however, which they present are materially less when the line is worked by stationary than by locomotive engines, and would be still further diminished by superseding the rope; the resistance arising from the rope being always greater on inclined planes than on the level, owing to its increased thickness and consequent weight. A load which requires a 4½ inch rope for the level requires a 5½ inch rope upon a slope of 1 in 100. The weights of equal lengths of these ropes would be in the proportion of about 2 to 3, the slope requiring one-half more weight of rope than the level. Besides this, the moving power on a slope, in addition to the ordinary friction which it has to overcome on the level, has likewise to draw up the weight of the rope,—a resistance which will be increased in proportion to the acclivity of the slope.

The disadvantages produced by slopes when locomotive engines are used are still more formidable. The same engine which is fitted to work upon the level is altogether inadequate for the slopes, the consequence of which is, either that the locomotive is strained beyond its power by working up the slopes, and rapidly destroyed, or that the engines must be more powerful than is requisite for the common level of the road, and thus power and expense wasted; or finally, that an auxiliary engine must be kept constantly ready at the foot of each slope, with its fire lighted and its steam up, ready to help up the trains as they arrive. Unless the trains be almost incessant (which, even on the most frequented railroad, they never can be,) this last expedient, which is the one adopted on the Manchester line, is attended with great waste of power and

expense. Stationary engines worked on the pneumatic principle would effectually remove all these difficulties and objections.

The weight of the trains which could be drawn upon the pneumatic railway, and the speed of the motion imparted to them would entirely depend upon the power of the stationary engines. As the friction or other resistance does not increase with the velocity, the same absolute expenditure of power would draw the same load at whatever speed. The high speed attained by locomotive engines has been attended with great expense, but this has not arisen from the increased expenditure of power. It has been caused by the wear of the engines themselves consequent on their rapid motion on the road, and by the necessity of sustaining a fierce temperature in the fire-place in order to be able within the small compass of these engines to generate steam with sufficient rapidity to attain the necessary rate of motion. As the magnitude of the stationary engines would not be limited, and as they would not be subject to the injurious effects of motion on the road, steam could be produced in sufficient quantity for the attainment of any required speed, without increasing its cost, or in any way impairing the machinery.

One of the obstacles to the attainment of great speed by stationary engines worked by ropes, is the delay produced in transferring the trains from engine to engine, and from station to station. The momentum imparted to them is lost at each change, and these changes occur every mile and a half, so that the train has scarcely attained its requisite speed, when its motion must again be checked in order to hand it over to another engine. This difficulty is removed by the pneumatic system: there being no rope to be detached and attached, the engine passes on by its momentum from station to station, and a contrivance is provided by means of a valve at the stations, by which it is brought under the operation of the next engine without stopping its motion.

Although the danger of accidents to passengers on the present railways worked by locomotive engines is considerably less than that of travelling by horse coaches on turnpike roads, yet serious accidents have occasionally occurred. These have generally arisen either from the locomotive engine running off the rails, from one train running against another, from the locomotive engine breaking, or, finally, from persons standing upon the rails being run down. In the pneumatic system there is almost a perfect security from these causes of danger. From the engines being stationary, and the tunnel rising between the wheels of the trains, it is evidently impossible for the carriages to run off the road; and from the manner in which the system is worked, it is impossible that one train can run against another. It happens also that the nature of the rails themselves, forming, as they do, merely ledges upon the sides of the tunnel, prevent the possibility of persons standing between or upon them.

In railways worked by stationary engines, serious accidents have occasionally occurred by the ropes breaking, while the train has been ascending a slope. In such cases the train has run down by its weight with a frightful rapidity, producing the destruction of the carriage, and the loss of life. It is evident that this source of danger is removed by the pneumatic system.

An advantage possessed by this system above the edge railroad, deserves to be particularly noticed. In the edge railroad, the

engines and carriages are kept upon the road by flanges, or ledges, raised upon the tires of the wheels, which press on the interior of the rails. Every thing which causes the carriages to press on the one side or the other, causes these flanges to rub against the rails. When a curve or bend happens in the road, the carriages are guided by the pressure of one or the other flange on the side of the rail, which of course is accompanied by considerable friction. In the pneumatic railway there are no flanges, either on the wheels or rails; the carriages are guided by wheels, or rollers, placed in a horizontal position, and acting upon the external sides of the channel which receives the valvular cord. By this means all resistance which arises from what is called rubbing friction, is removed, and every surface which moves upon another, moves upon it with a rolling motion.

It is well known, that notwithstanding the prosperous condition of the Manchester Railroad Company, yet their expenditure as a locomotive power has been so enormous as to cause considerable anxiety on the part of the managers, and some of them have even inclined to the opinion, that the question of stationary power deserves to be reconsidered. This opinion would probably be confirmed and strengthened, if the practicability of the pneumatic system were satisfactorily demonstrated by experiment upon a sufficiently large scale.

On the whole, it appears to me that if the mechanical difficulties of maintaining the pneumatic tunnel sufficiently air tight be overcome, the system presents a fair prospect of being practically successful. These difficulties are not so great as they may at first appear. It should be recollected, that nothing approaching to the exhaustion of the tunnel can be necessary; nor even any considerable degree of rarefaction. Supposing the tunnel to have an internal diameter of 40 inches, the impelling diaphragm would have a surface of about 9 square feet. If in such a tunnel a degree of rarefaction were produced, sufficient to cause a barometric gauge to fall two inches, (which would be an extremely slight degree of rarefaction indeed,) an impelling force would be obtained amounting to one pound on every square inch of the surface of the diaphragm, which would give an impelling force of more than half a ton. It is calculated, that on the common railways the amount of load is above 200 times the force of traction, and it would therefore follow, that this force would be sufficient to draw a load of 100 tons. If an additional inch of mercury be made to fall in the barometric gauge to balance friction, &c. still the rarefaction would be extremely inconsiderable, and the contrivances to prevent leakage would appear to be attended with no great mechanical difficulty.

From the various reasons which I have above stated, I am of opinion that the present project would, if carried into execution, be likely to be attended with greater economy and safety than any other method of working railways now practised; and I see no reason against the attainment of as much speed as is obtained by the locomotive engines. At all events, having explained the reasons on which I have grounded this opinion, every one can judge to what weight it may be entitled. The project would appear to be well deserving of trial on some railroad of limited length, such as that between London bridge and Greenwich, where it would be sufficient to have stationary engines at the extremities. In such a case, I see scarcely any limit to

the speed which might be attained with safety; and the economy, as compared with locomotive engines, would probably be very great.

DION. LARDNER.

London, Feb. 19, 1855.

[For the Railroad Journal.]

#### LOCOMOTIVE STEAM ENGINES.

The friends of the resolution for taking off the duties from locomotive steam engines, which was brought forward during the last session of Congress, urged in support of that measure the incompetency of the workshops of this country to supply the demand, and the inferiority of American locomotive engines.

It may be interesting to some of your readers to learn how little this argument is supported by the facts of the case. In a visit to the workshop of Mr. M. W. Baldwin, of Philadelphia, from which I have just returned, I collected the following information: Mr. B. has delivered from his workshop, within the last twelve months, ten locomotive steam engines, has six now in his shop in a state of great forwardness, some of which are nearly completed, and has contracts on hand for about twenty engines, for the following roads, viz.: the Columbia, Pa., State Road; the Trenton, the Newark, the Jamaica, the Troy and Saratoga, and the Utica and Schenectady roads. Under his present arrangements, he informed me that he gives employment to about 150 persons, and is able to complete an engine about every three weeks; and, to meet the increasing demand, is erecting workshops which will accommodate 500 hands.

As regards the character of these engines, there are seven of them at work on the Pennsylvania State road, upon which they have also two English engines, from the workshop of their most celebrated maker, R. Stephenson.

The engineer who has charge of the locomotive department on this road, informed me that the power of the American engines is about 95 per cent. greater than that of the English, and that the loss of time, and cost for repairs, is altogether in favor of the American engines: five hands, as he stated, having been sufficient to keep all the seven in order.

For the gratification of such of your readers as are interested in railroads, I will refer to the principal points of difference between the English and American engines; and what I conceive to be the peculiar advantages of the American engine.

It is well known, that the crank-shaft, and the wheels, of the locomotive engine, have been by far the most troublesome and expensive part of the machine to be kept in repair. By the improvements in Mr. B.'s engine, these difficulties have been obviated, as has been proved by experiment. Of the 7 engines on the state road, and 2 on the Trenton road, some have been at work since the 1st of July last, and in no instance has a crank broken, or worked loose, or any of his improved wheels failed, or given trouble.

It is here proper to observe, that the Pennsylvania road is almost a continued series of curves, ranging from 500 to 700 feet radius, and so severe is it upon the wheels of an engine, that one of the English engines, (the other having been out of repair most of the time,) has within 2 months used up or destroyed a part of the wheels of both engines, and is now using a set of Mr. Baldwin's wheels.

The other improvements affect the force-pump, eccentrics, and reverse gear, all of

which are so much simplified that the joints and working parts are not more than half as numerous as in the common English engine. The steam pipes have all ground metallic joints, and no cement or soft solder is used in any of the joints of the engine.

Another very important improvement has been added, by which the adhesion of the driving wheels may be increased at will, from 35 to 50 per cent. By this means, one of these engines, with only 6487 lbs. on her driving wheels, as a fixed weight, has carried a gross weight of 80 tons up an inclination nearly two miles in length, of 35 feet per mile ascent, without any perceptible slipping of the wheels.

The great object of the whole of these improvements has been to strengthen the weak points in the machine, and to simplify and reduce the number of its parts; and so fully has this object been accomplished, that this engine may justly be considered the most perfect of its kind now in use.

A FRIEND TO AMERICAN MANUFACTURES.

New-York, June 16, 1835.

The following gentlemen were elected Directors of the Long Island Railroad, on Tuesday last. It is a list of names, we need not say, which will insure the speedy construction of the road:

Knowles Taylor, Samuel Hicks, John Delafield, John L. Graham, Henry Wyckoff, Benjamin Curtis, Morgan L. Smith, George D. Strong, of New-York; William F. Blydenburgh, Joshua Fanning, William Sydney Smith, of Suffolk county; Clarence D. Sackett, of Kings county; and Valentine Hicks, of Queens county.

At a subsequent meeting of the Board of Directors the following officers were unanimously chosen:

Knowles Taylor, President; William F. Blydenburgh, Vice President; John Delafield, Treasurer and Register; Jon L. Graham, Counsel and Attorney; and Clarence D. Sackett, Secretary.

**RAILROAD TO QUEBEC.**—The Board of Aldermen and the Common Council of the city of Portland, have passed in concurrence an order which provides for the appointment of an Agent to attend the survey of a contemplated route of the Railroad from Quebec to Portland, to procure the assistance of gentlemen of that city and elsewhere, who feel an interest in making the harbor Portland the point at which it shall terminate, to ascertain its practicability, the best route, and all interesting facts appertaining to the subject.

It is stated, upon what we presume to be good authority, that the receipts of the Camden and Amboy Railroad Company, were ninety thousand dollars in the month of March last! This month is by no means one of the best in the year for the business of transportation; and it would be safe, therefore, to assume that the receipts of that company will exceed a million this year!—[Frederic.]

Extract of a Letter dated Chicago, June 5, 1835.

DEAR SIR—I arrived here, early in May, in good health—and on the 2d of June received the remainder of the boxes and packages forwarded from New York on the 30th of April—a part of them having arrived on the 25th May. This delay is owing, mainly, to the ice, which so long blockaded the port of Buffalo. Merchants here have not yet received all their goods—although those at Peoria, about one hundred miles from here, have had theirs, by the way of Philadelphia, six weeks. When our canal to Peoria shall be completed, we shall be able to receive all our goods from Philadelphia, through Pittsburgh, the Ohio and Illinois river and canal, earlier than by Lake Erie, unless there is any other channel than the New York canal.

*On the Location of Railroad Curvatures; being an Investigation of all the Principal Formulas which are required for Field Operations, in laying Curves and Tangent Lines, to pass through Given Points.*  
By J. S. VAN DE GRAAFF. [For the American Railroad Journal.]

[Continued from Number 22.]

26. Let the characters  $\alpha$ ,  $n$ ,  $m$ ,  $T$ , and  $T'$ , represent the same things as in the preceding article, and suppose the conditions with relation to the curves ADF, and BMR, to remain. Produce the two tangents FA, and RB', until they intersect each other; and take  $v$ , and  $v'$ , to denote the number of chains in each respective tangent to their common point of intersection, and let  $z$  represent the angle of intersection. It is then proposed to investigate the general equations which subsist among those various quantities, in order that, when the circumstances in the field are such as to make any one of the quantities  $\alpha$ ,  $m$ ,  $T'$ ,  $v'$ , or  $z$ , unknown, that quantity may then be eliminated, and its value obtained.

The first equation which will be required, in the investigation of any case where the intersection of two tangents is concerned, may be immediately deduced from (V.), and is expressed as follows:

$$2nT - 2mT' - z = 0 \quad (\text{XXXI.})$$

And thus any one of the three quantities  $m$ ,  $T'$ , or  $z$ , will be made known, when the other two are given, or assumed in such a manner as the situation of the ground may require. If, however,  $z$  be a quantity whose value is given, and fixed by particular circumstances in the field, then the value of  $T'$  should generally be taken in such a manner as to give  $m$  an integer number, when eliminated from the equation  $2nT - 2mT' - z = 0$ .

The second subject of inquiry will now be an investigation of such equations as express the relations which exist between the quantities  $\alpha$ ,  $v$ , and  $v'$ . In the case here under consideration, it is evident from (XXIX.), that  $X + \alpha - X' + Y - Y' = 0$ ; and therefore, agreeably to the principles of algebra,  $X + \alpha - X' = 0$ , and  $Y - Y' = 0$ ; that is,  $\alpha + v + v' \cdot \cos. 2mT - x' - v' \cdot \cos. 2mT' = 0$ , and,  $y + v \cdot \sin. 2nT - y' - v' \cdot \sin. 2mT' = 0$ . From the last of these two equations, let the value of  $v'$  be obtained, and substituted in the first. The result is,  $\alpha \cdot \sin. 2mT' - v \cdot \sin. z + x - x' \cdot \sin. 2mT' - y - y' \cdot \cos. 2mT' = 0$ ; and in like manner,  $\alpha \cdot \sin. 2nT - v' \cdot \sin. z + x - x' \cdot \sin. 2nT - y - y' \cdot \cos. 2nT = 0$ . But by (VII.),  $x - x' = \frac{\sin. 2nT}{2 \sin. T} - \frac{\sin. 2mT'}{2 \sin. T'}$ , and,  $y - y' = \frac{1 - \cos. 2nT}{2 \sin. T} - \frac{1 - \cos. 2mT'}{2 \sin. T'}$ ; which values being substituted in the last equations, and the obvious reductions made, the two following equations will result:

$$\alpha \cdot \sin. 2mT' - v \cdot \sin. z + \frac{\cos. z - \cos. 2mT'}{2 \sin. T} - \frac{1 - \cos. 2mT'}{2 \sin. T'} = 0;$$

$$\alpha \cdot \sin. 2nT - v' \cdot \sin. z - \frac{\cos. z - \cos. 2nT}{2 \sin. T'} + \frac{1 - \cos. 2nT}{2 \sin. T} = 0. \quad (\text{XXXII.})$$

Such is the second system of equations which will be required in the field.\* The

\* In order to avoid misapprehension and error, particular attention must be paid to the sign of the angle  $z$ , which, in all cases where  $2mT'$  exceeds  $2nT$ , is to be made negative; or, the angle  $z$  is to be accounted negative, when the tangent  $v'$  is more inclined than  $v$ , to the common tangent at the origins.

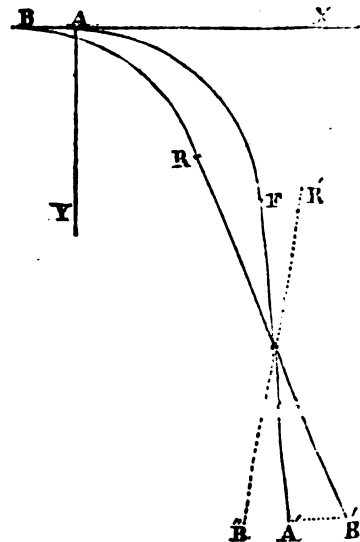

following cases may be given to illustrate their application:

Case I. When  $v$ ,  $z$ , and  $T'$ , are given, to find  $\alpha$ .

Here, by an evident transposition of the first of the equations (XXXII.), the following formula is obtained:

$$\alpha = \frac{v \cdot \sin. z + \frac{1 - \cos. 2mT'}{2 \sin. T'} - \frac{\cos. z - \cos. 2mT'}{2 \sin. T}}{\sin. 2mT'} \quad (\text{XXXIII.})$$

And the quantity  $\alpha$  thus becomes known; for the value of  $m$  may be obtained from (XXXI.). In every instance in which this case will occur in practice, such a value may be selected for  $T'$ , as will give  $m$  an integer number, without doing any injury to the line.

Example 1. Let AX be a given tangent line, and A a given point therein, selected for the origin of a curve. By means of a system of rectangular lines, traced from the origin A, and parallel to the axes AX, AY, let a certain point F be designated, as the situation of the ground may seem to require, and in such manner as to coincide with the extremity of the 25th chain of a curve AF, whose modulus of curvature is  $1^\circ 30'$ , agreeably to the method explained, art. 17. From the point F, let a tangent FA be traced 60 chains, agreeably to the principles given in art. 16; and from the point A' trace the rectangular ordinate A'B', 2.5 chains, to a point B', selected in consequence of the particular situation of the ground. Now, suppose S to be a point in the tangent line FA', 30 chains from F, through which the peculiar situation of the ground renders it desirable that a new tangent RSB' should be laid. It is then proposed to determine the position of such a point B, in the primitive tangent AX, as will be the proper origin of a new curve BR, passing into the proposed tangent line RSB'.

It is here supposed, as the figure indicates, that the line RSB' has an inclination, less than the line FSA' to the common tangent AX; and consequently, in this instance, the angle  $z$  will be positive, and expressed by the angle A'SB'. By plane trigonometry,  $\tan. z = \frac{A'B'}{A'S} = \frac{2.5}{30} = .08333$ ;

or,  $z = 4^\circ 46'$ . Hence, by (XXXI.),  $2mT' = 2nT - z = 75^\circ - 4^\circ 46' = 70^\circ 14'$ ; or,  $mT' = 35^\circ 7'$ . Now, the values of the quantities  $m$  and  $T'$  may be taken in any arbitrary manner, provided the equation  $mT' = 35^\circ 7'$  be satisfied. The peculiar situation of the ground, between the points A and F,

must therefore *decide* the values of  $m$ , and  $T'$ . The object should be to make the new curve BR as long as the limits of expense will allow; for in the same proportion as that curve is made longer, it will also be made of less abrupt curvature; but it will then diverge farther to the right of the first curve AF. Let it be supposed that the new curve BR may have a length of 20 chains; then,  $T' = \frac{35^\circ 7'}{20} = 1^\circ 45'$ , which will therefore be the modulus of curvature of the new curve BR. And now, to find the necessary position of the origin B, we have, by (XXXIII.),

$$\alpha = 30 \times \sin. 4^\circ 46' + \frac{1 - \cos. 70^\circ 14' - \cos. 4^\circ 40' - \cos. 70^\circ 14'}{2 \sin. 1^\circ 45' - 2 \sin. 1^\circ 30' \sin. 70^\circ 14'}$$

That is,  $\alpha =$

$$30 \times .06310 + \frac{-.66181 - .99654 - .33819}{-.94108} =$$

$$2.493 + 10.800 - 12.573 + .720 = .765.$$

Hence, measure the distance AB = .765 of a chain, back upon the tangent line AX, and the required origin of the new curve BR will be obtained.

Example 2. Suppose the same data to remain as in the preceding instance, with the exception only that the position of the required new tangent R' S B', is reversed; that is, let the line R' S B' have an inclination exceeding that of the line FSA', to the common tangent AX.

Here the angle  $z$  becomes *negative*, and therefore, by (XXXI.),  $2mT' = 2nT - z = 75^\circ + 4^\circ 46' = 79^\circ 46'$ ; or,  $mT' = 39^\circ 53'$ . And hence, if it be supposed that the ground between the points A and F be such as to admit a new curve 40 chains in length, then  $T' = \frac{39^\circ 53'}{40} = 0^\circ 59\frac{1}{2}'$  = modulus of curvature of the new curve. Now, recollecting that  $\sin. z$  becomes *negative*, and  $\cos. z$  remains *positive*, we have

$$\alpha = -30 \times \sin. 4^\circ 46' + \frac{1 - \cos. 79^\circ 46' - \cos. 4^\circ 46' - \cos. 79^\circ 46'}{2 \sin. 59\frac{1}{2}' - 2 \sin. 1^\circ 30' \sin. 79^\circ 46'}$$

$$= -2.493 + \frac{-.82234 - .99654 - .17766}{-.96409} =$$

$$-2.493 + 23.630 - 15.637 = + 5.500$$

5.50. Hence, the new origin is 5.50 chains, back upon the tangent line AX; and consequently, in this instance, the new curve will intersect the first curve AF.

Case II. When  $\alpha$ ,  $v$ , and  $z$ , are given; to find  $T'$ .

Let the quantity  $2mT'$  be represented by  $D$ ; and the following expression will be immediately derived from (XXXI.):

$$D = 2nT - z \quad (\text{XXXIV.})$$

The value of  $D$  will be thus made known; and by an obvious transposition of the first equation (XXXII.), the following formula will then obtain:

$$\sin. T' = \frac{1 - \cos. D}{2 \alpha \cdot \sin. D - 2v \cdot \sin. z + \frac{\cos. z - \cos. D}{\sin. T'}}$$

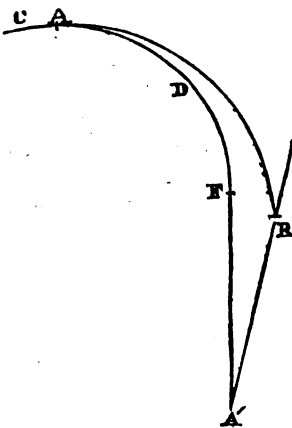

(XXXV.)

Having computed the value of  $T'$ , the quantity  $m$ , which denotes the number of

chains contained in the new curve, will be made known by the formula,  $m = \frac{D}{2T'}$ .

This will, however, be accurately true, only when  $m$  is an integer number, for reasons already explained in art. 5; but the formula (XXXV.) is, nevertheless, obviously rigorous. When the formula  $\frac{D}{2T'}$  does not express an integer number, it will be, most generally, convenient in practice to take for the value of  $m$  the nearest integer number

greater than  $\frac{D}{2T'}$ ; and then, after tracing every chain in the new curve *except the last*, let that last chain be laid from a modulus of curvature expressed by the formula,  $\frac{1}{2} D - T' \times m - 1$ ; which will restore the proper direction to the new tangent, agreeably to principles evident enough from (IV.), and it will not vary, laterally, any material distance from the required position.

Example. Let CADF be a curve whose modulus of curvature is  $1^\circ 30'$ ; and let A be a station in that curve, 25 chains from the extreme station F. From F, suppose a tangent FA' to be laid 30 chains to a point A'. It is then proposed to determine the necessary change of curvature at the station A, in order to trace a new curve AR, such as to pass into a new proposed tangent RA', intersecting the former at the point A', and whose inclination to the common tangent at the station A, exceeds that of the tangent FA, by  $4^\circ 46'$ .

Here,  $T = 1^\circ 30'$ ,  $n = 25$ ,  $v = 30$ ,  $\alpha = 0$ , and  $z = -4^\circ 46'$ ; therefore by (XXXIV.),  $D = 2nT - z = 75^\circ + 4^\circ 46' = 79^\circ 46'$ . Hence, by (XXXV.),  $\sin. T' =$

$$\frac{1 - \cos. D}{2 \alpha \cdot \sin. D - 2v \cdot \sin. z + \frac{\cos. z - \cos. D}{\sin. T'}}$$

$$= \frac{1 - \cos. 79^\circ 46'}{2 \cdot 0 \cdot \sin. 79^\circ 46' - 2 \cdot 30 \cdot \sin. -4^\circ 46' + \frac{\cos. -4^\circ 46' - \cos. 79^\circ 46'}{\sin. 1^\circ 30'}}$$

$$= \frac{1 - .17766}{-60 \times .08310 + \frac{.99654 - .17766}{.02618}}$$

$$= \frac{.82234}{-4.986 + 31.278} = \frac{.82234}{26.292} = .03127$$

$T' = 1^\circ 18'$  = modulus of curvature necessary to trace the required curve AR, agreeably to the principles explained in art. 9. Now, in this instance,  $\frac{D}{2T'} = \frac{79^\circ 46'}{2^\circ 36'} = 29.86$ ; which is not an integer number, and the new curve AR must therefore be made to consist of 31 chains, of which the first 30 will be laid agreeably to the modulus of curvature,  $1^\circ 18'$ . And then,  $\frac{1}{2} D - T' \times m - 1 = 39^\circ 53' - 1^\circ 18' \times 31 - 1 = 39^\circ 53' - 39^\circ 0' = 0^\circ 53'$  = necessary modulus of curvature for the 31st chain.

A laughable incident occurred on the Paterson Railroad on Monday last. While crossing the long causeway, the passengers in the two cars, were startled by loud shouting from the top of the vehi-

cles. Heads were instantly protruded from all the openings, when it was discovered that the passenger cars had been detached from the locomotive and baggage cars, by the breaking of the iron pin with which they had been secured together. The locomotive proceeded nearly three quarters of a mile, before the engineer discovered that he had left his freight in the lurch. So great was the impetus, that the cars did not stop till they had come up with the locomotive.—[Jersey City Gazette.]

[From the Philadelphia Commercial Herald.]

NEW RAILROADS.—The following Railroads are now in progress, or shortly will be, in this State, viz:

1. Lancaster, Middletown, and Harrisburg railroad.
2. Marietta Branch railway, forming a connection with the Columbia and Philadelphia railway, at the depot near Columbia.
5. Strasburg Branch Railroad, extending from Strasburg, in Lancaster county, to the Columbia and Philadelphia railroad.
4. York and Wrightsville Railroad. When this road is completed, there will be a continuous line connecting the city of Washington, through Baltimore, York, Wrightsville, Columbia and Lancaster, with the city of Philadelphia.
5. Cumberland Valley Railroad. When this road is completed, there will be a continuous railway from Chambersburg to Philadelphia via Shippenburg, Carlisle, Harrisburg, Middletown and Lancaster.
6. Wilmington and Susquehanna Railroad.
7. Williamsport and Elmira Railroad, from Williamsport, Lycoming county, to Elmira, in New York 74 miles, to intersect with the New York and Erie railroad.
8. Oxford Railroad, from the Philadelphia and Columbia Railroad, near Coatesville, to Port Deposit on the Susquehanna, thirty-one and a quarter miles.
9. Little Schuylkill and Susquehanna Railroad, from Pottsville and Danville Railroad to the Susquehanna at Catawissa.
10. Lyken's Valley Railroad, from the Susquehanna, near Millersburg, 26 miles above Harrisburg, to the anthracite coal region, 16 miles east.
11. The Valley Railroad from Norristown, to intersect with the Philadelphia Columbia Railroad about 28 miles west of Philadelphia.
12. The Allentown Railroad, from Allentown, Lehigh county, to Norristown.
13. Philadelphia and Norristown Railroad.
14. Philadelphia and Reading Railroad.
15. West Philadelphia Railroad—a branch of the Philadelphia and Columbia Railroad, to enter the city near Market street bridge, 8 or 9 miles in length.

The Cleveland (Ohio) Daily Herald mentions the arrival at that port of the steamboat Thomas Jefferson, with two hundred passengers, on an excursion to the upper lakes.

The same paper says—"Last evening, there were about twenty vessels, sloops and schooners, lying in our harbor. The schr. Henry Norton, Capt. Oliver, 150 tons burthen, cleared for Buffalo, on Saturday evening, from the warehouse of Messrs Kelly & Co. having on board besides a quantity of hams, sixteen hundred bushels of wheat, and one thousand barrels of flour."

Liverpool and Manchester Railroad stock sold on the 13th May at 193d. per share for the 100d.

**CANAL TOLLS.**—There has been received for tolls on the state canals during the months of April and May, the sum of \$353,734.67, viz:  
For 16 days in April, \$150,075.01  
For 31 days in May, 223,659.66

\$353,734.67

This is \$22,985.85 more than was collected for the same months in 1833, when the tolls on merchandise were 25 per cent. higher than at present: And it exceeds the collections for April and May, 1834, by the sum of \$53,048.59.—[Argus.]

[From the Apprentice's Companion.]

MR. BURDEN AGAIN.

Among all the classes of people who constitute the human family, there is no other class who are so useful to the whole, and so poorly paid for it—who are so completely the sport of fortune's unfeeling frolics—so often dieted on hope, to increase the bitterness of disappointment—as the inventors of useful improvements. To a person who is capable of duly appreciating the services of those people, it is therefore peculiarly pleasing to meet with one of them who is proof against the game which fortune would otherwise play upon him, who will not submit, like a silkworm, to spin his cocoon for the benefit of posterity, and die in obscurity, or be scalded to death, but who, when sunk into the yawning gulf of disappointment, will rise triumphant upon the next billow, and laugh at the effects of fate to depress him.

Such were my feelings on being shown a number of horse shoes said to be made by the above named gentleman, by the help of a machine which he had invented. The shoes were very perfect, and I was told his machine would produce forty a minute. I had watched that gentleman's operations with no small interest as an unobserved spectator, while he was rapidly acquiring property by his machinery for making spikes. When, by means of his own mental and bodily exertions, and with his own money, he engaged in his plan of a steamboat, I had strong hopes of his success, but they were not unmingled with fears. But when those fears were nearly dispelled by his prospect of success, when fortune appeared to have acknowledged his demand, and to be actually loosening her purse-strings to reward him,—at that exquisite moment, when his hopes were changing to exultation, but when at one rude crash his labors and his hopes were sunk together, and no visible object intervened to save him from despair and oblivion, I can truly say, that my feelings were more excited than they had ever been by any circumstance in which I had no interest, not even then of a friendly personal acquaintance.

No person will wonder then that when I saw the horse shoes, and learnt their history, I felt a strong desire to see their birth-place, and examine for myself not only the truth of what had been told me, but the *modus operandi* by which the effect was produced.

Accordingly I visited the place a few days since, and though I presented no credentials, I found no want of kind civility, and the result paid me most amply for time and travel. The machine was not yet completed, and consequently not in operation. The shoe in the process goes through three distinct operations, but following in as quick succession as the eye can trace. The first operation requires about twice the time of the others, and is of course to have a duplicate of that part of the apparatus to make it keep pace with the other two parts, and lose no time. It is at present merely set up for trial, and attached to the power of the water-wheel which drives the spike ma-

chinery, and which has no power to spare. A wheel to propel the horse shoe apparatus will be completed in a few days, and in four weeks the establishment will be in full operation. A bar of iron was heated and put in to show me the operation, which whole bar was converted into horse shoes in a little more than one second each. The last shoe came out apparently as hot as the bar went in, and when the part which is to double the first operation is completed, it will make at least 80 shoes per minute. And yet every part of the machine appears to be almost as simple, and quite as little liable to disorder, as a common grindstone; and what appears quite remarkable, it is only a different modification of the machine he has long had in use in making spikes.

If we allow one man to every eight persons in the United States, and one half of these to have a horse shoe, there would be 875,000 horses, which is probably far within the truth. To shoe these horses all round, twice a year, would require 7,000,000 shoes. Allowing his machine to make 80 shoes a minute, and to work ten hours in a day, and 300 days a year, one machine would make 14,400,000 shoes in a year. A small sized shop would be sufficient to contain the machine and necessary workmen, and a small water power would propel it; so that one machine would make the shoes for the above number of horses, and have half the time to make repairs.

The shoes I have examined weigh  $1\frac{1}{2}$  lbs. each, and 7,000,000 shoes would weigh 3906 $\frac{1}{2}$  tons, so that he would have to send from his shop on an average rising of 13 tons daily, which shoes, at one cent per pound profit, would amount to 87,500 dollars a year. There are very few horses which are not shod more than twice a year; and no man can live by making horse shoes, and finding his shop, tools, and coal, at two cents a pound. I see nothing to hinder Mr. B. from realizing the amount here calculated, and I should rejoice to see it doubled.

He has still some prospects with respect to his boat, and he is engaged in a series of experiments to decide the point which has so long and so completely baffled all calculation—the quantity of friction produced by smooth surfaces passing through water; and the plan he adopts to effect it is, I should say, infinitely more demonstrative than any other I have seen.

He who would not wish success to such a man, I would not choose for a neighbor.

ARCHIMEDES.

#### NATURAL SCIENCE IN COMMON SCHOOLS.

*Essay on the Introduction of the Natural Sciences into Common Schools. Read at the Meeting of the American Lyceum, in May, 1833. By Professor Dewey, of Pittsfield.*

As the subject of the following Essay was expressed in general terms by the Executive Committee of the Lyceum, the writer felt himself authorized to discourse upon it in the various aspects in which it presented itself to his mind. He may have entered more fully into the examination of the subject than the Committee expected; and he may have failed to treat upon some part of the subject which they had contemplated. As it is, the essay is presented before them. The thoughts will be arranged under several distinct heads.

I. Object and General View of the Natural Sciences.

The design of Natural History is the description of all the natural productions to which man has access. Its subjects are as numerous and diversified as are the objects

in the atmosphere, in the waters, and on and within the earth itself. The science carries the student into an examination of this extensive department of the works of the Divine Being.

A general and particular classification of natural objects is indispensable to the description of them. The first great and general division is into the three kingdoms, *mineral, vegetable, and animal*, which comprehend all the objects belonging to our globe.

The Natural History of the *mineral* kingdom comprehends the great subject of *Mineralogy and Geology*. Mineralogy classifies and describes all the earths, clays, ores, coals, stones, salts, gases, acids, waters, &c., which are natural productions, and which possess one homogeneous nature, or exhibit homogeneous properties. Geology performs the same task with the rocks or masses compounded of the preceding minerals, lying in extensive strata over the globe, and the strata of earth and clay, and examines the general structure and formation of the crust of the earth, and those changes which have taken place in the materials of which the earth is composed.

For the complete description of these objects, the science of *Chemistry* is essential; for no description will approximate completeness, which does not include the knowledge of the *elementary* substances and their properties, of their combinations and actions, and of the qualities of the compounds. Chemistry, extensive as it is in all its applications, is, in truth, only a subordinate part of the science of Natural History.

*Geography*, also, so far as it is a description of natural objects and exhibits the character of the surface of the earth, its rocks, mountains, volcanoes, petrifications, waters, earths, soils, productions, native or cultivated, is entirely subservient to the great object of Natural History.

Thus far the naturalist contemplates only matter destitute of organization, and operated upon by those unknown and yet well known powers, gravitation, cohesion, and magnetic or electric or chemical agencies. In the other two kingdoms, organized objects are described, exhibiting that well known principle, that mysterious influence, that mode of divine operation, which we familiarly call life.

The *vegetable* kingdom comprehends every plant, as herb, tree, grass, ferns, seaweed, &c., as well as the lichens and fungi, those often minute and shapeless objects, fastened to rocks and trees, or buried in the earth, or just projecting their heads above its surface. Plants cover the earth and rocks, and through the waters, from the equator to the highest latitude yet attained by suffering industry. To him, who has thought of the vegetable world, chiefly in the 'cedar of Lebanon,' or the lofty pine or oak of the forests, or in the general dress of green that decks the country, or in the blushing carnations that adorn our gardens and pastures, or waste their beauty and fragrance on 'the desert air,' the vegetable kingdom is yet an unknown world; and he is a stranger to the delight with which the naturalist searches out the history of a plant too insignificant perhaps to arrest common attention for an instant. All this world of vegetable life and wonder it is the province of the botanist to explore, and to pour into the treasures of Natural History the descriptions of the riches he has procured from these varied and wonderful works of the great Creator.

*Botany* describes and arranges the whole

kingdom of plants. The method, whether on what is technically called the *artificial*, or the *natural system*, is admirable. A great general division of plants is first made, comprising, in one body, those whose organs, employed in the production of fruit or seed, are *visible*, and in the other body, those whose like organs are wholly invisible, or seen only by high magnifying power. The latter division of plants, of which there is a vast multitude, but which present few attractions to most minds, may be passed with only this general consideration; while the former division, which contains the common, and most useful, and ornamental plants, is open to the examination of any mind. The division of plants into *Classes, Orders, Genera, and Species*, or into *Natural Families and Orders*, renders the prosecution of any part of Botany a matter of comparative ease. Connected, as this may be, with the facts of their *economical use*, as food for man or beast, as employed in the great variety of arts and manufactures, as medicine, or as mere ornament, and thus supporting rational life, or promoting the convenience and restoring the health of man, or of multiplying the sources of rational enjoyment, and of developing more perfectly the powers and beauty of the human frame, even a partial knowledge of the vegetable kingdom must be deeply interesting to all who can acquire it.

The animal kingdom is the last and highest of the three grand divisions of natural objects. The organization is more complex and wonderful, and the life itself of higher character. Although it has not been thought easy, in every instance, to point out the difference between a vegetable and an animal, it will be sufficient to consider *voluntary motion* as the characteristic of the animal kingdom. Even in the lowest grade of shell-fish, confined to a rock, we see indications of the same *voluntary power*.

Zoology is the arrangement and description of animals. The divisions are very logical, and the system very complete. If we consider it only in relation to beasts, birds, fishes, &c., a selection of objects of knowledge is very easy.

To excite our attention, however, to the multitude of objects in the animal kingdom, I shall merely mention some of the divisions in zoology: *Crustaceology*, the science of shell-fish, as crabs, lobsters, centipedes; *Conchology*, of shells, as the clam, oyster, snail, &c.; *Entomology*, of insects properly so called, bugs, flies, bees, &c.; *Herpetology*, of oviparous quadrupeds, crocodiles, turtles, lizards, frogs, &c.; *Ophiology*, of snakes and serpents; *Ichthyology*, of fishes; *Cetology*, of whales, dolphins, &c., which produce their young alive, and support them by milk; *Ornithology*, of birds; *Mazology*, of quadrupeds producing living young and suckling them.

II. Reasons for the preceding general view.

I have considered the objects of Natural History thus particularly for several reasons.

1. That the magnitude of the subject, in all its parts, may come up before us, and convince us that only a small part of it can be introduced into common schools.

2. That our attention may be directed to those portions of it which are the most accessible, and have most facilities already prepared.

3. To show the Lyceum that it is not without some plausibility, that many a zealous cultivator of some branch of Natur-

al History considers the project of introducing this study into common schools as little less than a satire upon wisdom, and a burlesque upon knowledge. The finest minds have employed the leisure hours of their lives, and others of most splendid talents have consumed all their days upon the study of only a small part of Natural History, and before them rises, not the mere image, but the living reality of the school-boy, who will not be able to learn more than the rudiments of common education, engaged in this vast study. The prospect is sickening to their souls.

I hope, however, to show that the magnitude and difficulty in attaining a knowledge of it is not opposed to the accomplishment of all that is intended in the common schools. The full and scientific study of the subject would be absurd.

4. That he is a public benefactor, who leads the minds of youth to any interesting knowledge of any of the multiplied works of the Creator, or surrounds them with facilities for becoming better acquainted with these works. The honor now resting upon many who have labored in this cause, will continue to reward those who shall labor for the same great object.

III. Selection of Subjects in Natural Science.

Those parts of Natural History generally considered most appropriate to common schools are Mineralogy and Geology, Botany, and some portion of Zoology. Only parts of these can be made use of.

In *Mineralogy*, the names and general properties of the minerals about a town or district, so as to be readily recognized, might be easily acquired; and in *Geology*, the knowledge of the rocks and strata of rocks or earth, wherever any were visible: also, the general uses of these substances in the arts. This has already been proved by experiment in several schools in Massachusetts; and minerals have been sent to other schools, by way of exchange.

In *Chemistry*, a large number of experiments of the simpler kind might be performed by means of simple and common articles. A little expense would enable a teacher to exhibit some of the gases, and some of the more striking experiments. I have known boys of ten years of age, in my school, form the illuminating gas by a means of a tobacco pipe and some oily seed, as that of the butternut or sunflower, cemented in the bowl by clay, and have seen them delighted with the bright flame produced by its combustion at the end of the stem.

In *Botany*, the parts of plants employed in the descriptions, as the several parts of the flowers and leaves, and the arrangement of plants, as well as the names of many genera and species, might be learned. I knew a lad of eleven years, who, by collecting plants with a botanist two summers, learned the names of four hundred species, and was able to distinguish many more, whose names were not familiar to him, as well as to analyze flowers to a considerable extent.

In *Zoology*, some of the parts of Entomology would be most easy, as insects are so abundant, and many of their changes are so easily detected; of *Herpetology*, in relation to tortoises, lizards, &c.; of *Conchology*, in respect to land and fresh water shells in the country, and collection of shells along the shores of the ocean. Of birds and quadrupeds, the means of knowledge are increasing continually. The collection of specimens would be a healthy exercise, and exert a favorable influence over body

and mind, while curiosity would be excited and gratified.

IV. Advantages of Natural Science in Education.

Besides the value of the knowledge itself, there are indirect advantages attending the study of Natural History, some of which I shall briefly state.

1. This study calls into efficient action the power of discrimination. The constant tendency of the mind is to consider things in the mass. Particularly requires attention, care, direct effort of the mind. Not a step can be taken in Natural History without discrimination. We must begin with particulars, and we must go on with particulars. And we must often begin with a very small part of one particular thing. The mind is trained to minuteness of examination, and to the improvement of its power of seeing and making distinctions. Thence the mind proceeds to generalization. The inductive philosophy is the glory of modern times. It begins with particulars, and ascends to general conclusions.

2. The relation of one part to another of an object must be observed. The process of examination is fitted to induce the habit of attending to the relations of things, and of creating the power to consider the relations of things in all cases.

3. It leads to the adoption of system, arrangement, method, classification. Consider the multitude of facts in Chemistry, insulated and independent, until they were reduced to systematic order by some of the master spirits of modern times. In Botany, the wonderful genius of Linnæ brought into order the heterogeneous mass of its materials. This system, order, arrangement, is now a part of the subject itself, and the study cannot be prosecuted without this part of logic being practically enforced upon the mind.

4. It awakens curiosity and opens the eyes to look with interest upon the works of God. It rouses the faculties from that listlessness, to which there is so strong a tendency in the naturally indolent state of mankind, and yields to the mind that gratification so desirable to be obtained from the very exercise of the powers.

5. It stores the mind with objects of thought and interest, and prepares it to increase their number. These objects, too, can attend us in all our excursions. The naturalist is ever surrounded with those objects which have roused a deep interest in his mind. Cicero's splendid panegyric on Literature is equally applicable to Natural History.

6. Though many of the subjects have less apparent contrivance, and design, and adaptation, than some others, yet these become more evident, as the knowledge is increased, and are finally seen on every side. The mind becomes more familiar with the works of the great Architect, and perceives more of the benevolence and wisdom of our heavenly Parent, if the study is conducted in the proper manner.

Hence these studies exert a peculiar influence on the character of the young. The curiosity excited, and the objects presented continually on every side, offering employment for the mind, and exercise for the body, might naturally lead to important intellectual and moral results. I am aware that this advantage is not the most obvious, and I shall only confirm its truth by a mere allusion to several instances of young men, who have, by an attention to Natural Science, been arrested in their mad career to intellectual and moral ruin. Some of these cases are known also to some members of the Lyceum.

Some part of these indirect advantages must attend any considerable attention to this study, and be enjoyed in no small degree by the young.

#### AGRICULTURE, &c.

[From Transactions of the Essex Agricultural Society.]  
ON COLORING.

The art of fixing on cloths beautiful colors, although not one of the most necessary, has been made by the fashions, taste, and pride of men, in all ages and nations, one of the most valued of inventions. It is altogether a chemical art. Its theory is now well understood, and is in a high degree interesting to every studious mind, useful to all engaged in manufacturing, or in buying, selling, or consuming colored fabrics. It is, therefore, worthy the attention of all our readers.

Colors, to be permanent, must be combined with the fibres of the silk, wool, cotton, or linen, of which the cloth is composed. To understand how this can be effected, we must acquaint ourselves with the laws of chemical affinity. Affinity is nothing more than the disposition or tendency which two or more substances have to unite and form a new compound, differing greatly in some of its qualities from the simple substances of which it is composed; one substance is therefore said to have an affinity for another when, on being brought in contact, it unites with and assumes new appearances and qualities. For example, if iron and sulphuric acid (oil of vitriol) be brought together, they gradually unite and form sulphate of iron (green vitriol or copperas), but the sulphuric acid has a stronger affinity for lime than it has for iron; if, therefore, lime be brought into contact with sulphate of iron, the sulphuric acid quits the iron, seizes on the lime, and forms sulphate of lime (plaster of Paris.) Substances used in dyeing possess an affinity for the fibres of the cloth, and when dissolved in water or some other liquid, and brought into contact, they unite, and change either the color of the fibres, or so change their qualities, as to dispose them to unite with other coloring matter for which before they had no affinity.

The art of dyeing, then, consists in combining a certain coloring matter with the fibres of the cloth. This process cannot be well performed unless the dye-stuff be dissolved in some liquid, and the particles so separated that their attraction for each other becomes weaker than the attraction for them exerted by the cloth. When the cloth is dipped into this solution, it attracts the coloring matter, and from its stronger affinity takes it from the solvent and fixes it upon itself. The facility with which cloth imbibes a dye, depends on two circumstances, namely, the affinity between the cloth and the dye-stuff, and the affinity between the dye-stuff and its solvent. It is of importance to preserve a due proportion between these two affinities, as upon that proportion much of the accuracy of dyeing depends. If the affinity between the coloring matter and the cloth be too great, compared with the affinity between the coloring matter and the solvent, the cloth will take the dye too rapidly, and it will be scarcely possible to prevent its color from being unequal. On the other hand, if the affinity between the coloring matter and the solvent be too great, compared with that between the coloring matter and the cloth, it will either not take the color at all, or take it very faintly. Wool has the strongest affinity for most coloring matter, silk the next

strongest, cotton a much weaker affinity, and linen the weakest of all. In order, therefore, to dye cotton or linen, the dye-stuff should, in many cases, be dissolved in a liquid for which it has a weaker affinity than for the solvent employed in dyeing wool or silk. Thus we may use iron dissolved in sulphuric acid to dye wool, but for cotton and linen it is better dissolved in vinegar. Was it possible to obtain a sufficient variety of coloring matters having a strong affinity for cloth, the art of dyeing would be exceedingly simple and easy. But this is by no means the case; if we except indigo, the dyer is scarcely possessed of a dye-stuff which yields of itself a good color, sufficiently permanent to deserve the name of a dye. To obviate this difficulty, some substance must be employed which has a strong affinity both for the cloth and the coloring matter. Substances employed for this purpose are called mordants. Those chiefly used are earth, or metals, in the form of salts or in solution, tan, and oil. One of the most frequently used is *alum*. This salt is composed of pure clay (alumina) dissolved in sulphuric acid. Into a solution of alum the cloth is dipped, the fibre of the cloth having a stronger affinity for the clay than the sulphuric acid has, unites permanently with it. It is then taken out, washed and dried, and will be found a good deal heavier than before, although the color remains the same, the clay, which now forms a part of it, being perfectly white. The cloth may now be dyed by dipping it in a solution of any coloring matter for which the clay has a strong affinity. The clay and coloring matter may be united previous to the immersion of the cloth, and the fibres will still unite themselves with the compound, but not so equally and permanently as when dipped into each of the solutions separately. But the sulphuric acid has rather too strong an affinity for the clay to yield it readily even to wool. Most dyers, therefore, add to the solution of alum a quantity of tartar. Tartar is composed of potash and an acid found in grapes and some other vegetables, called tartaric acid. When solutions of alum and tartar are mixed, the sulphuric acid quits the clay and seizes on the potash, dislodging at the same time the tartaric acid, which seizes in turn on the clay just abandoned by the sulphuric acid. The tartaric acid, having a weaker affinity for the clay than the sulphuric acid possesses, yields it more readily to the cloth. Another purpose is also gained: the sulphuric acid remains combined with the potash, and this corrosive substance is thereby prevented from injuring the texture of the cloth. For cotton and linen, which have a weaker affinity to clay than wool or silk, another process becomes necessary. Lead or lime dissolved in acetic acid (vinegar) is poured into the solution of alum. A solution of sugar of lead is frequently used. The sulphuric acid quits the clay and seizes on the lead or lime, both of which, united with this acid, form insoluble powders, which fall to the bottom, and the acetic acid unites with the clay, for which it possesses only a weak affinity, and readily yields it to the cotton or linen immersed in it.

Metallic salts may also be used as mordants. Those of iron and tin are extensively used in dyeing. Iron is used as a mordant in two states, in that of sulphate of iron, (copperas,) or acetate of iron, that is, iron dissolved in vinegar or in the acid obtained by distilling wood (pyrolygneous acid.)

Tin is used as a mordant in three states—dissolved in nitro-muriatic acid, (a mixture of the acids obtained from saltpetre and

from common salt,) in acetic acid, and in a mixture of sulphuric and muriatic acids. The nitro-muriate of tin is the common mordant employed by dyers. It is prepared in the following manner: Melt black tin and pour it into water briskly agitated with a bundle of small rods, take of this granulated tin 2 oz., nitric acid 1 lb., water  $\frac{1}{2}$  lb., common salt or sal ammoniac 2 oz., mix them together in a glass vessel, and the tin will be slowly dissolved.\* When nitro-muriate of tin is to be used as a mordant, it is dissolved in a large quantity of water, and the cloth is dipped in the solution until sufficiently saturated. It is then taken out, washed, and dried. Tartar is usually dissolved in the water along with the nitro-muriate of tin. This changes the compound into a solution of the tartrate of tin and nitro-muriate of potash. The tartrate of tin is again decomposed by the cloth. The metal quits the acid and attaches itself to the fibres of the cloth, and in this state possesses a strong affinity for coloring matters, and forms with them the most permanent and brilliant dyes.

Tan is also employed, along with other mordants. It is found in nutgalls, oak and hemlock barks, sumach, and in a great variety of other vegetables. It is that part of barks, &c. which has a strong affinity for glue, of which hides are chiefly composed, unites with it and forms leather. It has a strong affinity also for cloth and for several coloring matters. Silk is capable of absorbing a very great proportion of tan, and thereby acquires a great increase of weight. For this purpose alone it is sometimes employed by silk manufactures. Tan is often employed, also, along with other mordants, in order to produce a compound mordant. Oil is also used for the same purpose, in dyeing cotton and linen.

Besides these mordants there are several other substances frequently used as auxiliaries, either to facilitate the combination of the mordant with the cloth, or to alter the shade of color; the chief of these are tartar, sugar of lead, common salt, sal ammoniac, sulphate of copper, (blue vitriol,) acetate of copper, &c.

Mordants not only render the dye permanent, but have also considerable influence on the color produced. The same coloring matter produces very different dyes, according as the mordant is changed. Cochineal, with salts of iron, produces black,—with the salts of tin, scarlet,—and with alum, crimson. In dyeing, then, it is not only necessary to procure a mordant which has a sufficiently strong affinity for the coloring matter and the cloth, and a coloring matter which possesses the wished-for color in perfection, but we must procure a mordant and a coloring matter which, when combined together, shall produce the wished for color in perfection.

The colors denominated by dyers simple, because they are the foundation of all their other processes, are four, viz. blue, yellow, red, and black. A few simple directions for dyeing wool, silk and cotton of these colors will now be given. We write for prudent and economical housewives, silk culturists, and agricultural manufacturers, and the means within the reach of such must there-

\* When common salt, which is composed of muriatic acid and soda, or sal ammoniac, composed of the same acid and ammonia, is mixed with diluted nitric acid, a part of the nitric acid seizes on the soda or ammonia, and sets at liberty a part of the muriatic acid, which mixing with the remaining nitric acid, forms nitro-muriatic acid, (aqua regia,) which readily dissolves tin, gold, &c. It is more economical, however, to add sulphuric acid enough to saturate the base of the salt, which sets all the muriatic acid at liberty, and leaves the nitric acid undiminished.

fore be kept continually in view, in all the operations recommended.

**Blue.**—Indigo is the only substance that can be economically used in families for coloring blue. The best or purest indigo is light, easily powdered, tasteless, almost destitute of smell, and breaks smoothly, that is, with smooth surfaces. Some will float on water, and this is generally the purest. The color of indigo also varies. There is the blue, the violet, and copper colored. Although these may all contain nearly the same quantity of coloring matter, yet they are differently valued, the blue selling 20 per cent. higher than the violet, and from 40 to 80 per cent. more than the copper colored. The blue is preferred by dyers for combination, or solution in sulphuric acid, and the copper colored for the indigo vat, in which it is dissolved in a potash ley, aided by bran, madder, or other vegetable products, in a state of fermentation. Before indigo can be applied and fixed upon the fibre of cloth, it must be dissolved in water. But it cannot be dissolved in water in its blue state; it must be converted to a green or yellow color, and then it readily dissolves, is attracted by the fibres of the cloth, becomes permanently combined with them, and on being exposed to the air becomes again blue. In the solution of the indigo, therefore, consists the whole art of coloring blue. The following are among the most easy and simple methods of dissolving indigo, or, in other words, forming a blue dye.

**First Method.**—Take indigo, well powdered, one ounce; quick lime, one ounce; potash, two ounces; copperas, two ounces; molasses, half a pint; warm water, one gallon. Mix, and stir occasionally, keeping the vessel, of copper, iron, or earthen, well covered and in a warm place. The liquor will soon become green, covered with a copper colored or blue scum. In twenty-four hours it will be fit for use. Immerse the stuff to be colored for a longer or shorter time, according to the shade required. The strength of the color may also be varied by using a greater or less quantity of water. A very little practice will enable any one to give wool, silk, or cotton, properly prepared, with this dye, a beautiful and permanent blue, of any shade they may choose.

**Second Method — Saxon Blue.**—In this method, the indigo is dissolved by the aid of sulphuric acid, without losing its blue color, but it undergoes a change which renders it less permanent, and is therefore not much used, except for articles not very durable, or when a deep, unfading tint is not considered of much importance. This preparation is kept in the shops, under the name of *Liquid Blue*, or *Chemical Blue*, and is much used for blueing white cotton and linen garments, from which it is readily washed out, even in cold water. It is also extensively used in coloring greens, giving, with yellow, a more brilliant color than the blue obtained by the first method. On wool and silk it is much more durable than on cotton, and on articles which do not require frequent washing, may be often used advantageously as a blue dye. It is prepared as follows:

Take indigo, well powdered, one ounce; sulphuric acid, four ounces — mix it in a glass or stone ware vessel, and let it stand twenty-four hours, stirring it occasionally — then add one ounce of dried potash. Let it stand twenty-four hours longer, add half a pint of water, and bottle it up for use.

Mix a wine glass full of this liquid in a pail full of boiling water, and dip the stuffs till they acquire the color desired. More

of the liquid must be added when the water becomes nearly clear, before the stuffs have acquired a color sufficiently deep.

**Yellow.**—There are a great number of imported and native plants, roots and barks, that, by the aid of the mordants alum and tin, dye yellow. But the very best of all these, viz. the yellow oak bark, or quercitron bark, as it has been named in England, being very plenty in this country, it seems altogether unnecessary even to mention any other.

To dye 10 lbs. weight of cloth, or woolen stuffs, of the highest and most beautiful orange yellow, 1 lb. of quercitron bark, and the same weight of murio-sulphate of tin, will be required\*; the bark, powdered and tied up in a bag of thin cotton or linen cloth, may be first put into the dyeing vessel, which of course must be brass, copper, glass or earthen, with hot water, for the space of six or eight minutes; then the murio-sulphate of tin may be added, and the mixture well stirred two or three minutes. The cloth, previously wet thoroughly with warm water, may be put in and turned briskly a few minutes; the color applies itself in this way so equally to the cloth, and so quickly, that after the liquor begins to boil, the highest yellow may be produced in less than fifteen minutes, without any danger of its proving uneven.\*

\* Murio-sulphate of tin. This preparation differs somewhat from the muriate of tin, or nitro-muriate of tin, the method of preparing which is given in a preceding part of this essay. It is prepared as follows: Take six ounces of muriatic acid, and pour it upon about the same weight of tin, granulated as above directed, in a glass vessel. Then pour slowly upon the same four ounces of sulphuric acid, and let it stand in a warm place till the acids saturate themselves with tin, that is, till they will dissolve no more, which will be soon effected, if heat be applied, and gradually without being heated.

\* Should a deeper orange tint be desirable, add to the quercitron bark a little madder, perhaps an ounce or less to the pound of bark, according to the color desired. This will greatly increase the beauty of the color, when examined by candle-light.

OF RAISING CEDARS FROM THE SEED, AND TRANSPLANTING THEM FOR HEDGES. —We annex below the extract referred to by our correspondent, and thank him for pointing out what we had forgotten, and still more for adding thereto his own experience on the subject.

Fayetteville N. C., Feb. 16, 1835.

To the Editor of the Farmers' Register.

Mr. S. Hobson will find in page 22, Vol. III. of the American Farmer, the mode of raising cedar hedges from the seed. I have followed the directions given there with the most satisfactory results. More than half the cedar berries prepared and planted agreeably to those instructions vegetated and flourished well.

I have not lost more than one tree in 50 by transplanting, unless the tops were cut off. In that case the trees die or decline, so as to be of little account: they will improve by severe trimming if the top is left perfect. I prefer a wet season in March or April for transplanting ever-greens, but have succeeded by taking proper pains at all seasons, except the extremes of heat and cold.

B. R.

[From the American Farmer.]

Gather the berries in November or December. Rub off the skin and wash the kernels—rubbing them well between the hands, so as to get off as much of the resinous substance as possible, then mix them with unslacked ashes, and let them

remain in the ashes for a fortnight; then plant them in drills as you would peas, and they will vegetate and come up the following spring; and being well nursed, they will in two years be fit to plant out in hedges. About the first of March is the proper time for planting them—throw into the bottom of the trench, light rich earth, such as may be had from the surface of productive ground. When the trees attain three feet high, you should begin to train the hedge—about the middle of summer is a suitable time for this operation, and it ought to be carefully continued until the hedge is as high as you may desire it—about seven feet high, and three and a half feet broad, is sufficient.

N. B. The better you cleanse the kernel, the more certainly the seed will vegetate—by proper care an excellent hedge may be expected in seven years, which for beauty and durability cannot be surpassed, either by thorns or any other growth.

**Broom Corn.** By H. C. [For the New York Farmer and American Gardener's Magazine.]

The cultivation of Broom Corn is carried on to a very great extent on some of the alluvial lands on the Connecticut river, and in small patches in many of the interior towns. The towns of Hadley and Hatfield raise large quantities, which are manufactured into brooms, and distributed throughout the country. The seed is considered of about two-thirds of the value of oats, and, mixed with corn, makes an excellent provender for the fattening either of swine or neat cattle. The return of seed is somewhat precarious; but often it is abundant, and will more than pay the whole expense of cultivation and preparing the crop for the market. I have known a case in which 150 bushels of good seed have been obtained from an acre; and I have been assured, on good authority, of a still larger yield, though this is not frequently to be expected. One thousand pounds of broom to an acre is a very good crop. It will pay well for manuring and good culture. No crop is more beautiful than the standing corn when in perfection. It frequently attains a height of 12 to 15 feet. The stalks of the plant are very long and hard, and, therefore, rather difficult to load upon a cart. They are considered as of no value but for manure. The usual practice is to table the corn, that is, to cut off the top, or tassel the broom, as it is called, about two feet from the top, and bending the stalks of two rows together, lay it down until it is seasoned and fit to be carried in. The remainder of the stalks are then burnt in the spring in the field, and some little advantage is derived from the ashes. A much better way, it is thought, is, after gathering the crop, to cut the stalks and lay them lengthwise in the rows, and plough them immediately under. They will become entirely decomposed by spring. A still better mode is to carry them into the cattle and sheep yards, where they become incorporated with the manure, and make a valuable addition to the compost heap.

The seed is planted in rows, wide enough apart for the plough to pass conveniently between them, and dropped in hills about

eighteen inches from each other. Four or five stalks are considered sufficient to remain in a hill—there are sometimes allowed. The cultivation and manuring is more than for Indian corn. It may be manured in the hill or by spreading, or in both ways, as you have the means of high cultivation, which this plant will bear. The stalks are not eaten by cattle, nor even browsed by them; but I am not certain that the leaves would not furnish a good feed for young stock, if stripped early, when tender, and well cured, as the Indian corn blades are cured at the south. What would be the effect of such mutilation upon the crop itself, and whether it would compensate for the labor, are inquiries which I am not able to answer, and in respect to which I cannot learn that any experiments have been made. It is an important subject for experiment. As it is at present managed, the plant returns little to the ground compared with Indian corn; and the Hadley and Hatfield farmers are obliged to connect with it the fattening of beef to a considerable extent, to furnish manure for their broom corn.

It is deemed a good crop when the broom commands five cents per lb. The price has heretofore been subject to great fluctuations. At one time it was the custom for every farmer to make up his own brooms, and then to go and sell them where he could. This was bad for all parties. It brought too many competitors into the market; and often unduly depressed the price, and the buyers were often obliged to put up with an inferior article. Now the manufacturing and the growing of the broom are in different hands; and the farmer, as soon as his broom is ready for the market, finds a purchaser at a steady price; and the manufacturer feels that his reputation, and consequently his success, are concerned in the quality of the article which he furnishes.

It is a little remarkable, that notwithstanding the extent and importance of this product, for one manufacturer within a few miles of me makes several hundred thousands of brooms a year, that in no book of agriculture in my possession can I find any account of the cultivation of this plant, not even in that excellent New-England work, "The Complete Farmer." The Shakers for a long time almost monopolized the raising of the plant and the manufacture of brooms; and their brooms, which, like the other manufactures of this industrious community, were always of a superior quality, usually commanded a high price, generally 42 cents or more. Corn brooms are now frequently sold from eight to twenty-five cents; but many of them are like Pindar's razors, "made to sell." The Shakers, however, maintain the quality of their manufacture. The handles, in an unfinished state, are furnished for a cent a piece; the wiring and the tying on are usually done by the hundred. The scraping the seed from the brush is an unpleasant business, and often very injurious to the eyes. The manufacture, where it has been carried on extensively and with ample capital, has yielded encouraging profits.

An intelligent and enterprising farmer in my neighborhood, who last year cultivated three acres and one half of broom corn

in our alluvial meadows, has been kind enough to furnish me a detailed account of the expense of cultivating an acre, which may be relied on for its exactness, but in which the rate of labor is probably over-estimated by the day. His broom was sold in the autumn at eight and one half cents per lb. It readily commands this spring 12½ cents; had he fortunately retained his broom until this time, the profits would have been greatly enhanced, while the expenses would, of course, have remained the same.

Account of the expenses of cultivating an acre of Broom Corn in Deerfield meadows, in the year 1834, by Mr. Alvah Hawkes:

One ploughing, 12th May,	\$1.25
Holeing out, one third of a day's work,	34
Ten loads of manure, at 75 cents,	7.50
Putting manure in the hill,	2.00
Planting, one day's work,	1.00
Seed, 4 quarts, at 75 cents per bushel,	10
Hoeing, first time 3 1-2 days,	3.50
do 2d do 3 do	3.00
do 3d do 2 1-2 do	2.50
Horse and boy to plough for the season,	1.00
Tabling and cutting, 4 days,	4.00
Gathering, carting, and packing away,	2.50
	<b>\$28.68</b>

The expense of cultivating one acre is \$28.68 cents, the labor being rated at one dollar per day, which is more than the actual cost, as I hired my laborers by the month, at from six to ten dollars per month. The yield was at the rate of 991 pounds to the acre. Had all my ground been fully stocked, it would have exceeded ten hundred pounds per acre.

The expense of scraping the brush for the seed was thirty-three cents per hundred pounds. The brush was sold at 8½ cents per pound. The crop of seed was light and poor; fifty bushels to three acres, worth 16 2-3 cents per bushel, or \$8.33 to an acre.

Summary expense of cultivation of one acre as above,	28.68
Scraping 1000 pounds,	3.30
Board of man 5 days,	1.07
Rent of land, say \$16 per acre,	16.00
	<b>49.05</b>
Sale of brush, 1000 lbs. at 8½c.	85.00
Seed upon one acre,	8.33
	<b>93.33</b>

Nett profit on one acre, **\$44.28**

The sale of the brush at 12½ cents per pound, the present price, would have enhanced the profits forty dollars, and made them \$84.28. This is very remarkable, and certainly affords ample encouragement to labor. That it can be often done is not to be expected; and yet there is nothing extraordinary in the process. The uncertainty of the seasons is something, and the fluctuations in the market prices of broom are great. The amount of crop, though large, was not more than can usually be commanded by good and generous cultivation. Many of our lands, besides the alluvial meadows, are capable of producing good crops; and the great yield of 150 bushels of seed to the acre mentioned above,

with broom, of course, in proportion, was produced in one of the most rough and rocky towns in the commonwealth, and on land which owed every thing to good management. I hope the length of these details may be excused. H. C.

Meadowhanks, 7th May, 1835.

**ANTHRACITE ASHES.**—The Philadelphia U. S. Gazette says, "A lot of land, clay and sand, was covered over with ashes from anthracite coal, and clover seed sown upon it in abundance. The clover after waiting a little while longer than usual, sprung up like an ill weed, and about two weeks since presented a luxuriance of growth exceeding any thing of the kind we ever saw. The clover had the appearance of tall pea vines, so rank had it shot up. If anthracite ashes have such virtues, it would be well for the public generally to understand it."

**SHEEP SHEARING AT NANTUCKET.**—This annual festival, and the only holiday celebrated upon the island, takes place on Monday and Tuesday next. The steamboat Telegraph leaves New Bedford for Nantucket on Sunday morning and Monday afternoon.

**THE GRAIN CROPS.**—The subjoined letter is from a respected friend in Jefferson county, Virginia (one of the most productive grain-growing counties in the State). In publishing so unfavorable an account of the crops in that quarter, it seems to be proper to say that the accounts from the Pennsylvania grain districts, and other parts of the country, are altogether more favorable than the following, and promise indeed an average crop. [National Intelligencer.]

Virginia, June 11, 1835.

To the Editors.—Gentlemen: The crop of wheat is actually indifferent, indeed bad—few can reap half a crop, and others not more than a third or a fourth. The rye is generally tolerable. The corn is backward, and by good cultivation and a favorable season will be considerable, there being more than is commonly planted. The oat crop, if favored with rains, will be great, as much more than usual is sowed, to supply the deficiency or failure of the wheat, destroyed more by the fly than by the winter. The certainty of a great scarcity of wheat and rye, should induce merchants to prepare to import grain, otherwise the population of the large cities will greatly suffer. It will be unwise and very imprudent, to trust altogether to the harvest of this year. If this shall be the indisposition of merchants, distress among the poor population of large cities will be extreme. This country will have no grain for exportation, and as the probability is, there will be a deficiency of grain for home consumption, resort should be had to foreign countries that may have to spare. Yours, &c.

[From the Troy Whig.]

**WHEAT CROPS,** in many parts of the country, appear to have been materially injured by the severe winter. In Maryland not more than half a crop will be secured—the wheat being either "frozen out" or "blown out" of the ground, leaving large sections almost entirely bare. In some few instances, the wheat fields had been ploughed up and planted with Indian corn. The latter, it seems, has also suffered greatly from the cut worms; but the Rye is represented as quite promising, and the crops of Clover, Grass, Potatoes, and Fruit, with the exception of peaches, bid fair to be unusually abundant.

The Richmond Enquirer states that the wheat crop in Virginia does not promise one third of the usual harvest. The severe winter has injured it extensively through all the South.

In the western part of the state of New York, Wheat has suffered more from the winter, perhaps than was ever before experienced. The large harvests of Genesee county will be diminished.

In some districts, however, appearances are better. The Pennsylvania papers speak of the prospect of an abundant harvest.

The Cincinnati Post of May 30, says—"The season, which but a few weeks since was very unpromising, now bids fair to be one of the most productive that has been for many years, even the wheat will prove to be at least an average crop."

The Poughkeepsie Eagle of the 28th, says—"The prospect of the approaching wheat crop in this country, is generally good."

NEW-YORK AMERICAN.

JUNE 16-19, 1835

LITERARY NOTICES.

WORKS OF JAMES K. PAULDING, vols. I. and II. Uniform edition. New York, HARPER & BROTHERS.—The two volumes which commence the series carry us back at once to the days of our boyhood—and to the impressions, yet fresh and unaffected, which *Salmagundi*, on its first appearance, made upon young and old of the town:—we have here *Salmagundi* re-published. Mr. Paulding, it is well known, shares with *Washington Irving* in the authorship of these charming papers—which have been revised by both, but most judiciously not altered—"a few of the most glaring errors and flippancies only," as it is modestly said in the preface, having been expunged. To the thousands and tens of thousands of readers of the present day, who only know *Salmagundi* by tradition, the publishers have, in these volumes, rendered an acceptable service. They have, too, given them a very handsome mechanical dress and execution.

THE FAMILY BOOK, OR INSTRUCTIONS CONCERNING THE RELATIONS OF LIFE: 1 vol. New York, D. APPLETON & Co.—Practical religion, as it is called for, and exemplified, in the every day life of those who are truly influenced by its spirit, is the theme of this volume. It is therefore a serious volume, and only to be taken in hand by such as are disposed seriously to inquire into, and abide by, the lessons it inculcates.

The whole story of the Sutton family is well devised, and sustained with skill and consistency.

PENCIL SKETCHES, or Outline of Character and Manners—by MISS LESLIE. Second series. 1 vol.: CARY, LEE & BLANCHARD.—Keen observation, quick perception of the ridiculous, and a quiet humor in the mode of bringing out the characters, recommend these Pencil Sketches—now gathered into a volume, from the different periodicals in which they originally appeared.

WORKS OF MRS. SHERWOOD; vol 10—uniform edition—New York; HARPER & BROTHERS.—In this volume the *Lady of the Manor* is continued; being the second of four volumes, in which this portion of Mrs. Sherwood's works are to be comprised.

REVISTA MEXICANA. Periodico científico y literario No. 1, vol. I. Mexico—1835, p. 100.—This is the commencement of a periodical work, formed somewhat on the plan of the Quarterly of England and America, but embracing also matter, which with us is deemed appropriate to the pages of a Monthly Magazine. It is to be published once in every two months; and, as we are informed in a well written introduction, embraces a large circle of topics for discussion, from which politics are excluded.

A brief notice of the subjects of some of the articles will perhaps furnish the most correct idea of the work. The first article is "upon the capacity of the Indians to form abstract and general ideas," and purports to be a "refutation of Robertson."

In the department of History we find "documents pertaining to the reign of Philip IV.," published for the first time from the original MSS., and a notice of "some of the voyages and maritime discoveries made by the Spanish;" commencing in 1383, and brought down to 1792. This is extracted from *Nicobarre's* collection of voyages and discoveries; and it has occurred to us, that in the department of history, the work may be made one of much interest to the American antiquarian. By the way, the successful application of steam as

the propelling power of boats, would see *Nicobarre*, to have been made as far back year 1543, by one *Blasco de Garay*, who obtained his success in the port of Barcelona, with a boat of 200 tops, in the presence of many.

rewarded by the crown, and a record of the transaction, extracted from the royal archives duly authenticated, is presented by *Nicobarre*.

There is also a very interesting biographical sketch of Dona Beatris de Bovadilla, the companion and heroic friend of Queen Isal was so her earnest, and, according to Piquent entreaties, that the Catholic Queen prevailed on to extend to "the great admirer patronage which resulted in the discovery America.

We have not room for farther remark on our articles. We hope that so fruitful a field the antiquities of Mexico will not be overlooming numbers of the work, and common as we most cheerfully do, this first specimen much interesting matter, presented on excellent paper and in a beautiful type, we shall look with interest for those which are to follow.

THE REPUBLIC OF LETTERS; No. 53. Mr. H. H. Nicholas: New York; GEO. WOOD.—In Wednesday's paper we referred new auspices under which this work was forth to appear, and we now have to acknowledge the first number of the third volume. 7 says of *Elia*, (Charles Lamb,) lead off, give an idea of the cheapness of this production may be stated that the two volumes of the says, will be comprized in three numbers, 18 3-4 cents, of the Republic of Letters. this result produced by employing small type common materials. On the contrary the typed pages are open, clear, and distinct, the paper is white and of excellent quality.

JACOB'S LATIN READER, with notes and instructions, by JOHN D. GUNBY: 5th New York & New-York, W. E. DEAN. In stating the thin school-book, and the fact that it has passed to a fifth edition here, we furnish it and sufficient voucher.

AN ENGLISH GRAMMAR, in which the principles of the language are methodically arranged, practically illustrated, &c. &c., for the schools: by CORNELIUS B. EVEREST: No J. DUNHAM. This is a well printed grammar which adopts the method of instruction of M

ANNALS OF PHRENOLOGY: vol II, No. 1 ton, MARSH, CAPEN & LYON. We have not seen this periodical which must now be of age. It is published under the superintendence of a committee, who are the Rev. John Pierpont W. B. Fiske, and Doctors F. F. Flagg and H. H.

THE HISTORY OF IRELAND: by Thomas I. Esq., vol. I., Philadelphia; CARY LEE & BLANCHARD.—We have, before, in speaking of the volume of a work, that will swell through the volume of a work, that will swell through: we presume, described it, on the faith of extracts we have seen, as full of antiquarian re-written in a style the opposite of that Moore has heretofore adopted, and dry and be in keeping, with the musty records, which have been ransacked for materials. Its history down only to the end of the seventh century; it advances towards our ages, it will also, we not, increase in interest.

THE AMERICAN MONTHLY MAGAZINE for THE KNICKERBOCKER MAGAZINE for JULY THE U. S. NAVAL AND MILITARY MAG for JUNE. HOWARD—Washington.

strongly interested me. It was Malleherbes—the honest and able minister—the undaunted advocate—the kind and true friend of Louis Capet—accompanied by his daughter, the Marchioness Ro-cambo, and her child—he was about to die on the scaffold. But the child! surely they would not murder the child? And why not? The old man's crime was his innocence and purity of character—how then could the child escape? The wagon was drawn up beside the guillotine, and all was soon ready for the first execution. Malleherbes stood nearest the steps, and he was about to descend, when a savage voice cried out, "The child first!" The old man would have remonstrated, but his daughter checked him—"Tis but a moment, my father," said she, 'tis but a moment,"—she raised the child in her arms, and herself handed it to the executioner. The little creature, frightened by the savage looks of the man, screamed out, "Don't leave me, mother—come with me—don't leave me." "I will not leave you, my child—I will be with you in a moment." The child was pacified, and the mother turned towards her aged parent, and buried her face in his neck; he, too, bent forward till his white hair flowed over her shoulders. Thus they saw nothing—yet they were so near they must have heard the jerk of the string, that loosed the ponderous axe—its clatter as it fell. A strong shudder shook the frame of the mother: but when the executioner called out, "Now for the woman," she raised her placid face from her father's neck—looked fondly in his face—kissed his cheek—"For a brief moment, farewell, my father." She stepped with a light firm tread from the wagon—mounted the scaffold—and in a moment she was with her child.

Malleherbes came next; he had summoned all his energies for this last scene in his life's drama, and he played it nobly. Never in the proudest days of his power had the minister looked or moved with a loftier dignity. With a wave of the hand, he repulsed the rude advances of one of the guard, who would have assisted his descent from the wagon. Self-sustained, in body as in mind, he advanced slowly to the scaffold—even the fiends who surrounded it were awed—they shrunk back, and allowed the old man to place himself, almost unassisted, on the platform. They would have bound him, but he gave a forbidding look—it was enough—the executioner retired—the plank was pushed forward—and for a moment the old man must have seen, in the basket below, the heads of his children. This additional pang, if it was one, was short; the executioner jerked the string, and all was over.

We conclude with a short and well-related naval incident—if so a passage on shore may be called:

A few years since, the officers of our frigate, then lying at Mahon, were invited by the Dutch officers to join in the funeral ceremonies of paying the last tribute of respect to one of their departed shipmates. At the appointed hour we assembled on board the Dutch ship, and shortly after took our station in a line of some ten or twelve boats, pulling minute strokes, with colors half-mast. Landing at fort St. Philip, the procession moved in the following order: our band in the van playing a funeral dirge, the Dutch marines, then the coffin, borne by eight men, a division of sixty sailors, followed by the Dutch and American officers and a number of citizens. In this order we commenced our march up to the burying ground with slow and martial tread. It was certainly an imposing scene, and one well calculated to call forth sober and solemn feelings, and reflections of a melancholy cast. When about midway in our passage, a scene took place which the pen, the pencil, or the tongue, is inadequate to describe, changing our gravity to mirth, and upsetting all our gloomy meditations. We came to a sudden halt—the music ceased, and were seen retreating to the rear; the Dutch marines, from the "reverse arms," brought their pieces to the "charge," with fixed bayonets—the swords leaped from the scabbards and glistened in the sun; and with the clattering of instruments, the clashing of arms, and the "war shout" of our party, we received the enemy. He came down upon us, under cover of a cloud of dust, breaking through the troops, capsizing the coffin, trampling some under foot, tossing others in the air, and dispersing the rest of the party; and then halting in his furious charge, turned round, and, with a look of inexpressible amazement, reared aloft his noble head, and died covered with wounds.

The mysterious enemy proved to be as noble a

looking bull as ever nature gave liberty to roam the prairies. He was large, powerfully built, and of perfect symmetry, with a coat of black matted curly hair about his short curved neck and tremendous shoulders—his body smooth and of a glossy black—his horns were short, stout, and well pointed. He was grazing quietly in a field, when his attention was attracted by the music; but the sight of the scarlet uniform of the band soon roused his passion, and he commenced pawing the earth, thrashing his tail, and shaking his head, with evident signs of increasing anger; then he would make one or two fearful bounds, plough up the earth with his horns, and throw himself into a thousand attitudes: at last, as the procession neared him, his rage became ungovernable, and clearing the wall with a graceful leap, he came bounding along the road with his head down, his nostrils distended, his eyes glaring fire, the foam flying from his mouth, bellowing most furiously, with his tail well "peaked up," dashed through our ranks with all the force and gallant bearing of Murat's cavalry—and one might say with equal effect!—I never witnessed a more ludicrous scene, or heard such a burst of laughter as came from our ranks! Oh! how I wished for Hogarth to have sketched that inimitable scene! The subject, "a Quixotic bull routing a military funeral!!" It took some time to get in order again, I mean in regard to position, for our risibles were too highly charged not to render an occasional blow off absolutely necessary: the weight of gravity was too light not to keep the valve close, and when it did start up, there was a bursting forth that convulsed the whole party: how the ceremony was performed, I do not know. I only remember the full vent we gave to our feelings on reaching the ship. OCEANUS.

THE KNICKERBOCKER is, we think, less clever than usual. The papers on American literature, are tedious and querulous. They are, moreover, unjust in the assertion, that public opinion, in this country, as to native writers, waits for the sanction of transatlantic critics. The real complaint is, as we think, that public opinion is sought to be forced into the approval of American writings, merely because they are American. Our authors, and our taste as readers, need much more the repression and improvement of judicious criticism, than the stimulus of the forcing American system.

Of the Furf Register we have left ourselves little room to say more, than that it abundantly sustains its interest for sportsmen.

SKETCHES OF HISTORY, LIFE, AND MANNERS IN THE WEST.—Under this title a new work, in two volumes, by James Hall, is about to appear. It will be published by Harrison Hall, of Philadelphia, and comprise, as we learn from the Prospect—

1. A Treatise on the intercourse between the American people and the Indian Tribes.
2. A Review of the History of French settlements in Upper Louisiana and the North-Western Territory.
3. A History of the Pioneers of the Western States—containing a brief account of the first settlements on the Ohio river, and Sketches of the Habits, Manners, and Institutions of the first settlers.
4. Statistics of the Western States—containing a Topographical Sketch of the country—an extended description of the region of the Prairies—their agricultural advantages, phenomena, &c., with a theory of their origin. Account of the public lands—the mode of sale and regulations of the office—with a review of the various propositions made in Congress for disposing of the public domain. Steamboat navigation in the West, from its first establishment to the present time—commerce and trade of the Western States—remarks on emigration—with a variety of minor subjects connected with the population, trade, agriculture, and prospects of the Western States.

The skill of Mr. Hall as a writer—his long familiarity with the western country—his accuracy and his research, cannot fail to render this a valuable publication.

SOCIETY is cemented by laws, upheld by religion, endeared by manners, and adorned by arts.

## MISCELLANY.

THE ARISTOCRACY OF ENGLAND IN THEIR SOCIAL RELATIONS.—The following are extracts from a pamphlet published under the name of "Isaac Tompkins, gent.," ascribed to Lord Brougham.

"The nobility of England, though it forms the basis and bulk, forms not the whole of our aristocratic body. To all practical purposes we must include under that name all their immediate connexions, and even all who live in the same circles, have the same objects, and from time to time attain the same privileges. The law of the constitution is, that only a peer's eldest son succeeds to his father's honors, and therefore we constantly hear it said that all the rest of the family belong to the body of the people. Nothing can be more true as regards legal rights—nothing more false as regards political and social bias. It is certain that the eldest son alone is deemed by our institutions to be born a lawgiver, a senator, and a judge; that he alone, be he ever so ignorant, stupid, and vicious, is allowed to decide upon the great questions of policy and of jurisprudence, and to sit in appeal upon the decisions of all the legal tribunals of the country, and to judge without review all his fellow-citizens for property, liberty, limb, and life. These high functions are so essentially inherent in him, that no bankruptcy, no idiocy (short of being found lunatic by commission,) no criminality, can deprive him of his judicial and legislative attributes. He may have committed felony, and been transported—or perjury, and been pilloried—or fraud, and been on the treadmill; yet, the day after his sentence expires, he may take his seat next the Lord Chancellor or the Archbishop of Canterbury, and turn by his vote the fate of a great measure for diffusing universally the justice which he has contemned and outraged; as indeed one voice threw out the Local Courts' Bill: one peer who opposed it had stated his interests to be affected by the measure, being personally possessed of a private jurisdiction.\* An act of Parliament is required in such a case to disqualify the hereditary functionary; and, accordingly, a peer in Ireland, having been convicted of taking bribes to decide a cause in the House of Lords there, an act was passed to prevent him from afterwards judging, but he voted on all laws.

\* That all these high, precious, grievous, absurd and revolting privileges are confined to the eldest sons of peers is certain; it is equally certain that a more gross mistake never was committed than theirs who for this reason affect to consider all the younger branches of noble families as equal with the rest of the people. Equal they are in law: they can only use and be used like their neighbors; they pay taxes like them; they cannot ride down the peasant or the shopkeepers with impunity: but so neither can the peers themselves. And yet who shall say that, except privilege of arrest from debt, and the power of sitting in Parliament and as judges, there is any real difference existing by law between the eldest son and his brothers, further than there is between a rich man and a poor? All belong to the same estate; all are alike a favored race in the Government and in society; all have advantages unknown to us of the common people; and therefore all constitute the body of aristocracy in fact, be the law ever so plain in the eldest son's favor.

"The same remark applies to all persons who, from their fortune and education, live with noble families habitually. They are admitted to the same familiarities; they receive the same respect from those who foolishly look up to rank, and yet more foolishly gaze at fashion; they find the avenues to power as well as distinction open to them; they are born even to political supremacy which others earn by working for it and deserving it.—What difference in society is there between a lord's second son, or indeed his eldest, and the son of a rich squire, especially if he be of old family, that is, if his father and grandfather have been squires before him? It is certainly a very great advantage of our constitution that nothing prevents men of no birth from gaining this station by their wealth, and talents, and industry; but still they are, in this most important particular, worse off than hereditary patricians—they have to make their way—to win their spurs; the others start on a vantage ground—they are born spurred.

"What, then, our honest yeoman's son, our worthy tradesman's daughter, may properly ask,

'what is it that gives the aristocratic circles all this extraordinary influence; and first of all, why is the admission into aristocratic society so very highly prized, that we of the middle classes are ready to leave father and mother, and brother and sister, and cleave unto them, if we can only, at the cost of such sacrifices, obtain admittance within their pale?'

"First, it must be admitted that there is a very great, a very real charm, in those circles of society. The elegance of manners which there prevails is perfect; the taste which reigns over all is complete; the tone of conversation is highly agreeable, infinitely below that of France indeed, but still most fascinating. There is a lightness, an ease, a gaiety, which to those who have no important object in view, and who deem it the highest privilege of existence, and the utmost effort of genius, to pass the hours agreeably, must be all that is most attractive.

"After this ample admission, let us add [that whoever, after passing an evening in this society, shall attempt to recollect the substance of the conversation, will find himself engaged in a hopeless task. It would be easier to record the changes of color in a pigeon's neck, or the series of sounds made by an Æolian harp, or the forms and hues of an Aurora Borealis. All is pleasing, all pretty, all serviceable in passing the time, but all unsubstantial. If man had nothing to do here below but to spend without pain or uneasiness the hours not devoted to sleep, certainly there would be no reason to complain of these coteries. But if he is accountable for his time, then surely he has no right to pass it thus. Compared with this, chess becomes a science, draughts and backgammon are highly respectable. Compared with this, dancing, which is exercise, and even games of romps, are rational modes of passing the hours. Compared with this, it is worthy of a rational being to read the most frivolous romance that was ever penned, or gaze upon the poorest mime that ever strutted on the stage.

"The want of sense and reason which prevails in these circles is wholly inconceivable. An ignorance of all that the more refined of the middle, or even of the lower classes, well know, is accompanied by an insulting contempt for any one who does not know any of the silly and worthless trifles which form the staple of their only knowledge. An entire incapacity of reasoning is twin sister to a ready and flippant authoritative denial of all that reason has taught others. An utter impossibility of understanding what men of learning and experience have become familiar with stalks hand in hand insolent and exulting, with a stupid denial of truths which are all but self-evident, and are of extreme importance. Every female member of this exquisite class is under the exclusive dominion of some waiting maid, or silly young lover, or slander-mongering newspaper; and if not under the sway of one paper, lives in bodily fear of two or three.—Bribes, entreaties, threats, are by turns employed to disarm these tyrants; and however tormented the wretched victim may be, she is forced by some strange fatality, or propensity, to read what most tortures her.

"Indeed, the relations of this aristocratic class with the press form one of the features most illustrative of the aristocratic character, piquant as it is with all the caprice and waywardness, the unreasoning, and often unfeeling propensities, the alternate fits of blindness to all danger, and alarm where all is safe—in short, all that goes to the composition of a child, and a spoiled child.

"That their encouragement is confined to the vilest portion of the press has long ago been affirmed, and is not denied. The respectable journals are no favorite reading of theirs. The newspaper that fearlessly defends the right, that refuses to pander for the headlong passions of the multitude or cater for the vicious appetites of the selecter circles, that does its duty alike regardless of the hustings and the boudoir, has little chance of lying on the satin-wood table; of being blotted with ungrammatical ill-spelt notes, half-bad English, half worse French, or of being fondled by fingers that have just broken a gold-wax seal on a grass-green paper. But more especially will it be excluded, possibly extruded, from those sacred haunts of the Corinthian order, if it convey any solid instruction upon a useful or important subject, interesting to the species which the writers adorn, and the patricians do their best to degrade. Even wit the most refined finds no cho in such minds; and if it be used in illustrating

an argument, or in pressing home the demonstration (which it often may be), the author is charged with treating a serious subject lightly, and of jesting where he should reason. Broad humor, descending to farce, is the utmost reach of their capacity; and that is of no value in their eyes unless it raises a laugh at a friend's expense. Some who have lived at court, and are capable of better things, say they carefully eschew all jests; for princes take such things as a personal affront—as raising the joker to their own level, by calling on them to laugh with him. One kind of jest, indeed, never fails to find favor in those high latitudes—where the author is himself the subject of the merriment. Buffoonery is a denizen in all courts, but most commonly indigenous; and after the court's example, patrician society is fashioned. It is not in the true aristocratic circles that any one will adventure the most harmless jest who would not pass for a Jacobin or a Freethinker. He may make merry with the led-captain or the humble companion, or possibly the chaplain (though that was rather of the olden time, before the French Revolution had taught the upper orders to pay the homage rendered by vice to virtue, without acquiring piety or morals.) Any other kind of wit rather indicates, if tolerated, that the adventurous individual has found his way thither from the lower latitudes of the liberal party.

"From a contemplation of the aristocracy, the result of sorrowful observation, not of irritable displeasure, we naturally turn to its lamentable but inevitable consequence. Can society long remain in this most unnatural state?

"\* No charge rested on the noble lord; but it is given as an illustration. A clause in the bill had exempted his court.

"† This perfection of our mixed constitution (the envy of surrounding nations!) is thus described by a zealous Church-and-King-man—the Tory Dean Swift—as far as decency allows an extract from the Rev. author's work:—

"I told his Honor that nobility among us was quite a different thing from the idea he had of it; that our young noblemen are bred from their childhood in idleness and luxury; that as soon as years will permit, they consume their vigor and contract odious diseases among \*\*\*\*; and when their fortunes are almost ruined, they marry some woman of mean birth, disagreeable person, and unsound constitution, merely for money, whom they hate and despise; that the productions of such marriages are generally scrofulous, rickety, and deformed children, by which means the family seldom continues above three generations, unless the wife takes care to provide a healthy father among her neighbors or domestics, in order to improve or continue the breed. \* \* \* The imperfections of his mind run parallel with those of his body, being a composition of spleen, dullness, ignorance, caprice, sensuality, and pride: Without the consent, adds the Dean, 'of this illustrious body, no law can be enacted, repealed, or altered; and these nobles have likewise the decision of all our possessions without appeal.' No one can deny that this is a most exaggerated and even false as well as disgusting representation. Yet this same very Rev. divine cants you for an hour by the clock, 'on the 30th of January, 1726, being Sunday,' about 'the blessed martyrs,' and 'the blasphemies of the Puritans, who dispensed with a House of Lords.' Verily, he should have served under the present Ministry, and with the supporters of the trustworthy handed interest, which has lately covered itself with such glory!"

A REFLECTION.—Round the idea of one's mother the mind of man clings with a fond affection. It is the first, sweet, deep thought stamped upon our infant hearts, when yet soft and capable of receiving the most profound impressions, and all the after-feelings of the world are more or less light in comparison. I do not know that even in our old age we do not look back to that feeling as the sweetest we have known through life. Our passions and our willfulness may lead us far from the object of our filial love; we learn even to pain her heart, to oppose her wishes, to violate her commands; we may become wild, headstrong, and angry at her counsels or her opposition; but when death has stilled her monitory voice, and nothing but calm memory remains to recapitulate her virtues and good deeds, affection, like a flower beaten to the ground by a past storm, raises up her head and smiles amongst the tears. Round that idea, as we

have said, the mind clings with fond affection; and even when the early period of our loss forces memory to be silent, fancy takes the place of remembrance, and twines the image of our dead parent with a garland of graces and beauties and virtues, which we doubt not that she possessed. Thus had it been with De Vaux: he could just call to mind a face that had appeared to him very beautiful, and a few kind and tender words from the lips of her he had called mother: but he had fancied her all that was good and gentle and virtuous; and now that he was forced to look upon her as a fallen being—as one who had not only forgotten virtue herself, but in sin had brought him into the world, to degradation and shame—what could be his feelings towards her?—[The Gipsy.]

[From the National Gazette]

The fondness of the Orientals for allegory is well known. One of the most curious instances of it is found in an Arabian poet, who narrates a suit which was pleaded on both sides and judged under an allegorical veil, and which seemed an enigma to those who were not in the secret. The following account of it is abridged from the "Mélanges de Littérature Orientale" of M. de Cardonne.

A Sultan, beholding a beautiful woman from his terrace, fell violently in love with her. Wishing to inform her himself of the sentiments with which she had inspired him, he imposed upon her husband Feiroux a commission to be executed immediately. As soon as he was gone, the Sultan found means to penetrate to the apartment of the beautiful Chemsennissa (a name signifying the Sun of women.)—The lady seeing him enter, and divining his intentions, said to him: 'The lion would deem himself degraded by eating the leavings of the wolf; and this king of animals disdains to slake his thirst in the stream which the dog defiles with his impure mouth.' The Sultan comprehending that he had nothing to hope, retired in such confusion as to forget one of his slippers.

Feiroux had set off with such haste, that he had omitted to take with him the order written by the Sultan; and returning to get it a moment after the letter had departed, perceived his slipper. His jealousy was excited to the highest pitch; but he dissembled it through fear of the Sultan, and resolved to repudiate Chemsennissa. He induced her, accordingly, under a plausible pretext, to go and pass some days with her father, and gave her a hundred pieces of gold. She obeyed; but some time having elapsed without the appearance of Feiroux, she became alarmed, and communicated her fears to her brothers. They repaired together to the Vizier, to learn the reason of his absence. He replied without entering into any explanations, that the dower which had been agreed upon having been paid to Chemsennissa, there were no further questions to be asked. The case was then brought before the tribunal of justice.

The Sultan was in the habit of being present at trials, in order to restrain the Cadis. The brothers of Chemsennissa spoke thus:—"My lord, we leased to Feiroux a delicious garden, a terrestrial paradise; we consigned it to him, surrounded by lofty walls and filled with the finest trees, adorned with flowers and loaded with fruit. He now wishes to give us back this garden, deprived of every thing that rendered it delicious when he received it from us."

The Cadi having commanded Feiroux to assign his reasons, he said—"It is unwillingly that I renounce the enjoyment of this spot, which was dear to me; but one day, whilst walking in one of its paths, I perceived the traces of a lion: fear seized upon my soul, and I preferred abandoning the garden to that terrible animal, to exposing myself to his rage."

The Sultan, who easily understood the enigma, anticipating the Cadi, said to Feiroux—"Return into thy garden, Feiroux; thou hast nothing to fear. It is true that the lion has placed his foot in it, but he has touched none of the fruit; and he left it, overcome with shame and confusion: there never was a more beautiful garden, nor one, at the same time, better guarded and secure from danger."

Feiroux took back Chemsennissa, and loved her still more ardently when he discovered the difficult trial to which her virtue had been exposed without succumbing.

FINE SENTENCES IN HOOKER.—Hooker, in his "Ecclesiastical Polity," says "the time will come

when three words, uttered with charity and meekness, shall receive a far more blessed reward than three thousand volumes written with disdainful sharpness of wit.

**NATURE** is often hidden, sometimes overcome, seldom extinguished. Force maketh nature more violent in the return, doctrine and discourse maketh nature less importune, but custom only doth alter and subdue nature.

**HONOR**—This passion "predominates in every mind, till it has been suppressed by frequent disappointments."

**MEN** in great places are three servants—servants of the sovereign or state, servants of fame, and servants of business, so as they have no freedom, neither in their persons, nor in their actions, nor in their times.

**LOW COMPANY**.—He that sinks into a familiarity with persons much below his own level, will be constantly weighed down by his base connections; and though he may easily plunge still lower, he will find it almost impossible ever to rise again.

**PEDANTRY** proceeds from much reading and little understanding. A pedant among men of learning and sense may be likened to an ignorant person giving an account of polite conversation.

#### DOMESTIC INTELLIGENCE.

**CHURCHES IN THE FAR WEST.**—An Episcopal association has recently been entered into in this city, for raising a permanent fund towards aiding in the construction of churches, in the fastly growing States of the West. The aims and the prospects of this association were admirably explained on Sunday evening at St. Thomas's church, to a large auditory, and the information there communicated, cannot fail of adding both to the means, and the zeal of the associates.

It was stated as the uniform result of inquiries in the western and south western states, that the great difficulty in collecting and maintaining congregations there is, the want of suitable houses of worship. Religious impressions, attachment to the church of their fathers, and the desire again to participate in its rites—all these exist abundantly.—But in a new country, thinly settled, and requiring all the means of all the households to provide for the wants of the hour—there is little or no ability to lay aside money for the construction of churches. The proposition then, is to raise a fund here—to be managed by trustees—from which loans shall be made at a very low interest, or without interest, according to the exigency of the case, towards building churches. These are to be really loans, not gifts, to be repaid as the churches grow, and to be re-loaned again, when needed, at still more distant points.

This seems to us so clearly a just and very unquestionable object of interest to all Protestants, and to Episcopalians in particular, that we so far depart from our usual course in such matters, as to make this notice of it.

[From the Courier and Enquirer.]

**VERY COMMENDABLE COMPETITION.**—Mr. Clark formerly Clerk of the United States House of Representatives, and Mr. Shackford, Sergeant-at-Arms of the Senate, at a late meeting of the Washington Bible Society, entered into a rivalry that resulted very much to the advantage of that institution, and we are glad that the officers of Congress can afford to lay out their money so liberally upon benevolent objects. Mr. Shackford rose in the meeting and moved the following resolution, which was read by Mr. Clark, as President of the Society:

Resolved, (by Divine permission) I will pay to the Secretary of the American Bible Society, for value received, one thousand dollars in four annual instalments of \$250 each, payable on the first day of February, in the years 1836, 1837, 1838, and 1839, without defalcation. (Signed)

J. SHACKFORD.

After a few remarks the President handed the resolution to the Secretary, and the following was found to be appended.

"I will pay the like sums on the same terms."

M. ST. C. CLARK.

**CHOLERA.**—Exaggerated accounts are prevailing of the existence of this disease on the Western waters. St. Louis particularly, was said to be suffering, but the Missouri Republican of 30th ult., asserts that no Cholera exists there at all.

[From the Detroit Journal.]

**GREAT SPECULATIONS.**—Buying and selling is the order of the day. Our city is filled with speculators who are all on tip toe. Several snug fortunes of from ten to twenty thousand dollars, have already been made. Gov. Cass has disposed of the front part of his farm, as far back as Larned street, for one hundred thousand dollars. Extensive improvements are rapidly making in Detroit:—Our city authorities are authorized to obtain a loan of one hundred thousand dollars, and ourselves think seriously of advertising FOR SALE a number of bad debts.

**EXPLOSION AND LOSS OF LIFE.**—A part of the powder mills belonging to Mr. Spencer Cooper, near Lexington, Ky., were blown up a few days since, and a black man, the property of Mr. Cooper, was so badly injured that he died in a few hours. —[Courier.]

**RAILROAD ACCIDENT.**—The Ebenburg Spy states that Conrad M. Strohm, a printer, originally from Lancaster county, Pa. was killed on the Portage railway on Saturday, the 30th ult.

Mr. Johnson, master of a canal boat on the Schuylkill, was instantly killed on Friday last, by the falling of a part of the tow path bridge under which he was passing at Norristown.

**CITRUS PONZINUM OR PINEAPPLE LEMON.**—A very fine citron or lemon of this name, has just been sent to us, by Mr. Thomas Hogg. It weighs 9 1-2 oz. Avordupois, and is 8 1-2 inches in length.

It was picked about two weeks since, before it was perfectly ripe, at Dr. D. Hosack's place at Hyde Park. Its perfume is delicious.

**COUNCIL WITH THE INDIANS.**—We understand that the Secretary of War has appointed Governor Stokes, Gen. Arbuckle, and Maj. F. W. Armstrong, Commissioners on the part of the United States, to hold a Council with as many of the civilized and uncivilized Indians west of the Arkansas as can be convened at the time which shall be appointed to hold it, for the purpose of effecting a general treaty of amity and friendship between all the various nations and tribes roving on our western frontier, including those in Texas, in the neighborhood of the Rocky Mountains, &c. &c. This council can hardly fail to be a very interesting one, as we understand that several thousands of these untutored sons of the forest and of the prairie are expected to attend. It was not known, when the steamboat Arkansas left Fort Gibson, on Thursday last, where the Council will be held—possibly at that post, but more probably at Fort Arbuckle, or perhaps somewhere in the prairie. Three Camanche Indians had been at Fort Gibson several weeks, and excited considerable curiosity. They were highly delighted with the Arkansas and Compromise, which were the first steamboats they ever saw. They were to leave, in a few days, under escort of a company of Dragoons, for the purpose of inviting the various tribes or bands belonging to their nation, to attend the Council. —[Arkansas Gaz.]

**COMMERCE OF NEWARK.**—Under this head, the Daily Advertiser of that place, states the following facts:—

The Committee appointed to inquire into the practicability of a line of Southern Packets at this port, made an interesting report on this subject at the adjourned meeting on Friday evening, of which William Wright was chairman, and Peter S. Duray Secretary. We learn from this document, drawn up after the most careful investigation, that the annual exports of this town exceed in value the immense sum of EIGHT MILLIONS OF DOLLARS: and that the chief amount is shipped thro' New York to southern ports in the United States, South America, and the West India islands, at an expense in freight of upwards of FIFTY ONE THOUSAND DOLLARS annually. The Committee also state, that the present mode of sending goods and produce to the port of New York for shipment, is a direct tax upon the producer and consumers of at least TWENTY TWO THOUSAND DOLLARS per annum,

in cartage, ferrage, &c. From these facts it appears that the annual expense of our shipments exceeds \$73,000, and we believe, from conversation with some of our manufacturers, that this is really less than the actual amount, one third of which, at the least, might be saved by a line of packets freighted at our own wharves.

The Committee concluded with a unanimous declaration, that a line of packets should be established to the Southern States and South America. A Committee was appointed to take the necessary steps to carry the resolution—if possible—into effect.

**NEW CHURCH.**—A new church has been recently organized in the southern part of Brooklyn. A building, we are told, is to be erected forthwith, which will be the fifth Episcopal church in the city of Brooklyn.

From Charleston, we have by the Steam Ship papers of Saturday afternoon last—

The U. S. Branch Bank had subscribed \$1000, to the fund for the relief of the sufferers by the late fire at Charleston.

The Steam Packet David Brown has been withdrawn from the Norfolk route and put on her old route to Charleston, where she is so well known. She leaves on Wednesday, and will continue to leave here every other Wednesday, so that we shall now have alternately with Charleston two steam packets per week, by which arrangement the facilities for travelling will be greatly increased between the North and the South, and most certainly to our merchants and the travelling community in general be of very great and decided advantage. —[Daily Adv.]

**STEAMBOAT ERIC.**—The elegant Troy Steamboat Eric, Capt. Benson, arrived in this city last evening about 9 o'clock on her first trip the present season—having left New York yesterday, at 10 A. M. She has been detained thus long from resuming her place in the regular line of Steamboats between this city and New York, in order to undergo some important alterations in her engines, in the position of her boilers and in her decks. These have now been finished: and she has been, in the mean time, otherwise thoroughly repaired in every part, newly painted and furnished. She is now in complete sailing order, with increased conveniences for the accommodation of the public. —[Troy Wig.]

The report of the Secretary of the Treasury upon the Commerce and navigation of the United States for the last year, gives the following information:—

The whole tonnage of the U. States amounts to 1,606,150 tons. Of which

The distribution in the various cities, &c. is as follows:—

New York city	owns	323,733	New Orleans	69,903
Boston	owns	188,394	Baltimore	50,108
Philadelphia	owns	79,560	Portland	49,018
New Bedford	owns	76,849	Salem	31,877
Nantucket	owns	64,545	Barnstable	30,540

The whole number of vessels of every description built in the U. S. within the year, was 1,188. The whole number of ships built was 144. Of those, there were built—

In Massachusetts	54	In New York	26
In Maine	54	In all other States	27

—[Dai. Adv.]

From Matanzas we have, by the brig Th. Gener papers of the 4th inst. They furnish but little intelligence. A list is published on the 4th. of vessels arriving at, and departing from, that port during the month of May, which gives this result:

Arrivals,	-	-	-	73
of which—American,	-	-	-	54
Departures,	-	-	-	47
of which—American,	-	-	-	33

**LATEST FROM MEXICO.**—By the schz. Gazette, arrived at New Orleans, we have intelligence from Tampico to the 30th ultimo. Gen. Santa Anna entered Zacatecas on the 8th of May, after an obstinate resistance of five hours, by the militia of that city, 800 of whom were killed.

EUROPEAN INTELLIGENCE.

**LATES FROM EUROPE.**—By the packet ship *Emeline* from Liverpool, we have our London papers to and of the 8th ult., and Liverpool papers of the 9th.

The U. S. Frigate *Constitution*, with Mr. Livingston on board, sailed from Havre, it is stated in the London papers, on the 5th May—the *England*, sailed on the 9th from Liverpool. Capt. Maxwell, therefore, has the credit of beating that fine frigate in a passage to the westward.

It is said in some of the French journals, that an attempt was to be made by the Ministry, to add to the House of Peers a proviso to the Indemnity Law, nullifying that of the Chambers. This we deem impossible, seeing that the *Deux de Brégis* adopted, and heartily concurred in M. Fland's proposal.

Mr. Livingston left his Secretary in charge of the legation; but with instructions, as is understood, to leave Paris, if the bill, as it went from the Deputies, should be passed by the Peers.

In England, the chief event is the defeat of Lord John Russell, by the Tories, in Scotch Devolution. It seems to have been unexpected, and to have been followed on the part of his colleagues in the ministry, with an exercise of the King's prerogative in a very unusual manner, by the revocation of the commission to Lord Helyar as Governor-General of India, of Lord Ashurst as Commissioner to Canada, and of Sir Howard Douglas as Governor of the Ionian Isles. All these functionaries had been appointed by Sir Robert Peel, had made all their arrangements, and were on the point of embarking.

Mr. Chm. Grant, created Baron Glenelg, is to be the Governor of India.

In Portugal affairs are quiet. The young Queen attended in person to prorege the Cortes,—and delivered a speech, for which we have no space today.

Both Chambers had addressed her to choose another husband, and she had replied to the Deputies that though she was oppressed by her recent loss, she would take their advice into consideration, and that they might expect from her those sacrifices which the country demands.

In Spain rumors of unconfirmed of battles between Zumalacarray and General Vallen, had been circulating. Lord Elliot had effected one good result, that of infusing more humanity in the mode of conducting the war, and in the treatment of prisoners.

**PARIS, May 5.**—The following are the conditions to which Charles V. is ready to accede, in order to put an end to the civil war:—1. He is ready to abdicate the throne in favor of his son, who should take the name of Charles VI.—2. He is ready to quit Spain as soon as Queen Christina shall leave the kingdom.—3. He promises the immediate betrothing of his eldest son to the Princess Isabella.—4. He recognizes the debts contracted and consolidated since the death of Ferdinand VII.—5. He promises a full and entire amnesty, for political offences.—6. He promises the immediate dissolution of the ancient Cortes to revise and give a legitimate and definitive sanction to all acts since the death of Ferdinand VII., which he will not recognize because they emanated from an illegitimate authority. All the other proposals have been rejected by Don Carlos.—[Election.]

The *Orpheus*, packet ship, from Liverpool, brings us London dates of the 18th, and Liverpool of the 18th ult.

The papers are barren of interest. Parliament assembled on the 12th, but nothing of importance had been done.

Lord John Russell is a candidate for Bristol, in the place of Col. Fox, who has accepted the Chiltern hundred in order to make a vacancy for him.

The Yorkshire election of Lord Mervill was decided in his favor, by a majority of 2800. He goes as Chief Secretary to Ireland.

The Paris dates are to the 14th. The Chamber

of Peers were wholly absorbed in the trials of the Lyons people, and much excitement prevailed in the press and people of Paris. Not a word of our affairs.

Rear Admiral Lewis committed suicide in London, by blowing out his brains. He was 65 years old, and had recently married his maid servant.

Mr. G. Grey, in answer to a question from Mr. Home, stated that Lord Aylmer would be recalled from Canada, and the present Government meant to appoint a commission of two or three persons to proceed to Canada, instead of intrusting the investigation of differences that prevail in the colony to one commissioner, as the late Government had intended to do. Earl Amherst, the commissioner appointed by the late Government, has declined the offer made him by the present Government, to preside over the commission.

**NEW PASSA.**—Friday evening's *Gazette* contained the elevations to the Peerage of Mr. Littleton as Baron Haliburton, of Hatherton, in the county of Stafford; and Lieut.-General the Right Honorable Sir John Byng as Baron Strathford, of Hamdonworth, in the county of Middlesex.

The following is a *Ad.* from the London Morning Chronicle, at the new trade Fair, Alex. Baring.

We understand, that in consequence of some inconvenience occasioned by there being at this moment two Lady Ashburtons, the newly created Peer conveyed to the lady who enjoys a priority of title, a humble request that she would assume the name of Dowager, to avoid any confusion in their correspondence, &c. The noble Lady in question very naturally demurred to the propriety of this unprecedented arrangement under such circumstances; when it was agreed upon to refer the dispute to Carter King-at-Arms; who, after the maturest consideration, has decided that the new made Peer himself is more evidently entitled to the distinction; and as henceforth, therefore, to be entitled the Dowager Lady Ashburton.

**THE REV. JOSEPH WOLFF.**—This renowned traveller has signalled his return to England by giving lectures at Falmouth, respecting the countries he has visited and the adventures he has gone through. The provincial journals tell us that they were crowded; and it seems likely that this *Wolf* will supersede Captain Ross as the *Li-on* of the day.

**FRIGATE.**—The late Ambassador from the U. States to France (Mr. Livingston) is sojourning for a few days with his family at Whaddon's Hotel, in this borough. His Excellency arrived here yesterday in the Constitution American frigate, 50 guns, 400 men, Captain Elliot, bound to the United States from Havre. The Constitution had been off port in heavy weather and fog for several days before she here up. The frigate fired a Royal salute this forenoon, which was answered by the San Josef guard-ship, Captain Falcon, C. B., the commander, having previously gone alongside the Constitution. A Royal salute was also fired from the batteries of the citadel, in compliment to the American Ambassador. The ladies of Mr. Livingston's family have suffered much from sea sickness, and the hon. gentleman himself does not appear in good health. The wind continues contrary, and it is to be hoped that ere it prove favorable for the Constitution to proceed, himself and companions will have received the advantage of repose and change of air.—[London Times, 14th.]

**FATAL ACCIDENT IN Vauxhall-road.**—About three o'clock on Monday afternoon, the neighborhood of Vauxhall-road was thrown into great consternation by a terrific report, followed by a shock by which all the surrounding houses were shaken to their foundations. It was discovered that the shock proceeded from the bursting of a powerful steam-engine boiler on the premises of Mr. Rang, sugar-boiler, which had exploded with such violence as to tear the walls of the building in which it stood to pieces, to lift the roof up into the air, and to hurl down its foundation, and precipitate on the premises in Maguire street, a lofty chimney belonging to the engine-house. The house upon which the materials fell with the most destructive effect, was one occupied by Mr. Acton, in which were himself and his wife, a friend named Minner, and a man who was in an upper room. The shock was so violent as to force in the roof, carrying with it floor, furniture, bedding, &c., and burying all the inmates, with the exception of the female

last mentioned, in the mass. Mr. Acton and his wife had a most narrow escape, being preserved by the joists and timbers falling over them in such a way as to protect them from the superincumbent materials. Mr. Minner was taken from the ruins alive, but was so dreadfully crushed that he died almost immediately. A considerable part of the roof and walls of the engine-house fell directly down, crushing both the engineers, John Selley and William Young, to death, and at the same time killing a laborer of the name of Henry Bennett.

From Mr. Rang's evidence, one of the partners, it appeared that about two months ago he got a new boiler,—the one in question, which was placed on the ground floor of the building, in a part of the sugar-house which had been recently built. On Monday morning, about six o'clock, a fire was lighted under the new boiler. The foreman of the manufactory had told him the boiler would bear a pressure of 30lbs. to the inch. When the steam was up, he fired the pressure at 35lbs., and afterwards reduced it to 30lbs., giving the engineer a caution not to exceed that amount. At two o'clock, having been into the town in the meanwhile, he found the pressure at three he had on the premises, and closing at the gate of the explosion, and saw John Kendrick, and Ashton, deposed it was ordered to be set strength. This tended to the making long, and 5 feet by was proved with a manufactory, and it was considered as was the uniform measure in proof.

John Arneson Burrows, a miller in the employ of Messrs. Rang & Violent, said the engine was short of power the whole day on Monday. About a quarter before three he informed the engineer (Young) about it. He said he could get more steam. Witness saw him again the fire while he was there. On returning to the mill he saw no alteration in the speed, and about a quarter of six hour afterwards the explosion took place. Other evidence was produced, but it merely tended to corroborate the above. The jury immediately brought in a verdict of accidental death.—[Liverpool paper.]

**DISSENTIONS OF COLONIALS AND FRANCE.**—The French have now occupied a part of the country for five years; not only with a view to the foundation of a new nation, the first inhabitant; and what is the beyond the military line the colony is a heavy; the mother country, and thus, as well from the effects Europeans with a ty of the natives, whose vent and impossible to destructive to crops and if practicable, would regenerate; to build a Sahara, would be effectual, and is possible, though the gains would not be worth the candle; and to do what Europeans have mostly done when they came in contact with irreclaimable savages—exterminate them—would not be so easy a matter with the Bedouins as with the Red Indians, the Hottentots, and the Australian.

**SEVERE JOURNALS.**—The French are so lively a people that they just upon every thing; "murder in jest," as Hamlet has it. Of the two post American missionaries destroyed by the savages, they say that they fulfilled their mission and supplied the cannibals with Christian nourishment!!

A few days ago the remains of a farmer were interred at Stevenage, in Hertfordshire, who died many years ago, and bequeathed his estate, worth 400l. a year, to his two brothers, and if they should die, to his nephew, to be enjoyed by them for thirty years, at the expiration of which time he expected to return to life, when the estate was to return to him. He provided for his re-appearance by ordering his coffin to be fixed on a beam in his barn, heated, and the key inclosed, that he might let himself out. He was allowed four days, given beyond the time limited, and not presenting himself, was then buried with Christian burial.

## RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of eight pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, IN ADVANCE. Previous volumes same price; full set of four volumes, \$12.

## RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$2.

## MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, IN ADVANCE. Previous volumes \$1.50 each.

## THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* \* All letters must be postage paid. Eleven numbers sent to one address for \$3,—and TWENTY-THREE for \$10. D. K. M.

## NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given—Vols. 6 and 7, or 1 and 2 new series, \$3 per volume. QUARTERLY JOURNAL OF AGRICULTURE, MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$5, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 220 pages.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher, D. K. MINOR, 35 Wall street, New-York.

## PATERSON AND NEW YORK RAILROAD LINE. SUMMER ARRANGEMENT FOR 1835.

Passengers will leave Paterson at New York, by Jersey City

son at	Ferry at
6 1/2 o'clock, A. M. by Steam	5 1/2 o'clock, A. M. by Horses
8 1/2 " " " " " " " "	8 " " " " " " " "
11 " " " " " " " "	11 1/2 " " " " " " " "
2 1/2 " " " " " " " "	2 " " " " " " " "
5 " " " " " " " "	5 " " " " " " " "

## ON SUNDAYS.

Paterson at 8 1/2 o'clock, A. M. by Steam, 5 " " " " " " " "

New York at 8 o'clock, A. M. by Steam, 9 1/2 " " " " " " " "

Ticket Office in Paterson, corner of Congress and Main streets, opposite "Congress House."

Ticket Office in New York, 74 Courtland st.

Passengers with Tickets will have a preference in seats. Fare from Jersey City, 50 Cents.

Transportation Cars will also ply three times a day each way.

As the Ferry boats do not leave New York precisely at the above times, it is recommended to passengers to procure their tickets and to be at the Ferry a few minutes before the stated hours of departure.

PATRICK COUGHLIN, Agent in New York.

July 17;

## PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-17

## BLOSSBURG AND PAINTED POST RAILROAD, OR TIOGA NAVIGATION COMPANY.

By an Act of the Legislature of the State of Pennsylvania, passed the 14th day of April, 1835, five per cent. interest is guaranteed to the Stockholders of said Company for the term of twenty years.

The books for subscription of the above Stock will be opened at the Exchange in the City of New-York, on Monday, the 22d day of June inst., where one or more of the Commissioners duly authorized will attend.

SAMUEL W. MORRIS,  
URIAH SPENCER,  
ELIJAH WELSH,  
HIRAM BEEBE,  
CURTIS PARKHURST,  
THOS. DYER,  
IRA KILBURN,  
THOS. PUTNAM,  
WM. WILLARD, Jr.  
ASA MANN,  
JOHN KNOX,  
ROBERT TUBBS,

Commissioners.

June 6, 1835—2t

## PHILADELPHIA AND READING RAILROAD.

To Contractors for Excavations and Masonry.

PROPOSALS will be received at Pottsgrove, Montgomery county, between the 7th and 15th of July, for the excavation and embankment, bridge abutments, culverts and drystone drains, of between twenty and thirty miles of the Philadelphia and Reading Railroad, next to Reading.

Persons applying for contracts, will be expected, unless personally known to the Engineer, to present with their proposals, recommendations or certificates, as to qualifications and character.

Plans and profiles of the line, and drawings of the different constructions on it, will be exhibited after the 4th of July, and all other information in relation to the work afforded on application at the Engineer's office at Pottsgrove.

MONCURE ROBINSON, C. E.

Philadelphia, May 30th, 1835.

Jell:Jy10

## TO TUNNEL MINERS, DRILLERS, &amp;c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN RUTTER, Contractor.

The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23—1t

## RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. N-ly 5614

## STEPHENSON,

Builder of a superior style of Passenger Cars for Railroad.

No. 264 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J36 1t

## PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1835.

Spikes are kept for sale, at factory prices, by J. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 223 Water street, New-York; A. M. Jones, Philadelphia; T. Janvier, Baltimore; Degrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

1835

H. BURDEN.

## RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

## PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to the public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. BRASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept. 18 1y

## RAILWAY IRON.

95 tons of 1 inch by 1/2 inch,	Flat Bars in lengths of
300 do. 1 1/2 do. do.	14 to 15 feet, counter sunk
40 do. 1 1/2 do. do.	holes, ends cut at an angle
800 do. 2 do. do.	of 45 degrees, with splitting plates and nails to suit.
800 do. 2 1/2 do. do.	soon expected.

250 do. of Edge Rail of 30 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 24, 28, 32, 36, 40, and 44 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. RALSTON.

9 South Front street, Philadelphia.

Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splitting Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d71mcwv

## SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane. J31 6t

## SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG.

Mathematical Instrument Maker, No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1835.

In reply to thy inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLEY, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1835.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

Germantown, February, 1835.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad. Germant. and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JUNE 27, 1835.

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, I take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed. D. K. MINOR.

New-York, June 27, 1835.

The report of Professor BARLOW, on the transverse strength, and other properties of malleable iron, is unavoidably postponed this week. It will be published in the next number, together with engravings of the instruments with which the experiments were made.

**MAD RIVER AND LAKE ERIE RAILROAD.**—This important link in the internal communication of Ohio, is now about to be undertaken in earnest.

James H. Bell, of this city, a young and accomplished engineer, has been appointed Chief Engineer, for the construction of the work, with directions to enter at once upon his duty. He will leave here, as we understand, in a few days, to commence the undertaking.

This railroad, as some of our readers may know, is intended to connect Dayton—where the Miami Canal from the Ohio to Cincinnati, terminates—with Lake Erie at Sandusky. The length of the line is about 150 miles—the country through which it passes, a fine and fertile one.

At an election for directors of the *Mohawk and Hudson Railroad Company*, held on the 10th inst. in the city of New-York, the following gentlemen were elected for the ensuing year:

Samuel Glover, William C. Redfield, John Laurie, Isaac Newton,\* John M. Catlin,\* of New York, and James Vanderpool, Aaron Thorp, John Y. L. Pruyn, Watts Sherman,\* of Albany.

At a meeting of the directors subsequently, Samuel Glover, was chosen president, James Vanderpool, Vice President, and John M. Catlin, Secretary.—[Argus.]

\* To supply the vacancies occasioned by the resignations of Messrs. Ramsay Crooks, M. Monson, and Gideon Hawley.

**UTICA AND SCHENECTADY RAILROAD.**—We are informed by one of the Directors in this company, that this road will be completed, and the whole line from Utica to Schenectady ready for use by the 1st July, 1836. We shall then be able to go from this city to New York in eighteen hours; the gentlemen who dine here at two o'clock, can breakfast the next morning in New York. This place being the terminating point for the road, a vast accession of travel will take its direction through this city; it will not be extravagant to estimate the increase at four fold the present number of travellers. Utica will become the thoroughfare of the whole west, and likewise of a portion of the south and north in this State. This, however, will not be the only nor principal advantage which will result to us from the accomplishment of this magnificent work. Being brought within so short a distance of N. York, (for the only consideration is *this*;) our large unoccupied water power in this county will naturally attract the attention of capitalists. We have around us some of the most valuable sites for factories and mills of different kinds, which can be found in the State. These can be obtained at moderate prices, are accessible with little trouble, and situated among a dense, moral, and intelligent population, where supplies are abundant and cheap. No investments have made as good returns within a few years past as manufactures. This interest is getting so large, wealthy and industrial, particularly

since the rapid increase of wool growing, that it cannot fail to secure the protection and friendly solicitude of government. This county is already the first manufacturing county in the State, but the investments now made of two millions, bear no proportion to the capacities presented by this county, or to the growing demands of the population.—[Onesida Whig.]

The stock in the Susquehanna Canal apportioned to Philadelphia, was readily taken in Philadelphia on Tuesday last. It is stated that twice the amount could have been obtained in half an hour. This was the case also in Lancaster.

**CANAL STOCKS.**—The Comptroller of the State has given notice that the *Five and Six Per Cent. Stocks* payable on the 1st of July, 1837, will then be paid; and that, mean time, the stock will be purchased by the Commissioners at 5 per cent. premium for the 6 Per Centa., and 3 per cent. premium for the 5 Per Centa., together with interest to the time of surrendering the certificate.

According to the Mercantile, the amount of the stock thus redeemable, is Six Per Centa, \$1,429,670.63; Five Per Centa, \$1,004,949.83. Total, \$2,434,620.46.

**RAILWAYS IN FRANCE.**—The French Minister, M. Thiers, presented last week to the Chamber of Deputies a project of law relative to railroads. He announced that the Government engineers had fixed upon three principal lines for railroads—one from Paris to Havre, by St. Denis, Pontoise, and Gisors, with branch lines to Rouen and Dieppe; a second from Paris to Lyons and Marseilles; and a third from Paris to Lille, Bourdeaux, and Strasbourg. Surveys have, it appears, been made, and plans drawn out for these several lines; but one only, that from Paris to Havre is recommended to be at first undertaken. It is proposed to throw open the work to public competition, and to entrust it to any company who will offer the best conditions, and sufficient securities. M. Thiers further proposes, that the government should adopt a system practised in America, by taking shares in the enterprise on the same footing as private shareholders; and that the Government should subscribe to it to the extent of 12 millions of francs (£500,000 English).—[Lond. Mech. Mag.]

We have too long delayed the following Report. It shows the feasibility of a work which, when completed, as we are confident it will be at an early day, will form another important link in the Grand Atlantic Railroad.

To the President and Directors of the Georgia Railroad Company:

GENTLEMEN: Having completed the survey of the routes for the contemplated Union Railroad, extending from Augusta to Athens, Madison and Eatonton, I have the honor to submit to you, with the accompanying maps and profiles, the following Report on the result of my examinations.

The country, on the generally travelled route between Augusta and Athens, a distance of about 95 miles, possesses a very irregular profile; mounting the high land, from the great valley of the Savannah, in the distance of two or three miles, and subsequently crossing, at frequent intervals, the deep beds of various streams, tributary to that river. A railroad in this direction would only be practicable at an enormous expense, and with the intervention of numerous inclined planes, requiring stationary power.

This route, together with the more advantageous connexion by way of the valley of the Savannah and Broad river, is precluded from consideration by the necessity of providing, in the plan of the work, for an advantageous extension of the two important lines, to Madison and Eatonton. An important object, therefore, in the selection of the route, was to pass as far west as possible, having in view a minimum aggregate distance of the main line and branches.

In the route selected by me, in the survey, as will be seen by reference to the map, this desideratum is nearly attained, with every sacrifice, in the location, to favorableness of profile.

The line to Athens, after leaving the valley of the Savannah, is maintained to within a few miles of the Oconee river, uninterruptedly, on a ridge for the whole distance. Leaving Augusta, it is necessary to pass down the valley of the Savannah to Butler's creek, in order to get an easy ascent to the high land, by following up the valley of the creek.

The line, after thus attaining an elevation of 400 feet in 18 miles, maintains the ridge on which the new Milledgeville road is located, to within a few miles of Sweetwater, a distance of 30 miles. Crossing that stream several miles north of the Milledgeville road, where the valley is of diminished extent, the line preserves the ridge, along the Sand Hill road, leading to Crawfordsville, between the waters of various streams, flowing on the right and left into the Savannah, to Mr. Wright's; a distance of 50 miles from Augusta, and 3 miles north of Warrenton. To Warrenton a branch line could be constructed either for horse or locomotive power.

From this point to Crawfordsville, a distance of 16 miles, the ridge is maintained, dividing the waters of the Ogechee on the south, and of Little river on the north.

Passing directly through the village of Crawfordsville, the profile is highly favorable to Carlton's, 78 miles from Augusta, and 7 miles to the right of Greensboro.

Here the main track, or Union road, terminates, and the branch lines from Athens, Madison and Eatonton intersect.

From this point to Athens, is a distance of 36 miles. The line to Shoal creek fol-

lows the ridge, between waters of the Oconee on the one hand, and Little and Broad rivers on the other, passing by Beman's store, Pence's, Mrs. Dick's, Major Bell's, and Mr. Britton's, following round the head of Big creek, by Col. Thomas', and the Hon. William H. Crawford's. At the residence of Col. Thomas the distance to Lexington is between 3 and 4 miles, to which place a branch could be advantageously constructed. Thus, although the necessity of passing round the head of Big creek adds a few miles to the length of the main line, we gain, by the consequent approximation to Lexington, a shortened line and more favorable profile in connexion with that village.

Leaving Judge Crawford's, the line assumes a southerly direction to Gen. Pope's—thence passing westwardly and crossing Shoal creek, (an inconsiderable depression,) at Col. Jackson's. The route thence will be down one of the head branches of Trail creek, along the valley of that stream, to the Oconee river, opposite Athens.

The river may be crossed at any point which may hereafter be decided upon; but as the distance from the Oconee to Athens is less than half a mile, the ascent, which is 175 feet, must be overcome by means of an inclined plane and stationary power, unless some branch or creek be taken, which, by a circuitous route, might afford a sharp ascent for locomotive use. This is a point which, involving important considerations, other than those of economy in the location, may be best determined by the Board of Directors, hereafter.

The entire length of the line from Augusta to Athens, by the route we have described, is 114 miles.

Before the survey was completed and the minutes collated, we had estimated the distance at 105 miles, not then being aware, from the partial and imperfect information obtained, of the necessity of extending the location through the valley of Butler's creek and round the head of Big creek, which has added several miles to the distance.

The course of the line, in following the serpentine and devious direction of the ridge, is sufficiently regular to admit of easy curvatures of not less than 3000 feet radius.

The profile is generally favorable; there being, with the exception of the rise out of Butler's creek, the rate of which is 1 in 117, and the inclined plane at the Oconee, no other ascents necessary exceeding 1 in 150, or 36 feet in a mile.

For particular information regarding the surface of the country, I refer you to the large profile of the line, made out on a scale of 300 feet to the inch, horizontally, and 30 feet to the inch vertically.

By inspection, it will be perceived that at 18 miles from Augusta the height is 400 ft., reckoning from high water mark in the Savannah river, which is the base or zero of the profiles and vertical measurements.

At Crawfordsville, 66 miles from Augusta, the height is 477 55-100 feet. At Carlton's, where the branch lines unite, the elevation is 450 45-100 feet. At Col. Thomas', 66 64-100 feet. At Judge Crawford's, 613 69-100 feet. At Shoal creek, 608 58-100 feet. In the bed of the Oconee river, 551 3-100 feet. On the floor of the College Chapel in Athens, 628 29-100. The maximum height is about 2 miles east of Shoal creek, where the level is 673 96-100 feet.

The most expensive part of the road, as regards cost of graduation, will be that embracing the pine woods region, although there has generally prevailed an opinion to

the contrary. This is owing to the greater depths of the depressions, and more irregular and broken character of the ridge. The tabular statement, accompanying the estimate, will show at one glance the cost of graduating the different sections, as well as the number of curves, rates of inclination, &c.

It will be perceived that the branch line, to Madison and Eatonton, leaves the main line at Carlton's, 78 miles from Augusta, and pursuing a ridge route, not far from the line of the stage road from Washington, passes directly through Greensboro.—Thence the line pursues the valley of the Beaver dam and Richland creeks, ascending out of the latter at Mr. Griffith's, where the ridge is very low, passing by another small valley into the Oconee river swamp, and crossing the river near the mouth of Sugar creek.

The line then passes up the valley of Sugar creek and Clark's fork, ascending out of the latter at Tompkins'. Here the line forks, one end going to Madison and the other to Eatonton, the distance to the former place being 13, and the latter 8 miles.

The distance from Tompkins' to Carlton's is 25 miles. Thus the whole length of the western branch lines is 46 miles, which added to 114 miles, the distance to Athens, gives 150 miles for the entire length of the contemplated Union railroad.

It will be seen, that although the distance to Augusta by this route is greater from either one of the terminating points, Madison, Eatonton, or Athens, than by the stage roads, yet that the aggregate distance of the entire road is the least practically possible. At the same time, the increased distance of each place from Augusta is about the same.

Thus from Athens to Augusta, by the waggon route generally travelled, is 93 miles; by the line of contemplated railroad, 114 miles;—difference, 21 miles. From Eatonton to Augusta, by the generally travelled roads, 90 miles; by contemplated railroad, 110 5-6 miles;—difference, 20 5-6. From Madison to Augusta, by the nearest travelled roads, 92 miles; by contemplated railroad, 115 4-5 miles;—difference, 23 4-5.

As the valuable rights of the charter secure to the company, for a term of 99 years, the exclusive privilege of railroad between Augusta and these points, no apprehension from a rival road on any of the routes need be entertained, even were a reduction in the distance practicable; and, at the same time, as the charges for transportation will be in proportion to the distance passed over, there can scarcely exist a question as regards the expediency of the proposed plan of location.

The greater the amount of Union road, the less the amount of original capital; the greater the distance from each terminating point to Augusta, the larger the revenue. At the same time, as the aggregate distance is lessened, so will the expense of keeping up the road, and maintaining the transportation, be diminished.

Contrary to my expectations, formed from the appearance of the face of the country, the valley of the Oconee may be crossed, and the branch lines to Eatonton and Madison constructed, without the necessity of applying stationary power in a single instance. This result, so highly and unexpectedly satisfactory, cannot be obtained without some heavy and expensive excavation, the amount of which however ought to weigh but little against the important object in view.

There will be three planes necessary, having an inclination of between 1 in 100, and 1 in 120; one in leaving Greensboro, and descending into the valley of Beaver

Dam; one in descending into the valley of the Oconee, and the other in rising out of Clark's fork at Tompkins'. The depth of excavation at each of these places will be from 35 to 50 feet. This depth of cutting, however, will be necessary but for a short distance, and will afford earth for the high embankment below.

We refer to the estimates and statements for particulars. We shall thus have on the whole Union railroad four planes, including that at the head of Butler's creek, having an inclination of less than 1 in 120. In all these cases a graduation for stationary power could be adopted at less expense, but yet the advantage of preserving uninterruptedly a continuous line of motive power, with the great saving in time, wear and tear of machinery, and expense of maintenance and attendance, makes the original outlay of capital, in the substitution of grades for locomotive power, altogether judiciously and truly economical.

A locomotive of ordinary construction could not ascend a plane of 1 in 120 with more than half the load which she is capable of conveying on a road of short and moderate inclinations, especially where, as in this case, the length of the ascent would prevent any material aid from previous acceleration of velocity.

The rapid improvements which have been, and are daily being introduced into this department of steam machinery, and which promise still greater results than have yet been attained, ought not to be overlooked in cases of this kind, where a decision is to be made between stationary and locomotive power. When Wood, in 1823, declared a rate of speed equal to 12 miles in the hour, as entirely visionary, and out of the question, it was little expected that in a few years afterwards a velocity of 20 miles in the hour would be established as perfectly practicable.

The calculations of the theorist, that the resistance presented to the motion of the carriage on a level railway being equal to the friction, or about 1.240 of the weight, the maximum useful effect of the engine would vary just in proportion to the inclination of the plane from the horizontal against the motion, though correct in principle, is erroneous in practice; inasmuch as where such planes are of short extent, and preceded either by a level or descent, they may offer a resistance of three or four times the amount of friction, without materially impairing the rate of motion preserved in the powerful momentum of the train.

A partial observation of this fact has led to the adoption of the fallacious theory of the undulating railway, which advises a systematic and expensive pre-arrangement of balancing planes, regularly succeeding in alternate ascents and descents, in preference even to horizontal graduations, and with the absurd purpose of thereby establishing and maintaining an additional useful effect in the motive power.

The passenger engines can be made to surmount any of the ascents unaided and without difficulty.

An extra engine, stationed between Augusta and Pepper Hill, could no doubt be profitably employed, when not acting in its capacity of assistant, in the conveyance of pleasure parties to and from the city.

It is not improbable that the healthfulness of the valley of Butler's creek, the broken and refreshing aspect of the scenery, as well as the favorite nature of the conveyance, will create a lively intercourse between Augusta and that section, especially in the summer months.

It is likely that one assistant engine would answer in the valley of the Oconee for the three planes between Greensboro and Tompkins', should it be found good economy to employ one. However, as assistance seldom would be needed, supposing the engines to be of the most powerful construction, unless the train was uncommonly large, in cases where the load was too great, a portion of it would be left at the foot of the plane, on a siding, until the ascent and return of the locomotive.

Powerful freight engines, restricted to a low velocity of 8 or 10 miles in the hour, despatched at frequent and regular intervals, are seldom loaded to the extent of their power; as the amount of freight which they are capable of carrying can seldom be collected in the short intervals of their departure. The Hamburg, a freight engine of the South Carolina railroad, can carry 600 bales of cotton 7 miles an hour, equal to about 95 tons. Yet her portion of freight in the regular course of business will seldom exceed 3 or 400 bales.

The power of the engine exerted at its maximum on the ascents, will often be sufficient to enable her to overcome them with an ordinary load. In cases, however, where the load is a maximum, either the train can be divided at the ascent, or an assistant locomotive used, as we have proposed.

I entertain a strong hope that future examinations, conducted in the most thorough and deliberate manner, may enable us to reduce some of the steep planes of inclination west of Greensboro, at least to a grade of the same rise, with a less amount of deep cutting and heavy embankment. Wherever such reductions may be reasonably expected, I have placed remarks to that effect over the line of graduation on the profile.

The town of Greensboro is 511 52-100 feet above high water at Augusta. Bed of the Oconee, 262 62-100 feet. Ridge at Tompkins', 497 3-100 feet. Madison 564 68-100 feet, and Eatonton 463 84-100 feet.

Having traced the outline of the topography and profile of the country, we have next to consider the general plan of construction which a wise economy would recommend. In grading the surface, the more substantial form of excavation and embankment, instead of piling, as adopted on the Charleston road, will be unquestionably advisable, although in some sections, where the valleys are deep and timber abundant, the truss or bridgework, as shown in plan No. 3, admitting of great substantiability and saving in expense, may be advantageously substituted. Throughout the whole line (with few exceptions) the foundation is of the best character—dry, elevated, and solid, with none of the low and loose sands, treacherous bogs, and extensive swamps of Carolina—peculiarities which, in addition to the inexhaustible abundance of pine timber, made the plan of construction there selected in every respect expedient and judicious. In the pine timbered section of

country through which the route passes, the sand seldom extends to more than 9 inches or a foot in depth, resting on a substratum of a compact clayey material.

If the excavations, which will embrace nearly one half of the whole line of surface, I would recommend in the construction, where the foundation is of undoubted solidity, the adoption of plan No. 1, which consists in the simply putting down of transverse sleepers of pine, locust, post oak, or chestnut, 10 x 10 and 9 feet long at every 5 feet in distance, into which the rails 6 x 9 should be secured in gains 4 1/2 inches deep. The earth excavated, in forming the side drains and trimming the slopes, to be thrown in between the sleepers, until they are entirely covered, and the surface raised to within three inches of the top of the rail.

On the embankments, scantling of a durable material, 4 x 10, in lengths of not less than 20 feet, should be laid in a line under the rails, as a support for the ends of the caps, which will greatly tend to prevent any derangement of the superstructure from slight settlements, or unequal tenacity in the soil of the embankment, (see plan No. 2.)

I am greatly in favor of a large size of caps and rails, in preference to the small dimensions usually adopted. The additional quantity of timber necessary is more than balanced by the greater weight and solidity of the pieces, rendering the road far less liable to derangement and injury, from imperfections in the materials or workmanship. The distance apart of the transverse pieces is less than that of the South Carolina railroad, and greater than that of the northern roads. In the former it is 6 1/2 feet, the size of the rail being 6 x 10, in the latter generally 3 1/2 feet with a rail 6 x 6, and as we recommend 5 feet, with a rail 6 x 9. With the large size of caps in the plan proposed, we shall have an equal degree of stiffness, and a much greater weight of timber. It should be borne in mind that where the rail throughout its whole length rests on earth, as is generally the case on an embanked road, the principal purpose of the sleeper is not so much to afford a support in the foundation, as to confine the rails, and preserve the position of the track.

The comparative amount of timber in the different plans would be as follows:

On the northern roads, for one mile,  
1508 sleepers, 7 x 9, 8 1/2 feet long, placed 3 1/2 feet apart, on a foundation of broken stone, 67,29 1/2  
10560 feet in length of railing, 6 x 6..... 31,680  
98,974 ft.

On the South Carolina road, the dimensions of timber used, and quantity per mile, were as follows:

812 caps, 9 feet long, 6 x 9, pinned on piles  
6 1/2 feet apart..... 32,888  
Railing, 6 x 10..... 33,800  
66,688 ft.

As we propose,

1056 sleepers, 10 x 10, 9 feet long, 5 feet apart, resting on a solid surface of gravel or clay, 79,200  
Railing, 6 x 9..... 67,290  
146,490 ft.

On the embankments, where longitudinal string pieces will be necessary, the amount used on the northern roads is generally the same with that we recommend.

The following is an estimate of the cost of one mile of road, by the plan proposed:

1056 sleepers, 10 x 10, heart pine or light wood, post oak or chestnut, hewed, at 50 cents..... \$528 00  
Laying the same..... 250 00  
Railing 47,520 feet, at \$10 per thousand..... 475 00  
Laying the same, and preparing the surface for the iron..... 375 00  
Spiking down the iron..... 30 00

Preparing side drains, and filling in between  
the sleepers and rails,..... 150 00

On embankments the additional cost\* will  
be as follows:

45,164 feet of lightwood foundation piece  
at \$10..... \$451 60  
Laying the same, and securing down the caps  
with iron pins..... 250 00

Estimate as before..... 1806 30

Amount..... \$2509 80

The route for the first 50 miles from  
Augusta is more or less abundantly sup-  
plied with pine timber, suitable for caps  
and railing. In the balance of the line,  
although the country in many sections is  
extensively cleared, we do not apprehend  
difficulty from the want of timber.

The post oak and chestnut, which enter  
largely into the growth of this part of the  
country, are of well known durability, and  
will make the best of caps and sleepers.  
There is no doubt that the same descrip-  
tion of timber, carefully selected, may be  
made available for railing.

The many mills situated on each side of the ridge,  
upon streams contiguous to the line, may be pro-  
fitably employed for the road, and will no doubt  
prove adequate to the supplying of the sawed ma-  
terial.

The road itself, in the course of its construction,  
will, of course, in many instances, offer a cheap  
and expeditious means in the transportation of  
timber from well provided to badly supplied sec-  
tions.

I here is one point which claims our particular  
attention: the use of stone as a material in the con-  
struction.

Stone is used at the north in several modes of  
construction:—

1st. In blocks, generally about one foot square  
and two feet long, set into the ground, three feet  
apart, longitudinally, in parallel rows, the width of  
the track. These blocks, in some cases, as on the  
Liverpool and Manchester, Camden and Amboy  
railroads, &c., afford immediate support to the iron  
edge rails, in other cases to string pieces of yellow  
or pitch pine, 8 x 6, on which the iron plates are  
fastened. In both cases, the space between the  
rails, or string pieces, is filled up with earth or  
broken stone, which is almost necessary to the sta-  
bility of the track. Here, it will be seen, that the  
string piece, being in contact with the earth, is as  
liable to decay as if it rested upon a wooden sleeper,  
and the only advantage gained, in point of dura-  
bility, is the absence of so much of the perishable  
material as is embraced in the sleeper.

A second plan of using stone, is in long blocks,  
placed longitudinally, in continuous parallel lines,  
in a prepared foundation; giving immediate sup-  
port to the iron plates, and dispensing entirely with  
wood in the formation. This plan of road is seri-  
ously objectionable in practice, owing to the want  
of elasticity in the materials, and the necessity of  
placing the iron plates near the edge of the stone,  
which frequently splits off beneath.

A third plan is an improvement on the above,  
which obviates its difficulties—the placing of a lo-  
cated or patch pine lath, 2 1/2 inches thick, over the  
centre of each line of stone rail, and on this lath se-  
curing the iron plates.

A fourth plan, as adopted on the Quincy road, is  
the simply laying of transverse stone sleepers, on  
which the wooden rails, supporting the iron plates,  
are fastened.

Either of these plans could be adopted on the  
Georgia road, at a great saving in expense; owing  
to the mildness of the climate rendering unneces-  
sary the great expenditures incurred at the north,  
in preparing a foundation to resist the effects of  
frost.

\* The extra cost at the north, using the same di-  
mensions of materials, in preparing a foundation of  
broken stone or gravel for the sleepers to rest upon,  
with the cross culverts and drains necessary to carry  
off the water, would amount, in the lowest estimate,  
to \$1000, and generally to 1500 or 2000 per mile. In  
this country, where frost will not injuriously affect  
the work, this expense is rendered entirely unneces-  
sary.

The main advantage of stone, is low in affording  
stability of foundation, than a permanency of struc-  
ture.

In the plans we have considered, where wooden  
string pieces are used, this object is not fully at-  
tained; because, the perishable material being in  
contact with the earth, increases the tendency to  
decay. On the other hand, if the superstructure  
be elevated above the surface, an adequate support  
is left, to preserve the stability and parallelism of  
the tracks.

To avoid this evil, wood is again resorted to—  
transverse tie pieces being placed at frequent inter-  
vals between the rails. Thus we incur an amount  
of perishable material almost equal to that in the  
ordinary wood construction, with the additional  
expense of the stone supports.

It is known, that timber, elevated above and  
near to the surface, will not last longer than that  
entirely covered in the earth.

Taking all these views into consideration, we  
think it will seldom be found, in this climate, good  
economy to adopt the stone blocks in road making.  
Where rock is abundant, however, and can be  
quarried advantageously, and timber is difficult to  
be obtained, a plan as shown in No. 4, may be  
adopted on solid surfaces. In this plan the stone  
should be got out in as long masses as possible—  
never less than one foot in depth, by 12 or 15 in-  
ches in breadth. These stones should be roughly  
dressed on the upper surface, and laid, as a sup-  
port for the string pieces, in continuous parallel  
lines interrupted at every 30 feet by the introduc-  
tion of transverse sleepers of wood, 12 x 12.—  
The string pieces, 5 x 5, should be laid on the cen-  
tre of the stone surface, and secured at every 3 feet  
by iron spikes, 6 inches by 1-3 inch, driven, through  
the string piece, into a seasoned oak plug, previous-  
ly introduced into a hole drilled in the stone. The  
ends of the string pieces should meet on the wood-  
en sleeper. In order to give the spike a better hold  
in the plug, a cavity should be made to receive it  
of 2 1/2 inches deep in the top of the scantling, by  
means of a 3-4 in. auger. To prevent the settling  
of water in these cavities, they should be plugged  
with wood, after the driving of the spike, and  
covered with pitch or turpentine. The whole  
work should be filled up to the base of the scant-  
ling.

In this plan, the size of the string piece, 5 x 5,  
will be sufficient to preserve uniformity in the top  
bearing, in case of inequalities in the supporting  
surface, whether from defective dressing of the  
stone, partial settling, or otherwise. The expense  
of this plan may be estimated as follows, viz.:

9000 cubic feet of stone sills or slabs 12x12 at 15 cents.....	\$1350 00
264 cross sleepers of wood at every 30 feet 12x12 at 50 cents per piece.....	132 00
Pitch pine, chestnut, or white oak string pieces 5x5, 21,375 feet at \$10.....	\$213 75
1483 lbs. spikes, 6 inches x 1/2 inch at 7 cts..	103 81
Workmanship including putting on the iron plates, filling in, &c.....	1985 00

Amount for 1 mile exclusive of the iron plates.....	\$3084 56
Cost when wood alone is used by plan No. 1 in excavations.....	1806 30

Difference..... \$1278 26

This shows a large balance in favor of the wood  
construction, even with this, which we consider as  
cheap a plan of using stone as can be safely adopt-  
ed.

In regard to the plan of setting in stone blocks,  
at three or four feet apart, and supporting the wood-  
en rails or string pieces thereon, I have already  
mentioned that it is very liable to derangement, and  
will not answer well unless great expense is taken  
in preparing the foundation, and wooden cross or  
tie pieces used.\*

\* A young gentleman, assistant civil engineer, thus  
writes me, regarding the stone construction of a road gen-  
erally considered one of the best in this country. "The

I am convinced, from all I have observed, and all  
I can learn on the subject, that you will not find it  
advantageous to make use of stone extensively in  
your road, unless as a foundation for tram or  
bridge work.

I am confident, that a great expense in embank-  
ment may be saved, by adopting this tram or  
bridge work, as shown in plan No. 3, for the cen-  
tral or lowest parts of deep depressions. Support-  
ed on a solid foundation of masonry, the timber  
will be preserved from decay, for a long period.—  
At the same time, ample space is provided for the  
passage of water through the valley, and sufficient  
altitude frequently attained to allow, where occa-  
sion requires, the connecting of a farm road be-  
neath the work.

The next important point to be considered, is the  
size and shape of iron plates best adapted to our  
purpose.

I would respectfully recommend the use of bars,  
having the dimensions shown in the accompanying  
drawings.

This iron is 2 1/2 inches wide, by 6-8 inch thick,  
with a flang, or rectangular projection, 1-2 inch by  
3-8 inch, the bars tongued at the extremities. The  
spikes 5 inches long by 1-3 in, sunk at every 18  
inches in length a full 1-16 in. below the face of the  
iron. Iron plates of this description will weigh  
about 29 tons, costing \$1450 per mile—adding the  
spikes, 2500 wt. at 7 cts.—\$1625 total, for the iron  
and spikes in a mile.

A small quantity of flanged iron was ordered  
from Liverpool, for the curves of the South Car-  
olina mid road. The iron was placed on a portion of  
the work, and answers an admirable purpose. Its  
great advantage is, in preventing lateral friction,  
between the flange of the wheel and the wooden  
string piece, and also in greatly stiffening the plate;  
thereby preserving a uniformity of surface not  
subject to derangement from slight imperfections in  
the material below. Also, when iron is used of the  
ordinary kind, 1-3 in. or 5-8 in thickness, the great  
weight of the cars, rolling over them at high veloc-  
ities, tends to depress them in the centre, and raise  
the ends, working the spikes loose, and making a  
rigid and expensive system of police, and frequent  
repairs, necessary.

Accidents will be less frequent, friction greatly  
diminished, and the expenses lessened, on a road  
having iron plates such as we recommend. This  
iron may be obtained at Liverpool, at the price per  
ton of the ordinary iron.

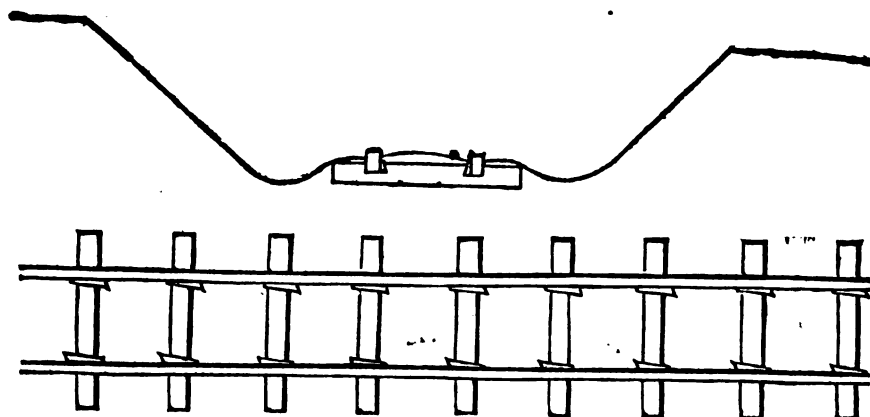

Supposing this style of iron to be adopted, the expense, with the wood construction, in excava- tions would be.....	\$3,430 30
On embankments.....	4,124 00
Where stone is used in the foundation.....	4,509 80

Plan No. 4, on Stone.

Plan No. 3, of Bridge Work.

DUBLIN AND KINGSTOWN RAILWAY.—  
The following is a statement of the number of passengers, of different classes, conveyed along this railway during the first quarter of a year since it was opened, namely, from the 17th of December, 1834, to the 17th of March, 1835:

1st class, fare 1s. each,	10,008
2d do. 8d. do.	72,148
3d do. 6d. do.	94,961

Total number of passengers, 177,117

The whole of this immense number of passengers has been conveyed without the slightest accident of any sort. The receipts during the same period have amounted to £5,283 16s. 8d.—[London Mechanics' Magazine.]

[From the London Mechanics' Magazine.]

*Substitute for Canal Locks.*

SIR,—A short time since I read an extract from the Taunton Courier, (the date and particulars of which have escaped my memory) which announced the opening of some branch canal in that part of the country, of about four miles in length; on which canal machines called "*lifts*," said to have been invented by Mr. Green, the engineer, have been introduced in lieu of the present mode of lockage. Now, if I mistake not, a similar machine was invented as many as twenty years ago, and actually brought into action by a person of the name of Woodhouse. But whether Green borrowed the idea, from Woodhouse, or Woodhouse from Green, it is impossible for me to say. I know it was considered at the time quite a new thing. However, it was found not to answer the intended purpose being too complex, and too expensive for universal adoption. I should be highly gratified if some of your numerous correspondents would produce a drawing and description of one of these "*lifts*," for insertion in your journal; and I am sure there are hundreds besides myself who would be equally gratified.

If I might be allowed to state an opinion, I should say this mode is *inferior* to the old mode of *lockage*. Twenty or thirty tons is a weight which must require machinery of an immense strength and power to transport from one level to another, often differing from six to eight feet; and, as a natural consequence, the time lost must be considerable—much more, I should imagine, than by the present mode *lockage*. To be sure, in short water seasons, like the last, they would be found highly valuable, as at such seasons loss of time is nothing compared with a saving of water. The past has been a trying season for canals, and the expense incurred by many of the companies has necessarily been very great. I have been told it has cost some of them as much as £3 for every lock of water! and that, too, for a considerable length of time!

I am, &c. J. L. J

Bulbourne, March 23, 1835.

In consequence of the extension of the Ohio and Chesapeake canal to Cumberland, the sales of land in that coal region have already advanced 100 per cent.—[Buffalo Adv.]

[From the Journal of the Franklin Institute.]

*Experimental Illustrations of the Radiating and Absorbing Powers of Surfaces for Heat, of the Effects of Transparent Screens, of the Conducting Power of Solids, &c.* By A. D. BACHE, Professor of Natural Philosophy and Chemistry, University of Pennsylvania.

Among the very interesting phenomena of heat, there are many which are with difficulty brought under the eyes of a class, so as to render them satisfactory in each one by the test of sight. The thermometer, even when constructed on a large scale, affords but an inadequate means of rendering evident the temperature of bodies, to those who are distant from the lecture table, and the illustrations made by its use are, at best, rather tame. When the temperatures to be indicated admit of it, lecturers have, in preference to using the thermometer, resorted to the freezing of water, to the melting of wax, to the inflaming of phosphorus, the boiling of water, &c., as more adequate means of rendering evident the temperatures in question.

The instruments about to be described, I have found very convenient for class illustration, and always to afford satisfactory evidence of the positions to be proved. The first instrument is intended to show the powers of different surfaces in radiating and absorbing heat, with other phenomena, which will be referred to in the sequel.

Fig. 1.

To produce a sensibly uniform temperature, a prismatic vessel, A B C D E F G, fig. 1, of sheet iron, of a convenient size, is filled with melted tin, and covered at top by a plate of sheet iron, A F, or, in preference, by a plate of cast iron, of moderate thickness. The temperature of the tin is kept up by an alcohol lamp, H I K, with several wicks, fitting below the box, and between the legs which support it; by this means, the top radiates heat of considerable intensity. I prefer the use of tin, in the box, to that of oil, on account of the greater cleanliness resulting from its use, and because the oil gives off an offensive smell at high temperatures. Boiling water does not give a sufficiently high temperature to produce rapid action in the apparatus, and the greater exactness with which it would yield a constant temperature is not necessary in such an illustration.

A rectangular frame, L M N O, made of dry wood, to prevent its warping, of a small height, L A, and of a length and breadth such as to adapt it to its place upon the cover of the box, A G, is divided by cross pieces of wood into small squares, or rectangular compartments, as *n n*, the upper surface of the frame being perfectly plain, and parallel to the cover, A F, of the box containing the melted tin; this frame is intended to support, without the necessity of contact with each other, small plates of thin metal, or other appropriate material, the surfaces of which are variously coated.

To show the radiating powers of different surfaces, any convenient number of thin plates of sheet lead, or sheet tin, or

mica, are cut to suit the size of the squares, *n n*, of the frame, overlapping the inner edges, but not extending to the middle of the small dividing bars of wood; each one of the plates has one of its surfaces differently coated; supposing them to be of lead, one is coated with lampblack, another brightened by sand paper, or coated with tin leaf, another left tarnished, a fourth coated with gold leaf. Being placed upon the frame, as at *a, a*, with the coated sides uppermost, small bits of phosphorus are placed upon the middle of the plates, and the frame put in its place upon the cover, A F. The surfaces which absorb the heat radiated by the cover, A F, being the same, the material and thickness of the plates being the same, the circumstances are alike in each plate, except so far as the upper surface is concerned; the plate which is coated with the worst radiator, will become warm first, and the phosphorus will melt first upon it, and, generally, the order of melting of the phosphorus will indicate the inverse order of the radiating powers of the surfaces. As the heat radiated from the cover is high, the melting of the phosphorus will be soon followed by its inflaming, and the order thus given will hardly deviate from the first; the interference from the film of oxide, which is so annoying in the modification of the apparatus of Ingenhousz, for illustrating the relative conducting powers of bodies, is almost entirely obtained by the high temperature of the source of heat. To avoid injuring the coated surfaces, a thin film of mica may be placed below the phosphorus, the film being large enough to prevent the effect of the spreading of the phosphorus, as it burns.

The plates should be made thin, in order that the results may be mainly dependent upon differences in the radiating power of the surfaces. I have used plates of thin sheet tin, (iron coated with tin,) of sheet zinc, and of glass, with good effect. The effects may be accelerated by coating the under surfaces with lamp black, to promote the absorption of heat; but in that case, care should be taken that the thickness is at least equal to that which produces the greatest amount of absorption.

Instead of the pieces of phosphorus, wax, or other readily fusible material, may be used, as in the apparatus of Ingenhousz; or cones of wood, weighted at the base, and kept upon the plate, with the vertex downward, by a fusible material, may be substituted.

It may happen that the lecture table is so arranged as to render it advantageous to incline the cover, A F, of the box, A G; this will be readily accomplished by making the cover part of the box itself, in which case the melted metal may be introduced through a hole in the higher side; as, for example, in A D.

To illustrate the fact that *absorption and radiation are proportional*, the same square plates, *a a*, &c., may be used; the variously coated surfaces are placed downwards, phosphorus is put, as before, on the upper surfaces, and the frame deposited in its place upon the cover of the box. The phosphorus will now melt in the inverse of the order shown in the first experiment, the plate having the best absorbent surface heating first. If plates of metal be used, their upper surfaces should be bright, for this illustration; but glass, or mica, which will allow the coating to be seen through, is best adapted to the purpose.

The fact that the *radiation, or absorption, of heat, does not take place merely at the surface*, but at a definite thickness, which

becomes very appreciable in good radiators, may be satisfactorily shown by coating the surface of one of the plates with a thin layer of lampblack, and another one with a considerable thickness of the same material. If the coatings be upwards, as in the first illustration, the phosphorus will melt soonest upon the thinly coated plate; if the coatings be downwards, as in the second illustration, the reverse will be the case.

The effect of transparent screens in preventing the passage through them of heat not accompanied by light, may be shown by using, in the same instrument, plates of glass, mica, &c., of equal thickness; theoretically, the differential results are not as free from objections as the former ones; but the fact is illustrated almost unexceptionably, since the phosphorus melts first at the surface of the plate, which it would not do if the plate were cool, and the fusion resulted from the absorption, by the phosphorus, of the heat which had passed through the screen of glass, or mica.

These illustrations I have tried repeatedly, and successfully; there are others of a more refined character, which I have not yet had an opportunity to attempt, but which, I doubt not, might be carried out very easily. The first of these is the curious property discovered in rock salt, by M. Melloni, of permitting the passage of heat of low intensity, as freely as that of high; a piece of phosphorus placed upon the salt, and another upon a thin film of mica, the under surface of which should be coated with lampblack, just above the plate of rock salt, would serve to show this property. That transparent plates of mica are only partially diathermous, would be shown in a similar way, and, in fact, by the relative periods of fusion of the phosphorus just above the plate, and of that upon it, a notion of the relative quantities of heat stopped and transmitted might be furnished.

Another illustration which I have tried with success, is that of the want of specific effect of color on the absorption of non-luminous heat: a fact which some researchers, undertaken by Professor Courtenay and me, and not yet published, indicate. On coating the plates on one side with lampblack, plumbago, white lead, chalk, prussian blue, vermilion, &c., it will be found that the phosphorus melts upon them without regard to the order of color. Care should be taken that the thickness of the coatings is such as to give to them each the maximum radiating or absorbing power; a thickness which will differ for each material, but which may, for all, be very easily exceeded.

By a change in the character of the plates, this instrument may be used to advantage in showing the experiment devised by Franklin, and executed first by Ingenhousz, for indicating the relative conducting powers of solids for heat.

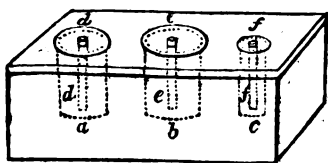

That the experiment just referred to does not truly give the relative conducting powers of bodies, can, I think, be clearly demonstrated, notwithstanding that it is found, in all the books, in juxtaposition with the very elegant and accurate method proposed by Fourier; with the explanation of its intrinsic defects, it may be, however, still admitted as a general illustration. To apply the instrument, plates of the same thickness of the substances to be tested, as, for example, of tin, iron, lead, copper, pottery, wood, glass, &c., which can be easily obtained in the requisite form, are to be coated on both sides with a thick coating

of lampblack, or other good absorbent and radiator, leaving a small strip of the upper surface bare, to exhibit the nature of the material; the plates having phosphorus placed, on mica, upon them, are put upon the frame, and this is placed on the cover of the box: the order in which the phosphorus fires, gives the same indication as in the apparatus of Ingenhousz. This effect is more rapid than when cones, or rods, are used, especially from the lower temperature of the substance which is commonly used as a source of heat. These remarks do not apply, of course, to the forms of that apparatus in which hot sand is used.

The second instrument to be described is intended to show the common illustration of the fact that bodies have *different specific heats*.

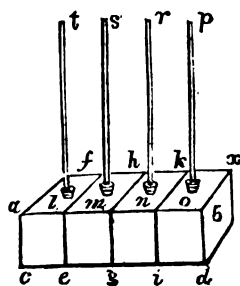

Theoretically, this illustration is, I think, inaccurate, but is *admissible*, like the last; upon this subject, I hope to be able, at a future time, to be more explicit; at present, my remarks are confined to general illustrations. That different bodies require unequal quantities of heat to raise their temperatures through the same number of degrees, is illustrated upon equal weights, or bulks, by subjecting them, when at the same temperatures, to the same source of heat, and proving that they require different times to arrive at the same temperature. This idea is a fundamental one, and cannot too early be inculcated upon a learner. As an illustration, I have three vessels of sheet iron, to contain equal *weights* of mercury, alcohol, and water; these are fastened to a frame, by which they can be dipped into the same vessel containing hot water. An alcohol thermometer, with a column of fluid large enough to be visible at a moderate distance, dips into each vessel. As the heat enters, the thermometer in the mercury rises with great rapidity, that in the alcohol more slowly, and that in the water lags behind both the others. Instead of those thermometers, if a cylinder of any metal which is a good conductor, and has a low specific heat, such as copper, for example, should, after being coated with a varnish of thickened linseed oil to protect the surface, be introduced into each vessel, phosphorus placed on the top would melt and inflame first on the metal which dipped into the liquid having the least capacity for heat. In the annexed cut, fig. 2, *a, b, and c*, are the vessels; *d, e, f*, metallic cylinders resting in wooden, or metallic, or mica, disks, and the whole dipping into a vessel, *m n*, of boiling water. The mercury is so small in bulk, that the influence of this strikes the student immediately; but the idea which he thus catches at, is refuted by the more tardy heating of the water, which is less in bulk than the alcohol.

Fig. 2.

Before the forms of illustration, of the radiation and absorption of heat, already described, had suggested themselves, I had contrived another apparatus, which gave very good results, and may be, by some, preferred to the one already described. A long box, *a b c d x*, of tin, was divided into compartments by partitions, *e f, g h, i k*, &c., and a top soldered upon each, having

Fig. 3.

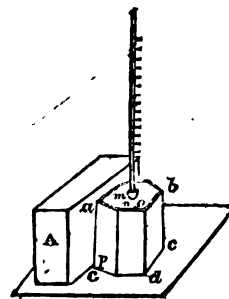

a conical opening, *l, m, n*, &c., to receive a cork, through which a tube, *o p, n r, m s, l t*, &c., passed; these compartments were made as nearly equal as possible, and the tubes entering them were selected of as nearly equal bore as possible; equal measures of colored water were poured through the conical openings into the several compartments, so as to cover the bottom to a depth regulated as will be presently stated. The tubes and corks were now inserted, and cemented; and each cell thus formed an air thermometer, the expansion of the air within driving the colored liquid up the tube entering the cell. That there might be no error from a want of equality in these thermometers, after bringing the liquid to a convenient height in each of the stems, by forcing air into each, or by dropping liquid from a dropping tube into the tube, the whole was plunged into a vessel of water, of a temperature sufficiently above the original temperature of the air within, to give distances on the tubes, readily divisible into equal parts of sufficient magnitude. These degrees were marked by a rude scale, formed by colored threads, tied around the tubes. One surface of the box was kept uniformly bright, or regularly tarnished, or coated; the other, *a d*, was coated with substances of different radiating powers.

The box being placed with the uncoated side towards a vessel of warm water, the heat enters uniformly that side of the compartments, but is radiated differently from the opposite side, and the liquid from the air thermometers is urged more rapidly up those tubes which enter into the compartments radiating worst, and ultimately arrives at a greater height, showing a greater stationary temperature, or temperature of equilibrium, between the heat absorbed and that which is radiated. If the vessel be now turned, so that the variously coated surfaces are towards the source of heat, the liquid in those coated with the best absorbents will immediately begin to rise in the tubes, and that in those coated with the worst absorbents, to fall. That the two lateral compartments are exposed to a greater cooling action than the others, may be an objection to this apparatus; but it is easily obviated, and with it the communication of heat from one compartment to another, by terminating the box at each end by a small compartment, and separating each of the other compartments of a similar space; in fact, convenience alone was the reason for uniting these air thermometers in one vessel.

Another form of apparatus, which is more simple, I have found convenient; but it occupies more time than that last described, in obtaining the same result. A prism of any convenient number of sides, is made into an air thermometer, in the manner described in speaking of the last apparatus; the sides are variously coated; it fits loosely into a prism of the same form,

Fig. 4.

but wanting one side; in the figure, *a b c e*, represents the enveloping surface, and *m n o p*, the air thermometer. To show the different absorbing powers of the different substances, the vessels described are placed as in the figure, before another, *A*, containing hot water, hot sand, or any other convenient source of heat. Supposing the side of the air thermometer, which is the worst absorbent of heat, to be exposed to the source of heat, the air within is expanded, and the position of the liquid in the tube is marked by an index; a better absorbent is exposed, and the liquid rises higher; a worse, and it falls below its original level; the experiment can thus be varied at pleasure. The outer sheath, or covering prism, serves to render the surface, not exposed to the source of heat, uniform in its radiating powers, and to protect those sides which are not intended to be exposed to the source of heat, from the radiation of the vessel, *A*, which, otherwise, would affect them sensibly. If the air thermometer were a rectangular prism, of course the objection just stated would not apply; but the sheath would still be necessary to equalize the radiation from the surfaces not exposed to the source of heat.

To show the radiating powers of the different surfaces, the sheath is turned so that the open side is exposed to the air; the absorption of heat now becomes sensibly constant, and the greater or less height of the liquid in the tube is determined by the less or greater radiating power of the exposed surface.

The order in which the surfaces are exposed may, of course, be so arranged, as not to require the temperature of the source of heat to be kept constant.

Such an apparatus, placed before a stove, would make an admirable illustration in a school, or a vessel of water, colder or warmer than the room, may be used as the radiating or absorbing body. For the tin vessel here described, a common square glass bottle may be substituted, without disadvantage. Even a common glass phial, made into an air thermometer by inserting a tube through a tight cork, into some liquid occupying the lower part of the phial, and provided with a moveable coating of tin foil, gilt paper, writing paper, and paper covered with lampblack, when placed before a fire, or in a room of which the air is warm, when the external air is cold, brought near a window, will afford an interesting and instructive illustration.

Philadelphia, February, 1835.

**TELESCOPES.**—In the county of Worcester, Mass., a self-taught optician resides, who has manufactured some of the best telescopic instruments ever exhibited in this country, so far as it regards distinct vision, under a very high magnifying power. Yet no one patronizes him, to the extent which his merit certainly demands. Every thing within the calibre of his telescopes is com-

plete; and, indeed, all that the astronomer values most, is attained; but the exterior workmanship is rough, inelegant, and clumsy. This circumstance probably operates against them. People are so prone to be influenced by external appearances, that philosophers in rags are never made the companions of kings. A little more attention to this part of the business would certainly have a tendency to call the attention of the learned. At present, the tubes and stands are too abominably ugly.—[Scientific Tracts.]

[From the Albany Argus.]

**THE CANALS.—PROGRESSIVE INCREASE OF BUSINESS AT ALBANY.**—The following table exhibits the amount and the comparative increase of the several articles brought to this city on the Erie and Champlain canals for five consecutive years. By it, the reader will be enabled to judge not only of the progressive increase of the business of the canals, but of the increasing trade of Albany. The great staple of flour, it will be perceived, has doubled within the five years; and coarse grain, lumber and timber nearly trebled.

The additional and complete table for 1834, contains many articles not included in the returns for previous years.

	1830.	1831.	1832.	1833.	1834.
Domestic Spirits,	28,907	18,681	21,985	19,908	20,839
Boards and scantling,	25,832,142	40,569,719	36,090,594	55,338,547	62,103,000
Stingles,	11,810	12,280	13,695	13,433	104,145
Timber,	11,810	12,280	13,695	13,433	795,188
Flour,	336,909	427,021	452,695	734,133	19,070
Provisions,	32,006	16,905	21,874	20,864	17,685
Salt,	48,601	25,306	23,117	22,922	16,944

No. of tons,	104,500	123,742	109,300	123,935	

[From the Albany Argus.]

**CANAL TOLLS.**—In publishing a statement of the amount of tolls collected upon the several state canals, for April and May, there was an omission of the sum collected on the Champlain canal for May, making the total appear about \$14,500 less than it really was.

The amount of toll received upon all the canals for April and May, is \$368,204 10.

The following is a comparative statement of the collections of tolls for April and May, for the last six years, viz:

	April.	May.	Total.
1830,	77,327 12	154,973 95	\$232,300 07
1831,	112,136 84	302,873 25	315,010 09
1832,	37,375 83	212,054 17	249,430 00
1833,	88,606 89	213,583 31	302,189 70

1834,	91,877 58	177,662 26	269,539 84
1835,	122,784 42	214,738 54	337,522 96

#### CHAMPLAIN CANAL.

1830,	133 16	11,165 96	11,299 12
1831,	4,163 15	16,448 14	14,611 29
1832,	464 76	3,517 89	3,982 65
1833,	3,352 90	11,393 98	14,746 88
1834,	5,077 53	16,454 26	21,531 79
1835,	3,137 75	14,569 53	17,707 18

#### OSWEGO CANAL.

1830,	7,50 13	2,058 95	2,808 08
1831,	1,180 29	2,829 06	4,009 35
1832,	464 76	3,517 89	3,982 65
1833,	1,026 84	3,828 33	4,855 17
1834,	1,949 94	2,705 34	4,655 28
1835,	1,378 94	3,870 19	5,249 13

#### CATUGA AND SENECA CANAL.

1830,	956 60	1,905 79	2,862 39
1831,	1,214 19	2,663 42	3,877 61
1832,	392 37	2,101 71	2,494 08
1833,	830 67	2,771 62	3,602 28
1834,	1,094 38	2,887 08	3,981 46
1835,	2,084 71	3,863 76	5,948 47

#### CHEMUNG CANAL.

1834,	100 90	407 17	508 07
1835,	233 59	726 04	959 63

#### CROOKED LAKE CANAL.

1834,	191 10	245 45	436 55
1835,	455 60	461 13	916 73

The tolls collected in April and May, 1835, exceed the collections for the corresponding months of 1833, by the sum of \$42,870 06; and exceed the collections of 1834, during the same time, by the sum of \$67,551 11.

Since 1832, the tolls have been reduced a fraction more than 35 per cent.

**BRUSSELS, May 6.—Railroad in Belgium.**—The iron railroad was inaugurated yesterday. This new sight had attracted an immense concourse of spectators along the whole line of the road. At a quarter past twelve the King being at the station near the Boulevard to witness the ceremony, the departure of the steam carriage was announced by five cannon shot. Immediately three long files of wagons, carrying nearly 1,000 persons, began to move, drawn by the Flèche, the Stephenson, and the Elephant. This extraordinary conveyance was hailed all along the road with the loudest testimonies of surprise and astonishment. The passage from Brussels to Malines took fifty-three minutes.

On arriving before Malines the travellers assembled round the Military Column, the base of which was prepared to receive the medal commemorative of the ceremony, various coins, and the account of the proceedings. The Minister of the Interior, standing in the middle of the assembly, delivered the following speech:

"The presence of an assembly so distinguished and so numerous, attending to witness the ceremony which the King has appointed me to perform, is a solemn testimony of the importance which Belgium, and friendly nations, attach to the establishment of the system of iron railroads decreed by the law.

"This vast enterprise commenced in the fourth year of our political regeneration, will forever attest, what may be expected of a people who love order and liberty, who, notwithstanding the long protracted crisis which accompanied the establishment of its independence, has continued to preserve with the same zeal, agriculture, manufactures, and commerce, which gives splendor and strength to civilized nations; it equally testifies the solicitude of the Government which conceived the idea of it, at the very commencement of its existence.

"I shall not attempt to describe here, all the advantages of iron railroads, they may be summed up in two principal points—saving of time and money.

"By giving prodigious facility to the communications and commercial intercourse, they increase the means of civilization and the sources of prosperity and pleasure. We may already expect, at no very distant period, the connection of our railroads, with those projected in Germany and France. It will be then that Belgium, being able to favor the commercial relation between several nations, will itself obtain great advantages, and acquire new claims to their sympathy.

"Commerce and manufactures, which received a shock from the political commotions, have recovered their activity. The past no longer inspires any regret; the future appears under the happiest aus-

pices, our iron railroad inspires to them a constantly increasing prosperity. Agriculture, the true interest of Manufactures and commerce, will likewise share in these advantages. May the column which we are going to erect in commemoration of the opening of the iron railroad, be at the same time the symbol of a constantly increasing moral union between all the Belgians."

This speech was followed by cries of "Long live the King."

The Minister of the Interior, assisted by his colleagues, then proceeded to erect the first military column (or mile-stone) in the base of which the medals, &c., were deposited and sealed up.

On their return the Elephant took in tow all the 30 carriages that had been drawn by three machines, and would probably have reached Brussels in half an hour had it not been obliged to stop at Vilvorde for a fresh supply of water, the stock having been too much exhausted by the long delay at Malines.

At seven o'clock there was a dinner at Vauxhall, given in the name of the Minister of the Interior, to 200 of the principal persons both natives and foreigners, who had been present at the ceremony.

The *Moniteur* of this morning, published two Royal Ordinances relative to the Railroad, and the tolls to be paid, which are for the account of the Government, in whose hands the Railroad is to remain at present.

**THE EUFRATES EXPEDITION.**—The *Gazette de Smyrne* of the 14th May announces as follows, under date of Constantinople, 5th February:—"The Government has just delivered to the British Ambassador the firmans which he had solicited for the navigation of the Euphrates. The facility with which these firmans have been granted evidently proves that the Divan does not listen to the insinuations of foreigners; for it is well known that representations have been made with a view to discontinue it to accede to this request. In this realization of so vast a project the Porte only thinks of the means of civilization which it will afford to the population of the interior, and every private consideration has given way to this object." There is every reason to believe that the Pacha of Egypt, the promoter of science and commerce, whose influence is no less desirable, will act in a similar spirit. The following passage from "Thornton's India" does not hold out very flattering hopes of the ultimate complete success of the passage to India either by the Euphrates or the Red Sea:—"For several months in the year we could not expect to navigate the former, (the Euphrates), and the latter (the Red Sea) would be unapproachable during the prevalence of the south-west monsoon. If it be not physically impossible for a steamer to make way against the monsoon, her progress must be very slow, and the wear and tear of the vessel and machinery ruinous. If effected at all, therefore, the voyage could not be performed with certainty as to time, and the principal advantage proposed would consequently be lost. There is yet one more serious objection which applies to the two routes; they both traverse countries frequently visited by the plague."

**ICE AND ICE HOUSES.**—It is quite warm enough at this present writing to discourse of ice, but whether it will be when the types are giving publicity to the labors of the pen, depends entirely upon the future, which may be noted as a very wise remark. We intend, however, to say a few words of ice and ice houses, that may interest the reader. There are persons younger than ourself who can remember when the only ice sold in Boston, was brought to the city in parcels of ten or fifteen

pounds in the box of a market gardener's cart, and sold as a very great luxury at a corresponding price. There were then no ice houses in the vicinity, except a few, at gentlemen's country seats, and they were built under ground, and were of small capacity. Within the last twenty years the consumption has become so general and the cost is so small, that ice is no longer deemed a luxury, but one of the necessities of life. The amount exported also from Boston to southern climates is incredible. The art of preserving the ice, is very simple, and in well constructed houses, there is scarcely any loss from dissolution, and it may be preserved for years. We rode out last winter, with Col. Metcalf, of Cambridge, to witness the process of filling one of his ice houses, on the borders of Mystic Pond in Medford, about six miles from the city. The ice house is built entirely above the ground, as is now the well approved custom, even in tropical climates. It is 85 feet long, 50 feet wide, and 25 feet posts, and holds nearly 3000 tons of ice. The house is built of pine boards, and the ice is protected from external heat by filling in the walls, which are a foot and a half thick, with the exhausted bark of tan pits—a non-conductor of caloric that has been found perfectly efficacious. The Mystic Pond Ice House is very happily located, being so situated that the ice may be discharged directly from the house into the boats of the Middlesex Canal, or the cars of the Lowell Railroad, and can therefore be brought to the city at much less expense and loss by waste, than from any other establishment. The pond itself is supplied with water from another pond just above it, which upper pond is fed by such abundant springs, that we are told it never freezes in the coldest season. The water, therefore, is of the purest and most limpid quality. Col. Metcalf has lately loaded with this ice a vessel for Rio Janeiro, and another for Bombay. He has also sent freights to Norfolk, Savannah, and other southern ports. It is transported on the canal, and hoisted on board the vessel by machinery, made for the purpose, with great facility.

The process of cutting the ice, getting it from the water, and storing it in the ice house, is ingenious, but simple. The ice house is built on the border of the pond, and one end projects over the water. At this end there are two openings or doors, which extend from the floor to the roof. When the ice has made to a sufficient thickness, say 15 inches, a spot is selected where it is of the purest, most transparent, and solid quality. It is then marked out into oblong squares, 21 inches wide by 31-2 feet long. At every 21 inches of width, a groove is ploughed, half an inch wide, and 4 or 5 inches deep, by a plough made for the purpose, and drawn by a horse; the ice is then sawed across, at a distance of 21 inches, and one series of blocks being removed, the rest is easily set loose by a staff with a broad, chisel-formed end, driven into the groove, and used as a lever. A canal of a corresponding width to the blocks, is then made from the place where the ice is selected, to the house, and the blocks are pushed along with a staff to one of the doors, where it is received into an iron cradle and hoisted up to the requisite height, when a spring, which has prevented the block from falling off, strikes a projection, and being forced down, the ice slides into the house, and is there received by persons who push it into its place with a staff. From the commencement of the process to the end, the ice is never touched with the hands. The average weight of each block is about 400 pounds, and being all cut of the same form and proportions, they are packed much more closely in the ice-house, or in the hold of a vessel, than when cut out as formerly, with an axe, in a negligent manner.—[Boston Transcript.]

**CULTURE OF PEPPER.**—M. Reynolds, in his voyage round the world, gives the following account of the Culture of Pepper, at Sumatra:

"The pear grows on a vine, or creeping plant, with a ligneous stalk. The blossom is small and white, and the fruit hangs in bunches, or clusters, resembling those of the currant tree, but larger. It is from four to five months coming to maturity.—The berries are at first green and gradually become a bright red when ripe, and soon fall off if not gathered;

"The natives frequently go through their little farms with small baskets, plucking off each bunch as they become ripe. When gathered, it is spread on mats to dry. That which has been gathered at a proper age will shrink least; while those skilled

in the trade will readily distinguish that which has been plucked prematurely, by rubbing it in the hand, when it will impart much dust, and even crumble to pieces.

"The pepper vine runs on poles, like our bean poles; it is planted as our farmers plant corn, about six feet apart. The culture of one thousand plants is occupation sufficient for a man and his wife; 500 plants to a person.

"In ordinary seasons the pepper vine produces two crops in the year. The first is a large one about the month of September, when the sun is crossing the equator, in his declination towards the south; the other in the month of March, when he is returning towards the north. These different crops are generally brought from the interior to the sea shore by rafts of bamboo or other timber, floated on the current of rapid streams."

#### Old Maids; their Varieties, Characters, and Conditions.

Many years have passed since Hayley wrote an "Essay upon Old Maids," in, if our memory be not treacherous, six volumes. An "Essay" in six volumes! Ah! those were the days of hard reading, and of heavy reading—days when the appetites of readers were not more voracious than their digestive organs were powerful—days when we could take two or three duodecimos at breakfast, devour a quarto at dinner, and sleep soundly on a massive folio swallowed at supper. But we have now changed all that, as the French say; and now a puff, a trifle, a cracknel, is found a delightful succedaneum for solid beef and pudding. *Et! bien!* And so, in one light and very amusing volume of little more than two hundred pages, we have here ten chapters inscribed to the female votaries—or victims—of a state of "single blessedness;"—Introductory and Dedictory, Classification of Old Maids in General, Voluntary Old Maids, Involuntary Old Maids, Accidental Old Maids, Inexplicable Old Maids, Literary Old Maids, Honorary Old Maids, Conclusion, and L'Envoy.

Dear amiabilities! can we wonder that you are kind nurses—or that you are fond of cats, dogs, parrots, and Chinese monsters? Is it not thus that you are forced to display your pent up sensibilities? Something you must love—your hearts are overflowing with milk and honey; but mankind, blind to your amiable qualities, meet your advances, as if their most deadly enemies were making covert approaches to destroy their sanctuaries.

The following are the five great "families" into which our lively, pleasant, good-natured author arranges the "class" of Old Maids; each and every one of those families including several species, and those species occasional varieties:—

**GENUS I.**—Ladies whose extreme delicacy, or caution, or coldness, have determined them to live a life of celibacy; every opportunity having been afforded them for marriage.

**GENUS II.**—Ladies possessing every requisite for the connubial state, and who have been anxiously striving to attain it, but, notwithstanding, still remain in single blessedness.

**GENUS III.**—Ladies eminently qualified for matrimonial duties, and who have been repeatedly engaged, but by some accident still remain Old Maids.

**GENUS IV.**—Ladies who remain in a state of virginity, but for which no earthly reason can be assigned.

**GENUS V.**—Literary Old Maids.

A placid stream of kindly feeling meanders delightfully through this volume. Here, for instance, is a sweet and beautiful picture, and true as it is sweet and beautiful. Contrasting the quietude and benevolence of female celibacy with the stormy scenes of a different state, the writer observes:—

"But her life is the oasis of the desert—her heart is a swelling fountain of the purest sympathies—her home is sheltered by the palm-trees of content—and she treads her little round of existence on a verdant carpet, chequered with light and shade, and 'damask'd with crocus, hyacinth and violet in rich inlay.'—For her—

"No blasts e'er decompose the peaceful sky,  
The springs but murmur, and the winds but sigh."

If she does not taste those delights which flow from happy marriage (and there are many such,) when two individuals with moderate desires, and virtuous and well-tempered wishes, combine to produce 'one harmony of bliss,' she invariably shows how correctly she estimates so delightful a consummation,—for where household harmony does reign, there may the old maid be found in all her glory, mingling sweet with sweet, and her heart and af-

flections expanding beneath its genial influence.—Domestic strife is a Tartarus from which she flies, it is a plague spot warning her to depart—but if a father or mother has reached the extreme verge of senility, there she may be seen hovering like a guardian angel, developing in this trying emergency all her treasured affections, and lavishing them on insensible or querulous old age, with all the vigor, the tenderness, and devotedness of a young bride, watching over the shattered health of an adored husband."

But now for the other side of the question, "Involuntary Old Maids;" and with this we believe we must close:—

"The pensive and expectant nymphs have ridden hour after hour, sea-side Jennets, alias donkeys, in hope that their own graces, so admirably set off by the pages of the sagacious and sure-footed quadrupeds, might strike some wandering Lothario; assemblies have been visited—posée parties made up, with especial reference to a 'chance'—fashionable churches regularly attended—balls and quadrille parties sedulously sought after—theatres and all places of public amusement diligently beaten for game—the streets paraded—shady lanes and murmuring streams haunted—dress and undress have been tried—the drawing-room and the boudoir—the dining-room and the library—the sitting-room—and the front window.

Music has been cultivated to fascinate the reluctant ear—painting to captivate the eye—and dancing to enrapture the touch; botany has been studied as an excuse for solitary walks and maiden musing—geology for a rocky nook or a secluded pass—astronomy, that the 'silent hour of night, and the star of love,' might produce their wished for influence—poetry has been read for select tender and touching passages—and history to quote examples of woman's undying affection;—attitudes have been studied—sighs practised—fainting simulated—and a fountain of tears, sacred to dear sensibility, has been most conveniently arranged to pour out on all fitting occasions—

"A shower of glittering pearls."

No chance, however remote, has been neglected, when some fondly supposed admirer—might unfold the passion of his love, scheme upon scheme has been contrived to aim aright—"the rich golden shaft,"—songs have been warbled with soft expectation that they would—

"Give a very echo to the seat

Where love sits throned."

The cunning of their passion has betrayed them into 'dew looks,' surely all sufficient to melt a heart of 'triple brass;' and the vow of eternal truth has been quivering upon their lips, waiting for a signal, however slight, 'to be registered in Heaven.'—Alas—

"Vain—vain have been their wiles—all—vain their tears."

They have 'never told their love,' for nobody has been found,—they have never sworn—

"By the roses of the Spring,  
By maidhood—honor—truth and every thing  
I love thee!"

for none would receive their vow."

We promise the reader—bachelor or married man—maid—wife or widow—a fund of amusement in these pages.—[London Court Journal.]

The curious phenomenon of the Water Spout was witnessed on Sunday evening, about 6 o'clock, by hundreds of our fellow-citizens. It was formed near the lower extremity of the Ohio Falls. According to those, who saw the formation, a cone, in the shape of a trumpet, descended towards the river from a thick dark thunder-cloud, and at the same time, the agitated waters beneath whirled round and ascended with a spiral motion in the form of vapor, till they united with the cone of the cloud, when the whole column moved rapidly and majestically about a mile and a half up the river, where it struck the woods in Indiana, nearly opposite to this city, and disappeared. The whirlwind then passed over a part of Jeffersonville, unroofing houses and doing other damage, but soon struck the river a second time, forming another water spout, which crossed the river to the Kentucky side and disappeared a short distance above Geiger's Mills. On both sides of the river, the whirlwind's path is marked with desolation.—[Louisville Journal.]

The printing establishment of the *Herkimer County Whig*, is offered for sale. The proprietor relinquishes business in consequence of an impaired constitution.

## NEW-YORK AMERICAN.

JUNE 28—29, 1835

## LITERARY NOTICES.

**CONSTANTINOPLE AND ITS ENVIRONS**, in a series of letters, &c. &c., by an AMERICAN, long resident at Constantinople. 2 vols. N. Y., HARPER AND BROTHERS.—Though printed without a name, these very entertaining letters are said to be from the pen of Com. PORTER, now and for some years past, the *Chargé d'Affaires* of the U. S. at Constantinople. The opportunities which that station affords, of seeing the Turks to advantage, the habits of observation of the Commodore, and the no less valuable habit of forming his own opinion on what he hears and sees, impart to these letters a degree of authenticity and originality, as well as anecdote and amusing narrative, that will give to them a wide circulation. They bear, we think, manifest traces of being written as they purport to be, without any view to making a book, and the chief fault we have to find with the publication, is one that lies at the door of the Editor, for not having used occasionally, the liberty of a friend, to correct the negligences of style, which letters written currently so naturally fall into.

**THE ITALIAN SKETCH BOOK**, by an AMERICAN: Philadelphia, Kess & Biddle. We have read this volume with pleasure. It is agreeably written, with scholar like taste, and an eye for all that is beautiful. It is of beaten ground that it, for the most part, treats; and therefore nothing very new or original is to be looked for—beyond that degree of variety and freshness, which the same scene, described and commented upon, by different minds, will naturally produce.

**PELHAM, a Novel, in one volume**, by E. L. BULWER. New York. HARPER & BROTHERS.—This, we presume, to be the first volume of a new and uniform edition of Bulwer's works, and we have no scruple to say, we are glad of it. We do not think Bulwer's style, sentiments, or stories, mischievous, considering the class of works to which they belong, and we do admire his genius, talents, and acquirements. He shews that he has been, and is, a student—but his knowledge of men, and of the human heart, is not less extensive than of books—and by the combined power of the two, he fascinates attention. Whether or not, novels of any sort, are profitable for reading, is not here the question—though on that head too, we have very distinct opinions—but whether—novels of character and real life being now much sought—those of Bulwer are not marked by higher character, and not more objectionable morals, than those of other contemporaries. Of Pelham, for instance, now so handsomely republished by the Harpers—though the author cannot say that it contains

"No line, which dying, he would wish to blot," yet he may say, that it contains much, which read in a wise spirit, may conduce to improvement.

We close our Review to-day—necessarily omitting a notice of several works on hand, including *Three Shoes Robinson*, and the last *American Quarterly*—with the announcement, by the Harpers, which follows.

While acquiescing, as we do most entirely, in the value and expediency of publishing a "series of books," of the character proposed, we would prefer that the selection and preparation of these books, were committed to gentlemen experienced in the condition and wants of our Common Schools, and having the time, the talent, and the disposition to find, or make works, suited to their meridian. It is a most important enterprise which the Harpers are

about to undertake, and—as it may be conducted—capable of great good or evil.

Designedly—it will not be, we are quite sure, for evil—but the task of providing for the youthful mind, is as delicate, as it is important; and to be well discharged, requires not only knowledge of books, but of the process of education, as applied in our schools.

There are in Harpers' Boys and Girls Library, for instance, some capital books, (those by Uncle Philip, especially,) for a "School Library;" but many of the most essential books for such a publication are—so far as we know—yet to be written.

**COMMON SCHOOL LIBRARY.**—The undersigned have read with much interest and pleasure the act recently passed by the legislature in relation to the establishment of a library in each school district throughout the State, for the dissemination of useful and practical knowledge among those who enjoy the benefits of the Institutions provided by law for general education.

To further this most laudable object, they propose to publish a series of books, in small convenient and comprehensive volumes, to be denominated, "The Common School Library of useful and entertaining knowledge," which shall embrace all the most important and interesting subjects, treated in an attractive and perspicuous manner, calculated to arrest the attention of all classes of readers.

The first series, for juvenile or junior classes, and the second for adults and scholars of more advanced age and capacity.

The people of the state of New York, rich in resources, foremost in the arts and commerce, may, by an energetic and judicious application of the salutary law above referred to, add much to their high character for intelligence and public spirit, and greatly benefit the rising generation.

The first volume of both series will be published in the course of two weeks; they will be printed and bound uniformly, in a convenient and suitable manner; and offered to the Trustees, Superintendents, and School Committees at a reasonable price. HARPER & BROTHERS.  
New York, June 12th, 1835.

## DOMESTIC INTELLIGENCE.

**ARRIVAL OF THE CONSTITUTION.**—The United States frigate *Constitution*, Commodore Elliott, having Mr. LIVINGSTON, our Minister to France, and his family, on board, arrived below last evening, and anchored outside of the Bar. She left Plymouth, May 17.

This morning early she got under way, and was beat in over the bar, by the pilot Norris, at about three quarters flood.

She came gallantly up to the city, saluted, and anchored in the North River, off the battery.

Mr. LIVINGSTON and family landed, under a salute from the ship, about 11 o'clock, and proceeded to the house of a relative in Greenwich street.

A considerable number of persons followed Mr. L., whom on reaching his residence, he addressed as follows:

"Fellow Citizens, I feel much happiness at your cordial welcome of my return, and beg to assure you, that during my mission, I have studied all that was due to the dignity of my country, its general interest and welfare."

Three hearty cheers were given and the people dispersed.

Annexed is a list of the officers:

Officers—Jesse D. Elliott, Esq. Commander.  
J. B. Montgomery, 1st Lieutenant, Frank Ellery, 2d do, W. C. Nicholson, 3d do, E. C. Rutledge, 4th do, G. F. Pearson, 5th do, L. M. Powell, 6th do, F. A. Neville, 7th do.  
James Ferguson, master, J. M. Berrian, 2d do.  
James Boyd, Surgeon.  
Henry Ewing, Purser.  
James Everett, Chaplain.  
J. L. C. Hardy, 1st Lieut. Marines, J. T. Sloan, 2d do.  
Passed Assistant Surgeon—Isaac Brinckerhoff.  
Assistant do, R. Woodworth.

J. E. Dow, Professor of Mathematics.

J. H. Prince, Commodore's Clerk.

Geo. A. Thomas, Purser's Clerk.

Passed Midshipmen—J. F. Duncan, James Henderson, W. T. Muse, Charles Steadman, J. W. Bevere, M. Lewis, J. W. Cooke, J. F. Mercer, C. C. Barton.

Midshipmen—R. L. Tilghman, G. W. Randolph, J. B. Lewis, G. T. Sinclair, F. P. Hoban, B. F. Shattuck, W. Ronkendorf, F. S. Haggerty, F. P. Maffit, P. Oakes, W. E. Newton, S. D. Frenchard, E. E. Rogers, A. H. Jenkins.

Boatswain—Robert Whittaker.

Gunner—T. Ryley.

Carpenter—J. A. Dickinson.

Sailmaker—N. C. L'Honnmedieu.

Passengers—Francis J. Lippitt, Esq. of New York; passed Midshipman Wm. Radford.

**CHANGES IN THE ROSTER OF THE MARINE CORPS SINCE FEBRUARY, 1835.**—Lieut. Col. R. D. Wainright. Detached from Gosport, Va., 29d May, 1835, and on leave of absence, since.

Capt. Geo. W. Walker, New York.

First Lieut. Andrew Ross, sloop *Vandalia*.

First Lieut. Geo. F. Lindsay, Philadelphia.

First Lieut. John G. Reynolds, New York.

First Lieut. Henry W. Fowler, Albany, New York, recruiting service.

First Lieut. Francis C. Hall, Philadelphia.

Second Lieut. Geo. W. McDean, flag ship *Hudson*, New York.

Second Lieut. John P. Dieterich, appointment ceased 4th of March, 1835, not having been confirmed by the Senate.

Second Lieut. Louis F. Whitney, New York.

Second Lieut. Fredrick B. McNeill, Boston, Massachusetts.

Second Lieut. William L. Young, Head Quarters. Date of commission, 23d February, 1835.

Second Lieut. William McAdie, Boston, Massachusetts. Date of commission, 3d March, 1835. 1st June, 1835.

The Philadelphia United States Gazette states, that Captain ALEXANDER G. DALLAS has been appointed to the command of the United States naval forces on the West India station.

**GREAT SHIP.**—The following particulars in relation to the "big ship" *Pennsylvania*, now on the stocks at the Philadelphia Navy Yard, are copied from the Philadelphia Inquirer of yesterday.—They were communicated for publication by a sailmaker in the Navy.

220 feet lower deck,  
217 " length aloft,  
190 " length of keel for tonnage,  
56 ft. 9 in. moulded breadth of beam for tonnage,  
59 feet do do outside of wales,  
23 " depth of hold,  
51 " extreme depth amidships,  
3,306 23-95 tonnage; guns, 140,  
18,341 yards duck, one set of sails,  
14,624 " bags, hammocks, boat sails, awnings, &c.; total 32,965 yards.  
11 inches shrouds,  
19 " main stay,  
278 feet mainmast—93 yds. 1 foot,  
110 " main yard,  
82 " topsail yard,  
52 " topgallant yard,  
36 " royal yard,  
10,000 lbs. sheet anchor,  
25 inches do.  
1,531 yards main topsail.

**THE CHEROKEES.**—Gen. Jackson has announced to the Cherokees, that the treaty offering them five millions of dollars for their possessions, is the best he will ever propose to them.—[Journal of Commerce.]

The Newburyport Herald has the following fair hit, at the Monomania, now prevailing alike at the East, the West, the North and the South. The story may not be true—indeed, we dare not quite say we believe it literally ourselves, but it has some truth as an illustration, at least:—[Courier & Enquirer.]

"It is rumored that one evening last week, two paupers escaped from the Bangor Almshouse, and though they were caught early the next morning, yet in the meantime, before they were secured, they had made \$1800 each, by speculating in timber lands."

**THE CHICAGO AMERICAN.**—Under this title we have received to-day the first number of a weekly paper, published in the new city of Chicago, by *Thomas O. Davis*.

It is a very handsome well printed sheet—full of good matter, and showing, moreover, a very goodly array of business advertisements—whereupon we congratulate the Editor. It would, as it seems to us, be a very good medium of advertising for our Pearl-street merchants.

**TORNADO.**—We understand that a most destructive tornado passed up the river, opposite Louisville, on Sunday last, diverged on the Indian side to the town of Jefferson, and again crossed the river to Kentucky. We are not advised of the loss of life, or injury to property sustained.—[Cincinnati Gazette.]

We are indebted to the editors of the Gazette, one of whom obtained the information personally, for the following account of the Tornado, which passed over a part of New Jersey, on Friday last:—

**DESTRUCTIVE TORNADO.**—The city of New Brunswick was the scene, on Friday afternoon last, of a most desolating tornado, which swept over its western section, causing much destruction of property, and, we regret to add, depriving several individuals of life.

As far as we are able to learn, the whirlwind or tornado first made its appearance with a falling of ice in the township of Amwell, near a place called Ringgold's and taking an erratic zig-zag course, spent its fury over Staten Island, in the neighborhood of Rossville, and on the bay, by another fall of large irregular shaped pieces of ice. Its first approach to New Brunswick was from the north-west, passing over Middlebush, about three miles from that place, where the dwelling and barn of John French were laid prostrate with the earth. It thence passed over the farm of David Dunn, about two miles and a half from New Brunswick, whose dwelling was unroofed, and the barn and other out-buildings were razed to the ground. The out-houses attached to the premises of J. G. Wyckoff, in the same vicinity, were also destroyed. The next building which felt its effects was the dwelling of Theophilus Holkham, about one mile from New-Brunswick, the roof of which was blown off. The barns of James Fisher and Abraham Blauvelt, in the outskirts of the city were next blown down, and a small dwelling belonging to Mr. Prevost was nearly destroyed, and the wife of Tunis Sillocks badly injured. The tornado had now reached the hill, "where," according to the New Brunswick Times, "it remained apparently fixed for a minute or two, presenting the appearance of a pillar of fire,—its base resting on the earth, and its top reaching a mass of black clouds. It then took an eastern course, threatening Albany and Church streets, but suddenly changing its direction, swept across the town lot towards the dwelling of Mr. B. Myer, Mrs. Deare, Prof. McClelland, Rev. John Croes, L. Kirkpatrick, Esq. Mrs. Kirkpatrick, and Rev. Dr. Janeway, tearing the roofs off some, making literal wrecks of the barns and out-houses, and either uprooting or twisting off the largest trees—in some instances carrying the latter 20 or 30 paces. It then crossed to the buildings at the head of Paterson, Liberty, Bayard, and Schureman streets, unroofing the house of Mrs. Harrison, levelling the store of Mr. Little, and burying beneath the falling timbers, Nicholas Booraem, Esq. and his eldest son Henry. Both were extricated a short time after—the son in a dying state, in which he lingered until 9 o'clock, when death relieved him from his sufferings—the father is not dangerously hurt. A young lad about 8 years of age, son of Capt. Baird, was also killed near this spot, a rafter from the blacksmith's shop having struck him immediately above the eyes, and almost severed his head. The tornado now swept with increased force across George street, down Liberty, Schureman, and New streets, crossing Nelson to Burnet street, a quarter of a mile in distance, down to the river, unroofing or tearing off the tops of the houses, and sweeping the lower doors and windows from their fastenings. Schureman and Liberty streets, from top to bottom, may be said to be a complete mass of ruins, as is likewise part of Burnet street. The Methodist Church, a brick edifice, is damaged beyond repair, having

been unroofed, and the eastern and southern walls blown down; and the rear wall of the Catholic Church, also of brick, is drove into the body of the building."

The large dwelling of Dr. Janeway, at the junction of George street and the Trenton and New-Brunswick turnpike, was completely unroofed; all the outbuildings razed to the ground, and the beautiful trees surrounding the house twisted off or torn up by the roots. His loss will not fall much short of \$3000.

The dwelling of Littleton Kirkpatrick was also unroofed, and all the out-houses demolished. Estimated loss \$1000. His mother's house was partly unroofed, and other damages.

The large pottery establishment occupied by Mr. Newell, and belonging to the estate of E. G. Mackay, at the corner of George and Liberty-sts. was entirely destroyed, loss \$2500.

The dwelling of James Bishop, corner of Schureman and Burnet streets, was unroofed, and several store-houses, containing a large quantity of corn, was totally destroyed. Probable loss between 3 and 4 thousand dollars.

The buildings of Richard Voorhees, coachmaker, in Schureman street, were entirely demolished, with nearly the whole of their contents, consisting of finished and unfinished work, tools, &c. Loss about \$4000. Under the ruins of this building were found the lifeless remains of widow Catharine Van Arsdale. Mr. Staats Van Dusen was also found under the same ruins, very much bruised; his life was providentially saved by a carriage wheel falling across his body, and thus shielding it from the pressure of the ruins.

Three dwelling-houses also in Schureman street, the property of Nicholas Wyckoff, were very much injured. Loss \$2000. Two dwellings at the corner of Neilson street, belonging to widow Mary Furman, were unroofed and walls much damaged. Loss \$1500. The dwelling of Isaac C. Stelle, in Schureman street, was completely unroofed, and garden fence and shrubbery destroyed. Loss \$1000.

On Burnet street.—Dr. Van Duzen's dwelling unroofed; store-house and stable raised. Loss \$1000. Three or four dwellings, the property of Staats Van Duzen, unroofed, and store-house demolished. Loss about \$2000. Charles Dunham's dwelling unroofed and otherwise injured; several store-houses and out-buildings on the wharf, blown down. Loss from 3 to \$4000. The dwelling and out-buildings, including a store-house, belonging to Brush and Probasco, all destroyed. Loss \$2000.—Two dwellings, the property of Dr. Thomas Fitch, unroofed and other injury. Loss \$1000. The dwelling and cabinet workshop of Matthew Egerton, unroofed, &c. and a ware-house in the rear demolished. Loss from 1 to \$2000.

The Lancasterian School in Schureman street, belonging to the Corporation, was damaged to the amount of \$500.

Schureman street.—F. F. Randolph's workshop completely demolished. Loss \$500 to \$1000. Two dwellings belonging to Matthew L. Egerton, were unroofed and otherwise injured. Loss \$700. Widow Corning's dwelling unroofed and workshop destroyed. Loss \$500. Two dwellings, the property of widow Vreedenburg, damaged to the amount of \$600.

Property belonging to the following named individuals was also more or less injured:

Schureman street.—Miss Rachel Randolph, Walter McHenry, J. W. Stout, Widow Stotoff, Mr. Rolph, Mr. Eldridge, Widow Mary Dunham, A. Agnew, Widow Van Doren, Asa Applegate, E. L. Hardenberg, (Mayor,) Adam Huyler, Borden M. Voorhees.

Burnet street.—Evert Egerton, Widow James Richmond, John Hatfield, Henry Frazer, John Hicks, James B. Cox, John Quick, Michael McCurlogus, Joseph C. Griggs.

New Street.—Dr. F. Richmond, Ambrose F. Randolph, Peter Wyckoff, Judge Hance, Widow Davies, Estate of Robert Boggs, John Taylor, Mrs. John Clark, Mrs. Hagerman, Aaron Hayden.

Neilson street.—Henry Sanderson, H. H. Chittenden, Clara Rogers, Jacob Wyckoff, John Bray, Jr. Dr. Launy.

Prince street.—Rev. Mr. Jones, D. W. Vail, Jonathan Ackerman.

George Street.—Mr. Ackerman, Ralph Voorhees, Solomon Freeman, Wm. G. Dunham.

Liberty street.—Benjamin Clark, Mrs. Van Liew, Garret Nevius.

Henry and James Richmond on Richmond st.,

and Mr. Mersereau, on the Trenton and New Brunswick Turnpike.

From the above details, we feel safe in stating that the number of buildings destroyed and injured cannot fall short of *one hundred and fifty*, and that the loss of property may be estimated at *one hundred thousand dollars*.

Besides those who lost their lives, as above recorded, several persons were seriously injured, and many others slightly.

Among the extraordinary occurrences which took place on this melancholy occasion, the fate of the son of Wm. G. Dunham (a small lad) was the most singular. He was taken off the piazza of the house, corner of New and George streets, carried in the air a distance of 300 yards, and landed on the wharf in Burnet street, having only sustained a slight injury in one of his arms. On being questioned as to his feelings, he stated that he recollected passing through the top of a willow tree, and that the sensation produced by being carried up in the whirlwind was like that of being pulled in contrary directions.

A bedstead was taken from the third story of a house in Schureman street, carried a distance of 200 yards, and landed in Burnet street, without having sustained the slightest injury. A carpet bag and some bedding were carried from the garret of Dr. Janeway's house to the river, a distance of nearly half a mile.

After leaving New Brunswick, the tornado passed down the river a short distance, then took a course across the river, and passing over the farm of James T. Dunn, tore up several trees by the roots, laid all his out-buildings in ruins, without doing the slightest damage to his dwelling. It then passed down to the farm of Joel Randal, and carried away part of the roof and gable end of his dwelling. Thence its course was over Piscataway, a small town, containing about a dozen houses, situated two miles from New Brunswick. Here, every building except two in the place, including the Episcopal Church was demolished. We regret to add, that Mr. Thomas W. Harper, of New York was killed by being struck on the head by a beam.—We understand that Mr. H. had just received the deed of some property which he had been purchasing, and that his visit to Piscataway was for the purpose of making some arrangements respecting it. He was a silver-smith, residing at 31 Rose street, and has left a large family.

The tornado then passed on towards Perth Amboy, where one building was destroyed, and spent its fury on Staten Island as above stated.

Having gone through with the details of this melancholy affair, we now present our readers with the remarks of a friend who was an eye witness of the whole scene, and which will enable them to form a correct idea of this awfully sublime spectacle. He says,—The first intimation I had of the tornado's approach, was the wind blowing in from both sides of the house in which I was sitting. Immediately the cry of fire was raised—I ran to the corner of the street and perceived in a westerly direction at about half a mile's distance a black column moving onward, not very rapidly, which had something of the appearance of a smothered fire, and was mistaken for it. I saw what it was and ran into the house and closed all the windows before it reached us. The whole atmosphere was filled with fragments of timber, &c.—in a moment the house opposite was unroofed, as if it had been covered with paper. The house in which I was, being at the edge of the current, escaped uninjured, save that a rafter from the roof of a house about half a mile distant, thirty feet long, struck the edge of the window, tearing away the brick work and demolishing the sash, and passed into the wall of the room. The track of the tornado was from northwest to southeast, and from a minute investigation of its effects, does not appear to have been of the nature of a whirlwind ordinarily so called. The violence appears to have been produced not from a whirling motion, but from two currents rushing towards each other—at the same time having an onward motion. In the centre of the track the force appears to have been upwards with something of a whirling movement. The facts which substantiate this opinion are these. In the town wherever a building has been moved, if it was at the edge of the current, its direction was inwards; if at the centre, onwards. But these effects are more strongly marked in the woods, where the direction of almost every tree accords with this statement—at the extreme edge the trees are nearly at right angles with the course, sloping more as you

proceed toward the centre, where there is some confusion, but the direction is almost invariably with the current.

**THE TORNADO IN NEW BRUNSWICK.**—In the New Brunswick *Fredonian*, of yesterday, is a list occupying two columns, of the buildings destroyed or injured by the tornado of Friday last—which any one interested may see at this office. That paper adds the following reflections and suggestions, to which we give additional publicity, in the hope of thereby giving to the latter, additional effect.

Recovered, in some degree, from the stunning effects of the late storm, our citizens bear up under their calamity with manly fortitude, and are applying themselves with most commendable zeal and industry, to the relief and accommodation of the families that have been driven from their homes—the removal of the frightful piles of ruins that obstructed the streets—the repairs of such dwellings as can be made tenable—the transfer of merchandise to places of security and sale—and generally, to such other measures as the exigencies of the occasion demand. Mechanics are wanted, and laborers of every description. Lumber and building materials generally, would find a ready sale.—Our sister towns would perform a grateful service, in sparing a part of their carpenters and masons; and if they can find it in their hearts to spare also of their abundance in other respects, they will undoubtedly have their reward. Willing as those among us who have been passed over by the destroying angel, are to do, there will still be room enough for the kindness and liberality of others, not of our immediate circle.

One, at least, of the extraordinary statements connected with this tornado, is thus disposed of:—

We have also the story of a lad 10 or 12 years old, the son of Wm. G. Dunham, being taken up from his father's door at the corner of George and New streets, and carried over the tops of trees and houses at least a quarter of a mile, and landed, with only a slight bruise, on the edge of the river! We believe this marvellous story has no other foundation, than that the boy was impelled by the wind to run down the street towards the river, and was finally thrown down on the wharf. It is beyond our faith to suppose that he could be whirled through the air that distance, and come down not only alive, but almost unhurt! Parts of houses and other articles known to have been thrown that distance, were shivered to atoms.

**TORNADO AT NEW BRUNSWICK.**—We have received by mail the following circular, and cannot more effectually answer the purpose with which it was sent, than by giving to it, as we do, immediate publicity, with the expression of our confident belief, that the appeal it makes, will not be made in vain to this liberal city.

(CIRCULAR.)

New-Brunswick has been visited by a frightful tornado. One of the fairest portions of our city is a scene of desolation and ruin. Charged with that mournful duty by their fellow citizens, the undersigned have made a survey of the devastation, and ascertained, as nearly as practicable, the amount of the positive and direct damage sustained. This they have estimated at SIXTY-ONE THOUSAND DOLLARS, although many judicious persons believe the amount to be considerably more. They will not attempt to swell it, or in aught to exaggerate. Sufficiently painful is the simple truth, in the plain language of the sincere heart.—They feel how vain would be the attempt to give a faithful picture of what they have witnessed, that others might discern the extent of our sufferings.—Nearly or quite one half of the town felt the influence of the tornado, and about one-third of it with disastrous effect. 150 dwellings are in ruins, or have sustained various degrees of injury; and much more than that number of workshops, store houses, barns, and out houses, have been crushed to the earth, or scattered to the winds of heaven.—Lives, too, have been lost—three deaths were the immediate consequence—and many others have been bruised, and maimed, and disfigured, and some so seriously injured as to be of doubtful recovery. For the dead, they are in the hands of a merciful God; it is for the living that our concerns are directed.

A large numerical proportion of the sufferers,

are left in destitute or needy circumstances. They embrace every variety of claim which should call into exercise the sympathies and benevolence of the public. The widow and the orphan—the aged infirm—the common laborer—the hard working mechanic—these are among the number who have felt the severity of the visitation. For these the committee would send forth their plea—for these they would awaken that humane and generous and ennobling spirit, which has so often signalized their fellow countrymen in times of suffering and calamity. They will not plead in vain. They know to whom they appeal, and that the grateful task will soon be theirs of acknowledging the liberal aids which shall yield to the sufferers the "oil of joy for mourning, and the garment of praise for the spirit of heaviness."

J. J. JANEWAY,  
G. S. WEBB,  
F. RICHMOND,  
D. FITZ RANDOLPH,  
MILES C. SMITH.

NEW BRUNSWICK, June 24, 1835.

[From the Gazette of yesterday.]

**THE TORNADO.**—We regret the necessity of being compelled to record more disasters caused by the Tornado which produced such dreadful havoc at New Brunswick. A gentleman arrived yesterday from Gravel Hill, Warren Co., N. J., informs us that it passed within a mile and a half of that place on Friday afternoon, about half-past 5 o'clock prostrating every thing in its course. He says, that when first seen there appeared to be two currents of air, one of which came from a little south of west, and the other from about north, and after meeting they passed off a little east of north. The extent of the tornado was about half a mile in width, and about five miles long. After passing through a thick wood, prostrating every tree within its limits, it reached the farm of Jacob Harris, unroofing his house, and injuring his wife very severely. The next farm in its course was that of John T. Snover, whose barn was unroofed and three barracks blown down. It then passed through his orchard, and out of three hundred fruit trees, only 4 or 5 were left standing. Thence it went through the woods, prostrating every thing, until it arrived at the farm of Andrew Dennis, about three quarters of a mile from Snover's. His house and barn were unroofed and barracks blown down, and in his orchard of two hundred trees, only four were left standing. It then passed through another piece of woods, levelling every thing till it came to the farm of William Shuster (three quarters of a mile.) His house was unroofed, and barn blown down; four or five large rock maple trees were twisted off or taken up by the roots, some of which were carried a distance of 60 yards, and fell upon a cow, which was killed. Thence it passed through another piece of woods to the farm of Adam Warner, (half a mile,) whose dwelling was unroofed, and his barn, barracks, and out-houses were blown down. It passed on about half a mile further, destroying some out-houses and one dwelling, and then terminated abruptly.

Our informant adds, that all the grain and fences in its course were destroyed, as were also all the large trees. Mr. Shuster found a large apple tree on his premises, which had come from the orchard of Mr. Dennis, a distance of three quarters of a mile.

[From the Newark Daily Advertiser.]

**TORNADO AT LITTLE FALLS.**—We hear this morning, that a violent thunder storm and whirlwind, with heavy rain, occurred at Little Falls, about five miles west of Paterson, on the Passaic, in this county, on Friday evening, about 8 o'clock—three hours after the one at New Brunswick. The whirlwind appears to have risen about a mile south west of the Little Falls, near the Bloomfield and Pompton Turnpike, as here an old uninhabited house has been subsequently discovered to be quite demolished. Proceeding in a north easterly direction, it next prostrated an orchard of 25 apple trees, belonging to a Mr. Roberts, about 100 yards from the old house, with the fences in its course. A number of his sheds, and other out houses, a few rods further on, were also totally destroyed. A wagon house, containing a gig and wagon, was also prostrated. The dwelling house, a new, substantial building, escaped, but a large walnut tree before the door was considerably shivered, one of its largest limbs being torn off and carried 200 yards, to a meadow, from which a dozen men could not remove it. Mr. Roberts's loss is about \$600.

About 150 yards from Mr. Roberts's house, a small two story dwelling on the Morris Canal, which here follows the course of the river, was entirely demolished, and thrown into ruins. It is a most remarkable fact, that there were twelve persons in the house at the time it was crushed, all of whom were subsequently taken out of the ruins uninjured. Across the river, in Bergen county, a dwelling house was struck by the lightning, which killed a dog lying on the hearth, and stunned a number of the family. We do not learn that any other material damage was done. The lightning is said to have been fearfully vivid and frequent.

**TORNADO IN WARREN COUNTY.**—The elements appear to be strangely out of point. We learn by a friend from Warren, that a violent whirlwind swept through the upper part of that county on the same afternoon in which so much damage was done at New Brunswick, but probably a few minutes later, say from 5 to 6 o'clock. It appears to have risen somewhere near the Delaware, on the Pennsylvania side, as the first of its ravages that we hear of was in Knowlton township, 15 or 20 miles north of Belvidere, about 50 northwest of New Brunswick. We cannot hear that there was any connection between this tempest and the one which proved so calamitous to the latter place.

It appears to have swept over a space of half a dozen miles, less than a mile in breadth, prostrating whole fields of grain, fences, out-houses, and buildings of every sort, and tearing up, our informant estimates, not less than two thousand forest and fruit trees.

[From the Journal of Commerce.]

**THE NEW BRUNSWICK TORNADO.**—A scientific friend who took the trouble to visit the ground, has favored us with the following notes:—There were two Tornadoes which appeared simultaneously in New Jersey on the afternoon of the 19th instant. That which may be designated by the above name originated at least as far west as the Delaware river. It is known to have struck the earth near the Baptist Meetinghouse in Columbia, Hunterdon county, and was seen several miles west of that place. It here swept through three farms in its destructive course, exhibiting in its appearance, a tunnel shaped form. A gentleman who was within four miles of its track, about twenty miles beyond New Brunswick, supposed he saw the formation of the spout; and he says that he heard for twenty minutes a continuous roll or roar of thunder.

It is worthy of remark, that many observers on and near the line of the Tornado, think they saw its first formation. They witnessed the movements of the clouds in two opposite directions, and then a cone or pillar appeared to descend from the clouds and meet another of similar appearance, ascending from the earth. Such were the appearances; but the real action and organization of the whirlwind doubtless continued much the same, from its first origin to its final disappearance at sea. The effects are certainly much the same in all parts of its track wherever it touched the earth. The motions of the air itself are of course invisible, and of the visible matter, such as clouds and other more ponderous objects affected by the whirlwind, only the lateral or vertical movements can be perceived, according to the laws of perspective, and it may well be doubted whether the violent motion of the real whirlwind around its central cone or vortex is ever seen at all,—but only its effects upon the exterior and surrounding clouds and floating matter. As these clouds in front and in the rear of the tornado, move in exactly opposite directions they of course present the appearance of two currents meeting each other, and when it approaches sufficiently near, the central cloudy pipe or pillar often becomes visible.

The Rev. Dr. Milledollar, who from the College in New Brunswick viewed the tornado with great attention during its progress, says, that it appeared at times to contract very much in its lateral dimensions, assuming a very dark and dense appearance; again it would expand itself and exhibit a more smoky and fiery aspect. This accords well with the appearance of the track, which about a mile east of New Brunswick is narrowed in passing through a field of grain to a width not exceeding one hundred feet, but on striking a wood immediately contiguous, the trees are affected on a width of two hundred feet, showing an expansion in the body of the real whirlwind as it ascends from the earth, while the cloudy or dusty cone which appears in its centre, near the earth, assumes a contrary form.

The general course of the tornado, till within two miles of New Brunswick, appears to have been a little north of east, and from thence till it entered the waters of Rariton Bay, its track seems to have averaged nearly east. The hail, rain, and other ponderous matter discharged from the upper end of the vortex appears to have fallen farther north, at Bridgetown, Staten Island, &c. Two hats taken from New Brunswick fell near Bridgetown. The track affords indubitable evidence that the rotative motion of the whirlwind was from right to left.

The Tornado which passed through Warren county at the same time, and which has been mistakenly noticed in the papers as being the same whirlwind, exhibited for five miles a track of half a mile wide, and would seem to have been in itself a far more formidable phenomenon. The width of the New Brunswick Tornado seems nowhere to have exceeded a few hundred feet, and notwithstanding the great havoc made in New Brunswick and the villages which fell in its way, seems to have been by no means of such magnitude and violence as many of its predecessors, which have spent their fury on more distant and obscure localities.

The tornado which appeared near Paterson, on the evening of the same day, was probably the same which passed through Warren county, if we may judge from its course, and the time of its appearance, which was something more than two hours later than at Knolton, near the Delaware, and we are perhaps indebted to it for the vivid phenomena observed in the city on the same evening.

**DESTRUCTION OF MILLS, BRIDGES, &c.**—An unusually heavy rain fell on Friday last, about twenty miles east of this city, in Lebanon, &c., and in the following night a dam, containing a pond covering about 300 acres, was swept away. The water in its progress, swept away every dam and mill upon the stream, and swept over the shores so as to destroy gardens and fields of grain. The stage could not pass; but by the perseverance of the driver, the mail for the east, by way of Chatham, was conveyed by him on foot, he having passed the stream in a small boat. The stream passed through Chatham and Kinderhook. —[Albany Eve. Jour.]

The Albany Argus, of yesterday, has this paragraph.

**THE WEATHER**—has been cold for several days; and since the heavy showers of Friday, fires have been found necessary for comfort. Yesterday morning, we are informed, frost was discovered in most exposures in this vicinity, and in some instances severe enough to leave its traces behind on vegetables. This, for the summer solstice, or the longest day of summer, is certainly worthy of record.

We learn also, that in the river counties and even on the banks of the river, there was frost on Saturday night, by which the corn was injured.

[From the National Intelligencer.]

Whilst the fields and gardens in this neighborhood are withering under the influence of a protracted drought (to which for two days past has been joined a degree of cold hardly ever before experienced in this meridian, say at sunrise, 50 degrees of Fahrenheit,) our friends in the Western country have been deluged with rain. They seem to have our share of it as well as their own. Witness the following:

PITTSBURGH, June 17, 1835.

During the last week there has been an unusual fall of rain. The rivers are higher now at this city than we have ever known them to be at this season. While we are writing this paragraph, the rain is falling in torrents.

TERRA HAUTE, (Ind.) June 11.

**THE SEASON.**—So far, the season has been one of the most extraordinary within our recollection. During the last twenty days we have had drenching rains—torrents of it—affecting the Wabash and smaller streams to such an extent as to threaten the worst consequences to the farms on the low lands. Already, we fear, much damage is done—and the river still rising! (Tuesday evening, June 9.) On Sunday night, the rain fell in torrents, and continued, with but slight intermission, for eight hours. On many farms the sprouting corn is entirely washed away, even where the influence of the river is not at all felt. Indeed every thing betokens a disastrous season to the grain grower. In addition to these misfortunes, we may add, as a matter local to those interested in the progress of

the National Road, that the operations on that great work are nearly suspended owing to its condition along the whole line. The streams adjacent are out of their banks, and the road, in many places, completely under water. This is a serious public loss, and no less serious private one to the industrious individuals employed as workmen thereon. Some estimate may be formed of the quantity of rain, from the fact, that a steamboat, of 80 tons burden, actually made two trips as far up as Peru, several miles above Logansport. This has been heretofore deemed impracticable.—[Courier.]

**THE FOREFATHER'S ROCK ENCLOSED.**—The Plymouth Memorial states, that the forefather's rock, the landing place of the pilgrims has been handsomely enclosed: "The fabric is a perfect ellipse 41 feet in circumference, consisting of wrought iron bars 5 feet high resting on a base of hammered granite. The heads of the perpendicular bars are harpoons and boat hooks alternately; the whole is embellished with emblematic figures of cast iron. The base of the railing is studded with emblems of marine shells, placed alternately reversed, having a striking effect. The upper part of the railing is encircled with a wreath of iron castings in imitation of heraldry curtains, with festoons; of these there are 41, bearing the names in bass relief of the 41 puritan fathers, who signed the memorable compact while in the cabin of the Mayflower, at Cape Cod, in 1620."

The Bunker Hill Monument, at Boston, is in a state of progression. According to a recent Report of the Monument Association, it is estimated that by November, sixty-six feet will be added to the height of the Monument, making the whole elevation then, more than one hundred feet. With equal progress, next year, the monument can be completed.

The work is said to be done in the most efficient manner—the material is granite.

**SUDDEN DEATH.**—On Monday evening, as Samuel Whitmore, Esq., President of the Greenwich Bank, was walking home to his residence with a lady, he suddenly stopped, and said, "I am very unwell." These were the last words he spoke. He almost instantly fell and expired.

**TO CAPITALISTS.**—A Vermont paper has an advertisement, the substance of which we hasten to lay before the capitalists of the country, as offering a rare chance for a cool investment in real estate. Mr. H. W. Jones, the advertiser, says he has one hundred and ten acres of the first quality of land in Stratton, near the turnpike leading to Troy, which he "will sell to any person who will pay the transfer of the deed, and in addition will warrant most of the season good sleighing from the 15th of October to the first of June, and the climate so pure that it will keep fresh meat perfectly sweet the year round." We do not see how a man could well say more touching the advantages of the premises, or make the terms more eligible. As to the expense of the transfer deed, the owner will probably come down a little in the terms, and pay for that himself.—[Courier & Enquirer.]

**MIRACULOUS ESCAPE.**—Yesterday afternoon, as the granite corner piece for the south west front cornice of the Astor Hotel, weighing three tons, was raised to its height, the derrick broke off near the top, and it fell to the ground. The cornice was broken in two. In its fall it struck, and broke off three or four feet of the projecting piece, in the side wall on Vesey street. It was fortunate that no person was injured by the fall, as many were passing at the time, some of whom very narrowly escaped.—[Sun.]

We received yesterday from Disturnell, 156 Broadway, one of the neatest little articles imaginable. It is a miniature plan of the city of New York, so small that when folded in its neat little case, it occupies no more room than a common visiting card. The lettering though small, is clear and distinct. It is a little bijou, a diamond edition, in which the engraver has proved the perfection of his art.

So say the Times, and we say *ditto* thereto.

An accident occurred on the Worcester Railroad on Thursday. A couple of oxen came suddenly upon the track from behind a barn, and before they

could get out of the way the engine was upon them, knocked them down, and killed them on the spot. The cars were thrown off the road and three hours were lost in replacing them.

**RAILROAD ACCIDENT.**—An accident of a singular character, such as never occurred anywhere before, and such as will never probably occur anywhere again, happened on the Boston and Providence Railroad as the cars were approaching this city, last Saturday, within about four miles of the depot. The nut which confines the bolt by which the break to one of the cars was suspended, became unscrewed by the jarring of the carriage, and the break falling upon the rails under the wheels, the car was thrown from the rails, and being stopped at a speed of about 15 miles an hour, stood up endwise. The car immediately following, mounted this. One of the hands connected with the cars was so badly injured, that his life was at first despaired of, but we understand from one of the agents of the road, that there is now a favorable prospect of his recovery, and that he was yesterday walking about his room. Several of the passengers were somewhat bruised, but no one materially hurt. There were six passenger cars in the train, only two of which were at all deranged.

We understand that the nuts which secure the belts of the breaks, are now all made fast with keys, so that the cars on this road will never be liable to a like accident again, and we presume that this disaster will be a sufficient caution to the directors of other Railroads, to have their breaks secured in the same way.—[Providence Journal.]

**LIABILITY OF POSTMASTERS.**—The Philadelphia Times has the following:—

"The proprietor of this paper last week recovered judgment against a Postmaster for a paper not taken from his office, of which he neglected to inform him. All Postmasters who do so, render themselves liable, and ought to be held accountable."

Every Editor ought to publish this conspicuously, as well for the benefit of Postmasters as themselves.

**EMIGRATION.**—The Venus steamboat left the Steam Packet Wharf, St. Katharine's Dock, at about half-past eight o'clock yesterday morning, with from 320 to 240 female emigrants to take their passage on board the ship Canton for Sydney. The emigrants were, for the most part, fine healthy looking girls, some of them of exceedingly interesting appearance, and almost all of a class much above that in which the distress which prompts to emigration would be supposed to exist.—[English paper.]

**FROM CHILI.**—The ship Nile, Capt. Townsend, arrived at New Bedford on Tuesday, 75 days from the island of Mocha\*—left Talcahuana on the 31st March, one month after the earthquake. The shock of the 20th of February was felt a great distance at sea. Captain Cotton of the ship Leper, informed that he felt the shock very severely six hundred miles from land. The Nile was cruising at the time in lat. 39 15 south, within 8 or 10 miles of the land. The agitation of the ship at the moment the shock was first felt was great, and it was thought the ship had struck—the lead was thrown without finding bottom and Capt. T. wore ship—on the 23d of February another severe shock was felt at the island of Mocha—Capt. Bumpus of the ship Maryland, in lat. 37 35 states that the shaking of the boats and spars over head was so alarming that it was dangerous to stand under them.

A brig arrived at Talcahuana, before the Nile sailed with provisions for the relief of the people who had been deprived of support. The distress was not so great there as was at first anticipated,

\* Mocha is an uninhabited island about 60 miles in circumference situated in lat 38, 40 S. The vicinity of this island is a great resort of ships cruising for right whale.

provisions having come in from the country in abundance. Many of the inhabitants of Concepcion and Talcahuana were employed in rebuilding their houses—some small huts for a temporary shelter.

Capt. Townsend informs that he has been on the coast of Chili a number of times, during the same months, and thinks he never experienced such a scarcity of whales, fish and fowl as there is the present year (1835.) It is the general opinion that the earthquake had driven them from the coast.

**OLDEN TIMES.**—The following extracts from the Journal of an Englishman who visited Boston in the year 1638, show the vast change which two hundred years has produced. The scattered dwellings along the coast have swelled into cities, and the solitary settlers multiplied into nations. But what fancy can paint, or what mind can grasp the probable results of two more centuries, or set bounds to the wealth and power which the Union may have then attained?—[Wheeling Gaz.]

*Extract from the Journal of an Englishman, who visited Boston in 1638, and landed on the island now called East Boston.*

"Soon after we anchored in the harbor, I went on shore at Noddle's Island to Mr. Maverick's, the only hospitable man in all the country; giving entertainment to all new comers gratis.

"Having refreshed myself for a day or two on Noddle's Island, I crossed the Bay in a small boat to Boston, which is rather a village than a town, with twenty or thirty houses, when I presented my respects to Mr. Winthrop the Governor, and Mr. Cotton, the teacher of Boston Church. To Mr. Cotton I delivered the translation of some psalms by Mr. Quarles, the poet. I was civilly treated, and returned to the island in the evening."

The traveller then went to Blockpoint, in the province of *Maine*, 150 miles from Boston; and he says, "he was visited by some of the people of these parts, who told him that a *Sea Serpent* had been seen near Cape Ann. They who passed near it was about to shoot him, when an Indian, who was with them, dissuaded them, saying if he were not killed outright, they would all be in danger.

"One Mr. Milten told me he saw a Triton, or *Merman*, in Casco Bay. These, and some other strange stories I heard, the credit whereof I will neither impeach nor enforce, but I may say with a learned knight, that there are many stranger things in the world than are to be seen between London and Stanes!

"When I was coming away from Blockpoint to return to Boston, several of my acquaintance came to bid me farewell, one of whom was Capt. Thomas Wannerton, who drank to me a pint of *kill devil*, alias rum, at a draft!

"When I returned to Boston, I went to Charlestown with Capt. Jackson; and as we walked out on the back side, we spied a rattlesnake four and a half feet long, and thick as the small part of a man's leg. We saw it seize and swallow a small chicken, such as they would give four pence for in England. In the afternoon, I returned to our ship in the harbor, when I had sight of an Indian pinnace of spruce, with a deck, and trimmed with sails.

"Our master, Capt. Luxon, who had been ashore at Governor's Island, gave me half a score of very fair pippins, which he brought thence; there being not one apple tree or pear tree yet planted in any part of the country, except on that island."

He speaks of an ordinary, at the west end of Boston, where he was provided with a liberal cup of burnt Madeira wine and store plump cake, for his breakfast.

In some places, he says, "the sea rises eighteen feet perpendicular. I had two reasons given for it—one in a sermon—that the spirit of God moving on the water causeth it; and that the spirit of the waters gathered the waters together, as the spirit of Christ gathereth souls."

**Fossil Fishes.**—Previous to 1600, there are perhaps few records of fossil fishes. Fabius Columna and Worm wrote 'De Glossopetris'; in the following century, we had Scheuchzer and Fischer; and, towards its conclusion, the 'Ittiolitologia Vernosa of Volta,' a large folio containing seventy-six plates, which, if not very faithful in execution, showed the interest which was at this time excited; but it was not until so late as 1818 that an enumeration of the fossil species previously known was first attempted by De Blainville in 'Le Nouveau Dictionnaire d'Histoire Naturelle.' Since then, the science has gradually advanced, from its intense interest, and its connexion with the studies of the geologist; and at the commencement of the last year, it assumed a most important station from the researches of a naturalist of Switzerland, and the appearance of the first numbers of this work devoted to this department. The 'Recherches sur les Poissons Fossiles' of Louis Agassiz will undoubtedly mark the commencement of a new era in this science; for, independent of the perspicuity and clearness with which the department itself is

illustrated, the study of existing species, being necessary for a knowledge of those which are extinct, has induced the author to give his views of the science generally, and to propose an arrangement entirely different from those of his predecessors, the characters of which are principally taken from the form and structure of the scales. His orders are as follows:—I. *Placoidians*—so named from the irregularity presented by the solid parts of their covering, composed of masses of enamel. It includes many fossil forms, the sharks and rays.

II. *Oanoidians*—containing varied forms, the saurid fishes, siluri, sturgeons, &c. characterised by scales of an angular form, composed of two substances, plates of horn or bone, placed one upon another, and covered by a thick layer of enamel.

III. *Ctenoidians*—the common character is in the thin plates forming the scales, being pectinated or toothed on their posterior edge, which makes them feel rough to the touch. It contains the chietodons, pleuronectes, the percoid fishes, &c.—IV. *Cyclotidians*—they have the scales formed of simple plates, those of the lateral line with a tube for the transmission of the lubricating mucus. It includes the mullets, calmon, cyprin, &c. The situation in our systems which has been allotted to fishes, has generally been the fourth place, or the lowest rank, in the scale of the vertebrata. They seem to have been more particularly connected with the class which immediately precedes them, by those most extraordinary creatures, long since extinct, but which now occupy so much of the attention of the geologist, the *Ichthyosaurs* or fish-lizards, and which the discovery of new forms leads us to believe were a numerous race, perhaps possessing intermediate ability to exist either in air or water. Fishes are entirely inhabitants of the waters, peopling this immense portion of our globe with their shoals, and serving to keep in check the varied creatures of still lower structure, while they themselves are held in check, and afford sustenance to millions which have been placed in our systems above them. In form they are perhaps the most varied beings in creation, and the most fertile fancy could scarcely depict a shape or appearance to which a resemblance would not be found. They are of "hideous and loathsome bulk," or of the most graceful forms, and gorgeous and resplendent colors; but still among all these we may trace the characteristic shape of a fish, in the head being placed at once upon the shoulders without any length of neck, followed by the body, and finished by the tail; and the parts will be all adapted to the different modes of gaining sustenance, whether it is to be procured by stealth and deceit, or by strength and swiftness."

**NATURAL HISTORY.**—It may be considered as a law, that those fish that swim near the surface of the water have a high standard of respiration, a low degree of muscular irritability, great necessity for oxygen, die soon—almost immediately, when taken out of water, and have flesh prone to rapid decomposition. On the contrary, those fish that live near the bottom of the water have a low standard of respiration, a high degree of muscular irritability, and less necessity for oxygen; they sustain life long after they are taken out of the water, and their flesh remains good for several days. The carp, the tench, the various flat fish, and the eel, are seen gaping and writhing on the stalls of the fishmonger for hours in succession; but no one sees any symptom of motion in the mackerel, the salmon, the trout, or the herring, unless present at the capture. These four last-named, and many others of the same habits, to be eaten in the greatest perfection, should be prepared for table the same day they are caught; but the turbot, delicate as it is, may be kept till the second day with advantage, and even longer without injury; and fishmongers generally are well aware of the circumstance, that fish from deep water have the muscle more dense in structure—in their language, more firm to the touch—that they are of finer flavor, and will keep longer, than fish drawn from shallow water. The law referred to has its origin in the principles of organization; and though it would be difficult for the anatomist to demonstrate those deviations in structure between the trout and tench which give rise to these distinctions and their effects, it is only necessary to make the points of comparison wider to be assured of the fact. Between a fish with a true bony skeleton, the highest in organization among fishes, and the lamprey, the lowest, the differences are most obvious. If we for a moment consider the lamprey, which is the low-

est in organization of the vertebrated animals, with only a rudimentary vertebral column, as the supposed centre of zoological structure, and look from thence up and down the scale of organization, we at the extreme on one side arrive at man, to whom division of his substance would be destruction; but on the other, we come to the polype, the division of which gives rise to new animals, each possessing attributes, not only equal to each other, but equal also to the animal of which they previously formed but a small part."

**THE ORNITHORHYNCHUS PARADOXUS.**—The habits of this extraordinary creature (partaking of the character of a quadruped and a bird) have lately had some new light thrown upon them, by the researches of a British traveller and naturalist.—At a late meeting of the London Zoological Society, a very satisfactory paper was read upon the subject. Mr. G. Bennett, the author of the paper, made the inquiries in the colony of New South Wales, and in the interior of New Holland, at the end of 1832 and commencement of 1833. From one of the burrows inhabited by these creatures, a living female was taken, and placed in a cask, with grass, mud, water, &c.; and in this situation it soon became tranquil, and apparently reconciled to its confinement. Hoping that he had now obtained the means, should his captive prove to have been impregnated, of determining the character of the excluded product, Mr. Bennett set out on his return for Sydney, on the 13th of October, carrying the living *ornithorhynchus* with him in a small box covered with battens, between which only very narrow intervals were left. The next morning, tying a long cord to its leg, he roused it, and placed it on the bank of the river, in order to indulge it with a bathe; and a similar indulgence was granted to it on the second day of its journey. On these occasions it soon found its way into the water, and travelled up the stream, apparently delighting in those places which abounded most in aquatic weeds. When diving in deep and clear water, its motions were distinctly seen: it sank speedily to the bottom, swam there for a short distance, and then rose again to the surface. It appeared, however, to prefer keeping close to the bank, occasionally thrusting its beak into the mud, from whence it evidently procured food; as, on raising the head, after withdrawing the beak, the mandibles were seen in lateral motion, as is usual when the animal masticates. The motions of the mandibles were similar to those of a duck under the same circumstance. After feeding, it would lie sometimes on the grassy bank, and at others partly in and partly out of the water, combing and cleaning its coat with the claws of the hind feet.—This process continued for some time, and greatly improved its sleek and glossy appearance. After its second excursion it was replaced in the box, which was not opened again until the following morning, when it was found to have made its escape. In the examination of another burrow, Mr. Bennett found three young *ornithorhynchus*, which appeared to have, not long previously, been brought forth: they were thinly covered with hair, and measured in length about 1.7-8 inch. No fragments of shells were observable in the burrow, nor any thing that could lead to the supposition of the young having been excluded while yet in the egg. Mr. Bennett then describes their habits in captivity, having succeeded in capturing an old female, and three young ones.

The old woman was in a ragged and wretched condition; little milk could be pressed from her abdominal glands, as might have been expected in the parent of such well-grown young ones. The young were allowed to run about the room; but the old one was so restless, and damaged the walls of the room so much by her attempts at burrowing, that it was found necessary to confine her to the box. During the day she would remain quiet, huddled up with her young ones; but at night she became very restless, and eager to escape. The little ones were frolicsome as puppies and, apparently, as fond of play; and many of their actions were not a little ludicrous. During the day they seemed to prefer a dark corner for repose, and generally resorted to the spot, to which they had been accustomed, although they would change it on a sudden, apparently from mere caprice. They did not appear to like deep, but enjoyed exceedingly a bathe in shallow water, with a turf of grass placed in one corner of the pan; they seldom remained longer than ten or fifteen minutes in the water at one time. Though apparently nocturnal

or, at least, preferring the cool and dusky evening to the glare and heat of noon, their movements in this respect were so irregular, as to furnish no grounds for a definite conclusion. They slept much; and it frequently happened that one slept while the other was running about, and this occurred at almost all periods of the day. They climbed with great readiness to the summit of a book-case, and thus by means of their strong cutaneous muscles, and of their claws, mounting with much expedition to the top. Their food consisted of bread soaked in water, chopped egg, and meat minced very small, and they did not seem to prefer milk to water. One of the young ones died on the 29th of January, 1833, and the other on the 2d of February, having been kept alive in captivity for nearly five weeks. The old one died before.

**THE SUB-MARINE!!**—T. Campbell, in his poetical language, might tell us of a ship, that "She walks the water like a thing of life,"

but in plain prose it can be more distinctly stated of Mr. Dean, that he walks (in) the waters like a thing of life. Our readers are aware that this extraordinary submarine peripatetic, whose piscatorial incubations we formerly noticed when it pleased him to take a promenade at the bottom of the Thames, has since that period been engaged in paying a few visits to the Royal George, where she lies "fifty fathoms deep." One of the guns which he has had raised from the wreck, has, we observe from the newspapers, been sent, like a traitor, to the Tower; but several others have, also, as they say of young ladies at boarding-schools, been well brought up. Two of them are on the pier at Ramsgate. They are of brass, ten feet six inches long, six inches diameter in the bore. Round the breech is the inscription—"Schalch fecit 1742," and an account of the weight, viz 50 cwt. 3 qrs. 24 lb. the one; and 50 cwt. 2 qrs. 17 lb. the other—thus differing in 35 lb. A little above the breech are the royal arms, without supporters; and near the muzzle is a coat of arms, perhaps of the master of the ordnance at the period, or it may be of the founder. Two beautifully modelled dolphins are placed above the trunnions; and the whole workmanship is equal to the finest of the present day. The edges of the ornamental parts are quite sharp; and the only signs of long immersion are that they are green, and have a few pieces of oyster-shells sticking about them. Mr. Powell, of Queen Park, near Margate, has, according to the report, purchased two of the guns to place in his grounds, and given as much as 300*l.* a-piece for them. Assuredly, the enterprising Mr. Dean deserves every encouragement, both private and public.—[London paper.]

**WAR.**—What a picture of horror does the following paragraph present! What blood spilt! What money expended, to enable man to butcher his fellow man! Surely, any price but liberty and honor, should be paid by nations for peace.—[Nat. Intelligencer.]

"Since the year 1,000 there have been 24 different wars between England France, 12 between England and Scotland, 8 between England and Spain, and 7 with other countries—in all 51 wars! There have been six wars within 100 years, viz:—

"1st war, ending 1897, cost 21,500,000*l.* 100,000 slain, 80,000 died of famine.

"2d war, began 1702, cost 43,000,000*l.* Slain not ascertained.

"3d war, began 1739, cost 48,000,000*l.* Slain not ascertained.

"4th war, began 1756, cost 111,000,000*l.* Slain 250,000.

"5th. American war, began 1755, cost 139,000,000*l.* Slain 200,000.

"6th. Last war, began 1793, cost 750,000,000*l.* Slain 2,000,000 amongst all the belligerents.

At the conclusion of the war which ended in 1897, the national debt was 21,500,000*l.* At the conclusion of the last war, in 1815, the national debt amounted to no less than 1,050,000,000*l.*—[Lond. Times.]

**CARTHAGE.**—So literally true is "Delenda est Carthage," that according to the most recent visitor to the site of that once great city, not a vestige of its former greatness remains, while its very name is unknown to the present race of inhabitants.

Plutarch gives a pretty reason for residing in his native place:—"I live in a little city, and I choose to live there, lest it should become still less."—[Langhorne's Plutarch.]

**ORIGINAL LETTER FROM THE EARL OF SURREY TO KING HENRY VIII.**—From the British State papers just published under the King's commission.

"Pleas it Your most noble Grace to understand, that where as I, and others of Your Graces Counsaill here, have divers tymes advertysed Your Grace, how the Iryshman bee confetred to gyddres to destroy your poore subgies; they contynue daily in theyr yll determyned purpose, and aboutes 23 daies past assembled a right great power, after the manner of this land; whereof I, beinge advertysed, assembled the best power I might gather, and the 9th day of this moneth departid towards OConors cuntry, where they were all to gydders. And notwithstanding that I contynued in his said cuntry, unto Tuysday last past, brengnyng all his townes and houses, and destroying a marvelous dele of corne, and also leved siege to his castell, the strongest of all this land, and wanne the same; yit, of all the tyme I contynued there, they wold never fall to no conclusyon of peas, but answerid pleynly to suche, as moovyd to have peas betweene theyme and me, that they wold never fall to peas with Englyssmen, tyll they had utterly destroyed theyme. Whooose wilfulness hath been right chargeable unto the said OConore; for he hath not onely lost his castell, and all his cuntry burned, but also so moche of his corne is destroyed, that his people shall be enforced eyther to forsake the cuntry, or dye for honger this wynter comyng. Undoubtedly, these Iryshmen bee soo soore confetrid to gyddres, that I see no lyklyhod but contynuel warre, which shall be right herde to withstand, without that the Englyshery, and moost especially the countie of Kyldare, shall take summe hurtes, principally for lak of oon good capeteyne to defende the same, when I am besy in othr cuntries. Besechyng Your Grace to advertyse me of your gracious pleasure, whether I shall kepe styll OConors castell forsaide, called Monesteroverys, or jelyver the same to hym agayne. As long as I shall kepe it, he wold be at warre. And if Your Grace entend to conquere this land, it is as necessary for the entre upon Iryshmen cuntries, as Berwyk is in Scotland. I have soo manned and veytalled the said castell, that, with Goddis grace, it shall be out of daungier of Iryshmen, tyll I be advertysed of your gracious pleasure. Signyfying unto Your Grace that when I was in OConors cuntry, the Erll of Ormond made sharpe warre upon Okerrol, and hath doon his part right welc. Besechyng Your Grace to send your gracious letters of thankses unto hym, as wole for his good counsaill yeven to me, at all tymes, as for his paynfull diligent service doon to Your Grace here. Also, I have sver knowledge, by divers espayalles, that OKarwell dooth assemble a mouche gretter power, then he did this last tyme; contending to make a great invasion upon Your Graces poore subgies. For the repressyng of whoos malyce, I assay all the freendes I can, oswele English as Irysh; and shall do my best, not oonley to let hym to invade Your Graces subgies, but also to doo the moost hurtes I can to hym, and his partetakers. Also, oon Richard Pepyr, of Calays, hath of late robbed and despoyled twoo Brytton shippis, upon the see, and hath brought with hym oon of their ballyngers. He had in his company aboutes 20 persons, and they bee in preson at Corke. Besechyng Your Grace, that I may be advertysed of your gracious pleasure, whate shall bee done with hym and theyme. If Your Grace wold have theyme put to execusyon, Your Grace muste send me a comyssion soo to doo; for I haue noon auctoritie otherwise to put theym to deth, and the long keepyng of theme wold bee chargeable to Your Grace. I can advertyse Your Grace of noo moo of their names, but onely Rychard Pepyr; wherfor, yf Your Grace wol have theym put to deth, there must be lefte a blanke in the comysion, for their names to bee put in when I shall know theym. Also, I besече Your Grace, that there may bee joyned with me in the comyssion, Patrike Brynmyngham, Chief Justice of your Benche, Rychard Delahayde, Chief Justice of the Canon Place, James Cantwell, Arthur Mygyn, Cormok McRoryk, Bacheters of Lawe. Also yf it myght stand with your gracious pleasure to send me a comyssion, with auctoryte to put to deth all rovers of the see, that shuld fortune to bee takyn in this land, it is thought by Your Gracis Counsaill here, it shuld doo moche good, for this land is the very land of refuge that Englysh pyratres resort moost unto. And I, having the

said comyssion, Your Grace shuld see at me charge in keepyng of theyme, unto a comyssion were sent fro Your Grace to the out of England. Besechyng Your Grace, if it shall lyke Your Highness to sende me any of the said comyssions, to geve me auctorytie to pardon suche of theyme, as shall be thought by me, and Your Gracis Counsaill here, the feest offenders, and moost convenyent to bee pardoned; or els, yf there were never soo many taken, all mast dye, which I feare might be rekensyd to bee too soore. Most humble besechyng Your Grace, that I may brevely know your gracious pleasure in the premissis, and I shall dayly pray for the long prosperous contynewance of your most royal astate. Wryten in Your Graces Castell of Dublyn, the 29 day of July [1581]. Your most humble subject,

"(Signed) T. Surrey."

"(Superscribed)  
To the Kynges Most Noble Grace."

**PARISIAN STATISTICS.**—During the last year there were born in Paris 29,130 children, namely—14,901 males, and 14,229 females. Of these 19,145 were legitimate; 18,685 of them being born in private houses, and 460 in the hospitals or almshouses; 9985 were illegitimate, 5473 of whom were born in private houses, and 4512 in the hospitals. Of the natural children 1170 were acknowledged by their parents. The deaths amounted to 24,177 namely—12,004 males, and 12,173 females. Of these 15,340 died in their own houses, and 8,837 in the hospitals. The number of births exceeded that of the deaths by 4953. The marriages were 8088. In 1833 there were 27,460 births; 25,096 deaths, 7038 marriages.

**A PARTICULAR MISTRESS.**—A Provincial paper contains the following advertisement for a housemaid:—"A young French girl wanted, as housemaid; she must rise early in the morning, light the drawing-room fire (but not clean the grate;) she must never wear curl papers, and never presume to give her advice or suggest any thing."

**To the Editor of the National Gazette:**

The following lines by the Hon. Mr. Wilde, of Georgia, were probably not designed for publication; but the feeling and taste which pervade them can scarcely fail to be admired, and permission has therefore been obtained of the lady to whom they were inclosed, to hand them over to you.

*Ship Westminster at sea off the heights of Newmarket, June 1, 1834.*

Farewell! my more than father land!  
Home of my heart and friends adieu!  
Lingering beside some foreign strand,  
How oft shall I remember you!  
How often o'er the waters blue,  
Send back a sigh to those I leave,  
The loving and beloved few,  
Who grieve for me;—for whom I grieve.  
We part!—no matter how we part,  
There are some thoughts, we utter not,  
Deep treasured in our inmost heart,  
Never revealed, and ne'er forgot!  
Why murmur at the common lot?  
We part!—I speak not of the pain,  
But when shall I, each lovely spot,  
And each loved face, behold again?  
It must be months,—it may be years,  
It may—but no!—I will not fill  
Fond hearts with gloom,—fond eyes with tears,  
"Curious to shape uncertain ill."  
Though humble,—few and far,—yet still,  
Those hearts and eyes are ever dear;  
There's in the love no time can kill,  
The truth no chance nor change can sever!  
All I have seen,—and all I see,  
Only endears them more and more;  
Friends cool—hopes fade—and hours flee,  
Affection lives when all is o'er!  
Farewell my more than native shore!  
I do not seek or hope to find,  
Roam where I will, what I deplore  
To leave with them and thee behind!

[FOR THE NEW-YORK AMERICAN.]

**SONG.—Hours of absence.**

Round our lone and ancient dwelling,  
(Like the sighs of friends away)  
Mournfully the breeze is swelling,  
And the billows wildly play.  
There when shades of eve are o'er the,  
And the taper's cheerful light  
Shines on all (but one) before me,  
Memory pictures scenes more bright.  
And in vision I am wand'ring  
By a cool embower'd stream,  
On thy parting accents pond'ring,  
Life! would thou wert all a dream!!  
Can it be? that voice of sweetness  
I must sigh to hear in vain?  
Fly oh! thou—whilst love's own sweetness,  
Still I hear those songs again.

ELIZ.

RAILROAD JOURNAL AND ADVOCATE OF  
INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of EIGHT pages, devoted mainly to the subject of internal improvements, in all its various modes and forms.

Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, in ADVANCE. Previous volumes same price; full set of four volumes, \$12.

## RAILROAD AND CANAL MAP.

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$5.

MECHANICS' MAGAZINE, AND REGISTER OF  
INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 384 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, in ADVANCE. Previous volumes \$2.50 each.

## THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to *persuade* APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY-THREE for \$10. D. K. M.

## NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given—Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

QUARTERLY JOURNAL OF AGRICULTURE,  
MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$5, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 320 pages.

These works may all, or either of them, be had of S. Hydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fensenden, Philadelphia; or of the Proprietor and Publisher,

D. K. MINOR,  
35 Wall street, New-York.

PATERSON AND NEW YORK RAILROAD LINE.  
SUMMER ARRANGEMENT FOR 1835.

Passengers will leave Pater- New York by Jersey City  
son at Ferry at

6 1/2 o'clock, A. M. by Steam	5 1/2 o'clock, A. M. by Horses
10 1/2 " " " " " " " "	8 " " " " " " " "

4 1/2 " " " " " " " "	3 " " " P. M. Horses
6 1/2 " " " " " " " "	5 1/2 " " " " " " " "

## ON SUNDAYS.

Pater-son at 6 1/2 o'clock, A. M. by Steam,

2 1/2 " " " " " " " " " " " "

5 " " " " " " " " " " " "

New York at 8 o'clock, A. M. by Steam,

5 1/2 " " " " " " " " " " " "

8 " " " " " " " " " " " "

11 1/2 " " " " " " " " " " " "

2 1/2 " " " " " " " " " " " "

Ticket Office in Pater-son, corner of Congress and Main streets, opposite "Congress House."

Ticket Office in New York, 76 Courtland st.

Passengers with Tickets will have a preference in seats.

Fare from Jersey City, 50 Cents.

Transportation Cars will also ply three times a day each way.

As the Ferry boats do not leave New York precisely at the above times, it is recommended to passengers to procure their tickets and to be at the Ferry a few minutes before the stated hours of departure.

PATRICK COUGHLIN, Agent

in New York.

1837

## PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thorough printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-15

## THE CHICAGO AMERICAN.

ON Saturday, June 9th, was published the first number (to be continued weekly) of a newspaper, under the above title, in the thriving village of Chicago, Illinois. It is printed on a handsome large sheet, and from type entirely new, and leased to subscribers at the low price of \$2 50 per annum, if paid in advance, and \$3 00 at the end of six months.

Merchants in New York, and others, will find this paper a favorable medium for advertising, as its circulation is expected to be extensive in Chicago, and the far West generally.

PUBLISHERS generally will do well to advertise in its columns; a fair and almost certain opportunity is open for the circulation of books, and especially periodicals, in a district where hitherto they have been unknown.

LAND OWNERS and Agents will find it their interest to consult its columns, and advertise also, as every progress made in promoting internal improvements that will benefit the western trade, will be faithfully recorded in its columns.

Subscriptions received by the Agents, T. & C. WOOD, Stationers, 35 Wall street, where a specimen number may be seen, and advertisements received and forwarded free of expense. Je.19.

## TO TUNNEL MINERS, DRILLERS, &amp;c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred), 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

## JOHN BUTTER, Contractor.

37 The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-15

## RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and knees, and every other description of castings required for railroads. R-15 Feb 14

## STEPHENSON,

Builder of a superior style of Passenger Cars for Railroads.

No. 264 Elizabeth street, near Bloeker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J36 15

## NOTICE TO MANUFACTURERS.

SIMON FAIRMAN, of the village of Lansing,burgh, in the county of Rensselaer, and state of New-York, has invented and put in operation a Machine for making Wrought Nails with square points. This machine will make about sixty 6d nails, and about forty 10d nails in a minute, and in the same proportion larger sizes, even to spikes for ships. The nail is hammered and comes from the machine completely heated to redness, that its capacity for being clenched is good and sure. One horse power is sufficient to drive one machine, and may easily be applied where such power for driving machinery is in operation. Said Fairman will make, vend and warrant machines as above, to any persons who may apply for them as soon as they may be made, and on the most reasonable terms. He also desires to sell one half of his patent right for the use of said machines throughout the United States. Any person desiring farther information, or to purchase, will please to call at the machine shop of Mr. John Humphrey, in the village of Lansingburgh. August 15, 1835. A29 MF & Rtf

PATENT RAILROAD, SHIP AND BOAT  
SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale every extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersunk heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named Factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

Troy, N. Y. July, 1835. HENRY BURDEN, Agent.

Spikes are kept for sale, at factory prices, by J. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 223 Water street, New-York; A. M. Jones, Philadelphia; T. Janviers, Baltimore; Degrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes.

H. BURDEN.

RAILROAD CAR WHEELS AND BOXES,  
AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, CAR SPRINGS.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

PATENT HAMMERED SHIP, BOAT, AND  
RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory.

Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water.

Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sep.12-17

## RAILWAY IRON.

95 tons of 1 inch by 1/2 inch,	Flat Bars in lengths of
300 do. 1 1/2 do. do.	14 to 18 feet, counter sunk
40 do. 1 3/4 do. do.	holes, ends cut at an angle
800 do. 2 do. do.	of 45 degrees, with spli-
800 do. 2 1/2 do. do.	cing plates and nails to
	soon expected.

250 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 32, and 26 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2 1/2, 3, 3 1/2, 3 3/4, and 4 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment. A. & G. BALSTON.

9 South Front street, Philadelphia. Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. dilmecov

## SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane. J21 6t

SURVEYING AND ENGINEERING  
INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG,

Mathematical Instrument Maker,

No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested. Baltimore, 1835.

In reply to his inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES F. STABLE, Supt of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1835. Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

German town, February, 1835. For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad. m ly  
German. and Norrist. Railroad

## AMERICAN RAILROAD JOURNAL.

NEW-YORK, JULY 4, 1835.

THIS number completes the first half of volume FOUR of the Railroad Journal. The Journal was commenced with little expectation of profit, yet not without confidence that the receipts from subscriptions and sales would meet its expenses for paper, engraving, and printing. Our expectations have not been realized, and, therefore, retrenchment must become the order of the day; present engagements, however, will be fulfilled, and the Journal, containing 16 pages each number, will be sent to all who are now subscribers until the close of the volume, or 1st January next; but after that date, and to all new subscribers from the present time, the Railroad Journal will contain eight pages only to each number. The terms, however, will not be reduced, as the expenses of the work must be paid, hereafter, by those for whom it is published, or it will not be continued as a distinct work. I profess to be liberal, and desire to be of service to others, yet I cannot afford to work for nothing, as its editor, and fall in debt at the close of the year for the privilege. If the work has been of any service to the cause to which it has been devoted, then should it be sustained, if not, then it should, and shall, be discontinued, or devoted to other subjects—reprinting of novels for instance, or the like works of utility! which seldom languish for want of subscribers.

Subscribers, who are now indebted for the Journal, will greatly oblige us by remitting the amount due, or we shall certainly oblige them—by discontinuing to send it to them,—as a work which is not worth paying for, in the course of the year, cannot be worth having.

☞ If this should meet the eye of any who desire to aid in sustaining the work, they will learn from it, that for a ten dollar note, current money, they can obtain the work entire, from commencement to this date, three and a half years, stitched in half yearly parts, of about 400 pages each, which can be sent by mail to any part of the United States.

☞ If two hundred complete sets of the work now on hand could find sale immediately, it would place the balance on the other side of the ledger. Would it not be for the interest of railroad companies, throughout the United States, to purchase each four or five sets of the Journal, rather than to have it discontinued? Who would be the greatest gainer, those so deeply interested in knowing all the improvements connected with railroads, or the proprietor, who has published it near four years without a penny for his personal services?

This is the last appeal in its behalf; and should it not produce the desired and necessary result, the Railroad Journal will probably be merged in the Mechanics' Magazine after the close of the current volume; or be discontinued entirely.

AUGUSTA AND ATHENS (Geo.) RAILROAD.—We continue in this number the Report of A. A. DEXTER, Esq., which was commenced in our last, on his survey of the route for a Railroad from Augusta to Athens, Georgia. This will be, in truth, a continuation of the Charleston and Augusta road which is now in successful operation; and another important link in the railroad which will surely be extended through Alabama and Mississippi to the Father of Rivers, and probably to the Gulf of Mexico.

We are much obliged to Mr. Dexter for his politeness in forwarding drawings also with the report, as it is of importance, as we believe, to Engineers, to know the manner in which the different roads are constructed; and we like to have the "Journal" made the medium of that communication. For its long delay after it came to hand, he will please accept as an apology—"mislaid amongst other documents on the Editor's table."

EXPERIMENTS on the Strength and other Properties of Malleable Iron, by PETER BARLOW, F. R. S., London.—We commence, in this number, the publication of this work, and shall publish the remainder of it in the two succeeding numbers. The information contained in it will be found highly valuable to those interested in Railroads.

Mr. Barlow, it will be seen, gives the preference to the parallel rail, and says, that on the Liverpool and Manchester Railroad they replace the fish-belly with the parallel rail, whenever it is necessary to take up a defective rail.

☞ PIRACY.—The Gallatin (Miss.) Democrat has the following important intelligence:

ADDITION TO A NAME.—We learn that the paper to be published at Madisonville, in this State, called the Southern Transcript, is to have an additional name appended to it, and to be called The Southern Transcript and "Railroad Journal."

Now look at the title of this Journal, and then tell us if they have not pirates as well in Mississippi as on the "high seas," or in New-Jersey. But, never mind—there is work enough for more of the same name, if they will only strive to advance the cause they profess to advocate. They will find, however—as we have—that the name will not ensure a patronage equal to its expenses, if they give the necessary engravings and illustrations.

We are gratified to learn that Captain McNeil is appointed Chief Engineer of the Long Island Railroad.

## ESTIMATE.

256,765 c. yds. of ex. and emb't. at 13 c....	\$31,051 80
7 miles construction ironed complete at \$4,131 80 per mile.....	28,943 60
5 miles of construction at \$3,433 30.....	17,266 50
12 miles grubbing and clearing at \$150.....	1,800 00
Culverts and road bridges.....	2,908 00
2 turnouts and houses for attendants.....	2,300 00
	84,061 40
Add 10 per cent.....	8,406 14
Amount.....	\$92,467 54

## SECTION NO. V.

This section, 12 miles in length, terminates at 62 miles from Augusta, and 4 miles east of Crawfordville. The average depth of excavation and embankment is 5 33-100. The steepest grade is 1 in 200. Maximum height of embankment, 31 feet, and of excavation, for a short distance, 16 feet. The pine wooded region in this section is lost in a mixed growth, in which oak and chestnut predominate. In these 12 miles there are but 5 curves, of which the shortest radius is 3000 feet. The soil in the excavations will form a good foundation for plan No. 1.

## ESTIMATE.

291,805 c. yds. of ex. and emb't. at 13 c....	\$37,934 85
7 miles construction complete at \$4,131 80.....	28,943 60
5 miles do. do. at \$3,433 30.....	17,166 00

	90,744 85
Add 10 per cent.....	9,074 43
Amount.....	\$99,818 67

## SECTION NO. VI.

Beginning 4 miles east, and extending 8 miles beyond Crawfordville, passing directly through that village, being 12 miles.

This section is the most favorable of any on the whole route, as regards the depth of cutting, and quantity of excavation and embankment. The maximum height of the latter being only 12 feet, and the former but 10 feet. The steepest graduation need not exceed 1 in 200, although 1 in 178 is adopted for a short plane on the profile. There are six curves on the line of location, all of easy radii, the shortest 3000 feet.

The soil is a stiff, red clay, which will afford a very solid foundation. The line passes through a highly cultivated and productive cotton region. The timber (oak and chestnut) is generally cleared off—however, it is probable that enough may be obtained, in convenient vicinity to the line, for the purposes of construction.

## ESTIMATE.

175,043 c. yds. of ex. and emb't. at 10 c....	\$17,504 30
6 miles construction at \$4,131 80.....	24,808 80
6 do. do. at \$3,433 30.....	20,599 80
3 turnouts and water stations and extra fixtures at Crawfordville.....	3,600 00
2 houses for attendants.....	1,000 00
Grubbing and clearing.....	1,900 00
	68,718 30
Add 10 per cent.....	6,871 23
Amount.....	\$75,589 53

## SECTION NO. VII.

This section is 13 miles in length, and ends at 87 miles from Augusta, about 1 mile west of Penn's store. The profile is not unfavorable, although the expense of graduation considerably exceeds that of the preceding section. The curvature and planes of profile as favorable as heretofore. At 4 miles from the beginning of this section, the branch line passing through Greensboro commences.

The excavation will be in a hard clay, and rock may be obtained in the vicinity of the line.

## ESTIMATE.

## SECTION NO. VIII.

This section is 15 miles in length, ending at 102 miles from Augusta. The course is very circuitous, necessarily, in pursuing the ridge round the head of Big creek, the valley of which is so deep and broken as to be utterly impassable.

The line makes nearly a right angle in its direction at the Hon. W. H. Crawford's, turning in a radius of 3500 feet. The greatest depth of cutting which will be requisite on this section, will be about 17 feet, and 23 feet will be the maximum height of embankment.

A plane, rising 1 in 176, or 35 feet in a mile, will be the steepest rate of inclination.

## ESTIMATE.

Amount.....	\$110,664 51

## SECTION NO. IX.

This section, part of which is yet unlocated on the maps, extends from near Gen. Pope's, to Athens, a distance of 12 miles, ending at 114 miles from Augusta. A plane of 1 in 178 will be necessary in rising out of the valley of Shasi creek, after which, by crossing into the head of Trail creek, an easy descent may be obtained along the bed of that stream into the valley of the Oconee, striking the same above the present bridge at Athens. Rising from the river into town, the ground is favorable for an inclined plane.

" 2 opposite Warrenton.....	3,500 00
" 3 at Crawfordville.....	5,000 00
" 4 at Carlton's.....	2,000 00
" 5 opposite Lexington.....	3,500 00
" 6 at Athens.....	7,000 00
Stationary engine and fixtures.....	12,000 00
	40,000 00
Amount.....	\$1,092,047 99

We omit the details of the Sections and give the GRAND SUMMARY.

Cost of railroad from Augusta to Athens.....	\$1,092,047 99
Cost of western branch lines to Madison and Eatonton.....	513,744 71

Total, exclusive of machinery.....\$1,605,792 70

The above amount may thus be divided:

Cost of the main Union track, from Augusta to Carlton's, 78 miles.....	\$763,996 12
Cost of the branch from Carlton's to Athens, 36 miles.....	328,051 87
Cost of the branch from Carlton's to Tompkins's, 25 miles.....	325,219 10
Cost of the branch to Madison, 12 1/2 miles.....	114,353 03
Cost of the branch to Eatonton, 7 1/2 miles.....	70,142 58
	\$1,605,792 70

Add for machinery—

10 large English freight engines, at an average of \$6,000.....	\$60,000 00
250 freight cars, at \$300.....	75,000 00
6 English passenger engines, at \$5,500..	33,000 00
18 carriages, at \$600.....	10,800 00
Tools and fitting up workshops, and duplicates of machinery.....	25,000 00

Grand total amount.....\$1,810,592 70

It has been my desire, in making the foregoing estimates, to put every thing at its highest valuation, that no disappointment may hereafter ensue, from an excess in the expenditure over the contemplated cost. I have endeavored to guard against a dangerous practice, too often pursued, of misleading the public mind in the estimates; the consequence of framing the same rather in the spirit of sanguine expectation, than from the results of experience, and the dictates of impartial judgment.

While I am sensible that the cost will, in all probability, fall within the amount in many items of the estimate, yet, as the contingencies are numerous on a work of this kind, and unexpected difficulties may occur, I do not think that I have exercised more than a proper caution in this respect.

It scarcely enters into the province of the engineer to furnish statements regarding the revenue and statistics of a work of this nature. The direction have probably much better sources of information than myself, for forming a correct judgment on this important subject. However, as the estimate of the income involves considerations arising from the expense of transportation, as well as the wear and tear of machinery and repairs of the road, an estimate of this nature from the engineer may be of some service in determining the probable net revenue of the work.

As a portion of the cotton, which now finds a market in Macon, will unquestionably take the route of the railroad to Augusta, we think we may safely calculate on taking from Athens, Madison, Eatonton, and the intervening points, Greensboro, Crawfordville, Lexington, Warrenton, &c.: 150,000 bales, at \$1.....\$150,000 00

Transportation of up freight, equal to the above, and 33 1/3 per cent. over..... 200,000 00

Passengers, equal to 100 per diem, on all the routes taken, 110 miles, including way passengers..... 200,750 00

Transportation of mails, and various downward freight, other than cotton.. 25,000 00

Amount.....\$575,750 00

To do the business of the road, about 16 engines would be necessary, of which 10 would be constantly in use. The following arrangement might be adopted with the passenger engine: One to leave Athens, and one to leave Madison at about the same time in the morning. The engine with the passengers from Madison would proceed to Eatonton in time to receive the great western mail and passengers, which would be conveyed by the same engine through

Greensboro to Carlton's, a distance by this route of 54 miles. Here this locomotive would meet the engine from Athens, which would have travelled 36 miles.

The train of cars from the north and west would now be united in one, and taken by a third engine to Augusta.\*

The engines from the west and Athens would then remain at this station until the arrival of the Augusta locomotive, when that from Athens would proceed to Madison by way of Eatonton, leaving at the latter place the western mail and passengers, and that from Madison would go on to Athens.

Thus the daily service of each engine would not exceed 90 miles; those on the Athens and western branch line would run 90 miles; that on the main line to Augusta, would travel 78 miles.

In this distribution of the labor of the locomotives, the amount performed by each would not exceed that which it would be capable of accomplishing with ease and certainty. This would require, therefore, the constant use of four locomotives, two on the union line, and two on the several branches. To provide six English passenger engines would be an abundance, allowing for accidents, and occasional repairs of those in use.

The engines for freight should be made of great power, capable of carrying from 500 to 1000 bales of cotton.

On a road built on the plan of the Georgia railway, with permanent embankments, a rate of 10 or 12 miles an hour, with the freight engines, may be allowed. As stoppages, taking in fuel and water, delivering and receiving freight, &c., will occupy considerable time, and as steep rises at the head of Butler's creek and on the branch lines, may cause some detention, the freight engines may not perform the trip in the winter season in less than 1½ days.

One engine with freight might leave Madison, Eatonton and Athens every other day, and meet at Carlton's, where a daily departure would be made for Augusta, and likewise from Augusta for Carlton's; this arrangement would require the constant employment of 5 engines, that is, 2 on the main and 3 on the branch tracks. But as, at certain seasons, the exigencies of business might require a greater number of engines, so as to leave each of the terminating points daily, and as provision ought to be made for every extent of business, as well as against every contingency of accident, &c., we will assume that 10 freight engines may be necessary. There will be, by the arrangement we have mentioned, 4 passenger and 5 freight engines in daily use.

Allowing for all wear and tear of engines and cars, expense of oil, fuel, water stations, attendants, engineers, &c., we may put cost of running each engine at \$16 per diem.

27 supervisors of road and keepers of turn-outs.....	\$52,560 00
Expense of hands at the depositories and repairs of the road, &c.....	9,720 00

Deduct from.....	575,750 00
Leaves.....	\$462,724 00

As a net amount of income, equal to 25 per cent. on the capital invested.

\* Passengers for Augusta might remain at Tompkins to breakfast, while the engine went to and returned from Eatonton.

I consider the above result entirely derivable from the present work, as contemplated, without taking into view any additional revenue from those extensions of the road into Tennessee, and west from Madison or Eatonton, which will be the almost inevitable consequence of the completion of the Georgia railroad. The receipts of the South Carolina railroad, in a short period, will probably average 12 or 1500 dollars per diem; as upwards of 1000 dollars have lately been frequently taken in the day, although the amount of cotton sent upon the road, up to this time, does not exceed 8000 bales, as the high river during the whole of this season, and long drayage, and heavy tolls across the Savannah bridge, have prevented any cotton of consequence being sent by way of the railroad from Augusta to Charleston.

The fact, that it costs the planter at Madison, Eatonton and Athens about 3 dollars per bale, nearly one tenth part of the value of his crop, to take it to Augusta, places the certainty of the transportation of this grand staple on the railroad beyond a question. The same fact applies also to up freight, which costs in wagons about \$1½ per 100 wt. per 100 miles.

The circumstance, indeed, that there is no competition of any nature to be feared in the operations of this railroad; that not even a good turnpike exists to offer a feeble contention with it; that the roads, at the very season when the crops are ready for transportation to market, are almost impassable—presents a combination of facts, which speaks in the most encouraging language to the promoters of this enterprise to persevere in their undertaking.

But it is not to the amount of the yearly dividends on the capital invested, however flattering the prospect, that the planter is to look for his chief reward from the work. It is from the increase in the worth of his real estate, in the doubled, trebled, and quadrupled value of which, he will find himself suddenly invested with fortune, as if by magical influence. The tide of emigration will be arrested, as it sweeps over the country in its westward course, and the people learn to be satisfied in the enjoyment of a new prosperity, and the attendant comforts, and refinements secured to them in their "father land."

If we were asked to define one of the chief sources of the wealth and prosperity of the people of America, we should say it was the increase in the value of real estate. And wherever we see the greatest industry and enterprise among the people, evidencing itself in the improvement of property, and in the establishing of those grand channels of communication, which are the very arteries of the agricultural, as well as of the commercial system, we plainly perceive the stronger indications of solid wealth and growing prosperity.

It is perhaps a fortunate circumstance that the south has not hitherto embarked more extensively in those great schemes of internal improvement, in the accomplishment of which, northern capital and industry, for many years past, have been so forcibly directed.

Treading upon the footsteps of our neighbor, we may avoid her blunders, and take warning from the beacons of misdirected enterprise.

As I have thus ventured to stray from the subject matter of my report, I will take occasion to offer a few additional remarks, in which I hope your patience will indulge me.

Turning our eyes upon the north, we behold a country, naturally rugged and barren

in comparison with our own, highly cultivated, wealthy, and populous, filled with the spirit of active industry; the restless and unsatisfied march of improvement manifesting itself in every department of the useful arts; an immense tide of commerce pouring itself through a thousand fruitful channels of inland transportation, wherever it flows, like the floods of a mighty river, leaving a deposit of wealth upon its way.

It has been urged that there exists in the domestic institutions of the south an opposing evil, which prevents the action of this spirit, and deprives us of the benefits which result from its exercise. But where is the foundation for the assertion?

There is in the Agricultural interest of the south a real and substantial wealth, which, being widely diffused, and generally enjoyed, is the source of security and ease among the people, rendering them less disposed to speculative enterprises, which require the withdrawing of capital from an always safe and profitable investment.

That the ability to execute exists, and that there is a good sense among the people which will point out to them the vast and inestimable advantages, to themselves, and to the country, which will reward their efforts, cannot be questioned. Let them once awake to a full sense of the importance and value of these undertakings—let them take the necessary measures to empower their construction, embarking with zeal in their prosecution, and foreign capitalists, lured by the valuable privileges of the charters, and the rich harvest of revenue to be secured, will gladly lend a helping hand in furnishing the necessary means for their accomplishment.

Our great staple of production is, of all others, the best calculated, from its portability, and value, for railroad transportation. No doubt can be entertained, at this time, of the fact, that railroads may be constructed at the south, owing to the mildness of the climate, the clearness of the land, the abundance of materials, and the peculiar labor, at a cost, vastly less than is necessary at the north.

Complete this Union Georgia railroad, and we shall have 296 miles of railroad accomplished in South Carolina and Georgia, at a cost of \$2,700,000—less than one half the cost of the 35 miles of the Liverpool and Manchester railway, about double the cost of 16 miles of the Albany and Schenectady road, and not more than that of the 14 miles of the Chesapeake and Delaware canal.

The works which we have named are of the most expensive class—and, on the same plan of graduation, would doubtless have cost nearly as much in a southern climate. But at the same time we contend that, weighing the results produced, will the capital expended, the balance is vastly in favor of the south.

In no works of the north, nor in any that we are aware of in Europe, will the same capital afford the amount of nett revenue, which may be obtained when judiciously expended in these southern enterprises.

Not only may an immediate and large revenue be expected, but, extending over so wide a section of territory, these works embrace the prospect of a vast addition to their income, from an improvement in the agricultural condition of the country through which they pass, and from the ultimate extensions which will necessarily ensue.

That a communication between Charleston and the valley of the Mississippi, by means of an extension of the Athens branch of the Georgia road, will be accomplished, is as certain as that the Georgia railroad will be executed. It needs no extraordinary

foresight to perceive the splendid results which will attend the accomplishment of this great work.

It will not only add an immense value to the stock of the original roads, but will be productive of incalculable benefit to the whole country.

The productions of the fertile west will find a profitable market in the south Atlantic states, flooding the land with almost every article of domestic consumption, for not only will her overflowing granaries pour their rich stores into the cotton growing sections of the south, but manufactories and every species of domestic industry, encouraged by the facility of intercourse with the seaboard, by the abundance of water power, and the cheapness of labor, will spring up in the west, as well as in every section of the south where natural advantages are enjoyed.

But, not only from a reciprocity of commercial intercourse, will the south and west derive a mutual benefit, but the over-production will find a ready market for exportation in Charleston, which, from her commanding position and peculiar advantages, should she still continue true to herself, and actuated by the same bold spirit of enterprise which has lately given a new impulse to her prosperity, must eventually become the great mart of southern Atlantic commerce. The lines of railroad soon to be in course of construction, in addition to those already completed, embrace two-thirds of the whole distance between the Mississippi and the Atlantic.

The eye of the patriot cannot but dwell with satisfaction on the prospect presented in the accomplishment of this grand chain of commercial intercourse.

Intersecting the great valley of the Mississippi below the junction of all its important tributaries, arresting the rich freights of the Tennessee on their great northern tour, embracing in multifarious extensions the interest of the whole interior, it is almost beyond the imperfect efforts of the imagination, to perceive the full extent of the results of this great work, which is to revolutionize the transportation, and affect more or less the whole agricultural and commercial interest of the west.

An amount of \$3,000,000, in addition to the capital already embarked in these enterprises, will probably accomplish this grand object, and secure a trade to the south Atlantic seaboard infinitely more valuable than that for which those great rival works, the Pennsylvania canal, the Baltimore and Ohio railroad, and the Chesapeake and Ohio canal, with an aggregate capital of \$50,000,000, are now contending.

With these prospects, and these facts before them, is it possible that this feasible undertaking, for the accomplishment of which such comparatively insignificant means are necessary, can long appeal, in vain, to an enterprising people, for the amount of capital necessary to carry it into execution?

There can be but one reply to this interrogatory, even were we ever so doubtful of the alacrity of those, who have so large an interest at stake, to embark in it. It is known that many English, and other foreign capitalists, are now turning their attention to the south, as embracing from the solid and substantial basis of its agricultural wealth, and from the wide and virgin field for speculative enterprise which it opens before them, advantages for the investment of capital which are entirely unknown to any other country.

In conclusion, we have our prosperity in our own hands, and with that wide extent of territory, which is one of the greatest

blessings which characterizes our country, united with an enterprising spirit, establishing the means of ready intercommunication and commercial exchanges,—diffusing the lights of education among the people,—the south may, in a few years, secure in her own enviable and increasing prosperity, smile at the disappointed predictions—alike, of mistaken friends and fanatical revilers.

With my best wishes, gentlemen, for the complete success of the noble and patriotic enterprise in which you have embarked with so determined a spirit, and with such flattering prospects before you,

I have the honor to be,

With the highest respect, &c.

ANDREW ALFRED DEXTER,  
Civil Engineer.

Augusta, May 29, 1834.

*Statement of the party employed under the Chief Engineer, in the duties of the survey.*

George B. Lithgoe,\* of South Carolina, assistant engineer, head of party No. 1.

D. W. Johnson and G. V. B. Williams, of South Carolina, rodmen; James W. Harris, of North Carolina, topographical delineator.

Two chainmen and one axeman.

John L. Cole,† of Charleston, S. C., assistant engineer, head of party No. 2.

S. F. A. McDowell, of Columbia, S. C., rodman; Wm. Henry Austin, of Missouri, surveyor and topographical delineator.

Two chainmen and one axeman.

*Remarks.*—The time occupied in the field labors was three months—from November to February—the season was remarkably inclement and unfavorable. Difficulties peculiar to the country rendered the task unusually burdensome and disagreeable. The heavy rains and snows made the roads nearly impassable, so that it was with difficulty a six horse team could convey our baggage wagon, containing the tents, camp equipage, luggage, provisions, instruments, &c., of the two parties from place to place. During a week, when incessant rains confined the party to the tents, they were greatly indebted to the kindness of Mr. Henry Pope, of Oglethorpe, for many polite attentions, for which, at the request and in the name of the whole party, I tender him their grateful acknowledgments.

To the untiring industry and perseverance of Messrs. Cole and Lithgoe, and the gentlemen assisting them, I am indebted for the rapid prosecution and timely completion of the survey, embracing 170 lineal miles, and I should do injustice to my feelings, were I to neglect this opportunity of bearing testimony to their ability and professional merit. In protracting the maps and profiles, making out the estimates, &c., which occupied between three and four months, I was assisted by Messrs. Wm. Henry Austin and James W. Harris, and occasionally by Mr. A. Mezzyk, McCaine.

\* Since appointed superintending engineer of the western division of the South Carolina railroad.

† Since appointed superintending engineer of the eastern division of the South Carolina railroad.

*Experiments on the Transverse Strength and other Properties of Malleable Iron, with Reference to its Uses for Railway Bars.* By PETER BARLOW, F. R. S., Cor. Mem. Inst. of France; of the Imp. and Roy. Acad. of Petersburg and Brussels, etc.

In order to render some remarks and observations in the following pages intelligible to the general reader, it will be necessary to state a few particulars relative to the circumstances which gave rise to the experiments, and to the appearance of them in their present form.

The Board of Directors of the London and Birmingham Railway Company, desirous of carrying on the great work in which they are engaged on the most scientific principles; and, if possible, to avoid the enormous cost of repairs which has attended some large works of a similar description, offered, by public advertisement, a prize of one hundred guineas "for the most improved construction of railway bars, chairs, and pedestals, and for the best manner of affixing and connecting the rail, chair, and block, to each other, so as to

avoid the defects which are felt more or less on all railways hitherto constructed;" stating, that their object was to obtain, with reference to the great momentum of the masses to be moved by locomotive steam engines on the railway,

1. "The strongest and most economical form of rail.

2. "The best construction of chair.

3. "The best mode of connecting the rail and chair; and also the latter to the stone blocks or wooden sleepers. And that the railway bars were not to weigh less than fifty pounds per single lineal yard."

In consequence of this advertisement, a number of plans, models, and descriptions were deposited with the company within the time limited by the advertisement; and others were received afterwards, which, although not entitled to the prize, were still eligible to be considered with reference to their adoption for trial. On the 24th of December last, a resolution was passed at a meeting of the Directors, appointing J. U. Rastrick, Esq., of Birmingham, N. Wood, Esq., of Newcastle, Civil Engineers, and myself, to examine and report upon the same, with a view to awarding the prize; and, at the same time, we were requested to recommend to the Directors such plans, whether entitled to the prize or not, as might be considered deserving of a trial. We met accordingly in London; and, after a long and careful examination of the several plans, drawings, and written descriptions, recommended those we thought entitled to the prize, which was awarded by the Directors accordingly. But that part of our instructions which required us to recommend one or more rails for trial, we were unable to fulfil to our satisfaction, principally for want of data to determine which of the proposed rails would be strongest and stiffest under the passing load, and whether permanently fixing the rail to the chair, for which there were several plans, would be safe in practice. No experiments on malleable iron having ever been made bearing on these points, it was considered better to leave the question unanswered, than to recommend, on no better ground than mere opinion, an expensive trial, which might ultimately prove a failure.

Seeing, however, how desirable it was that such data should be obtained, I proposed to the Directors to undertake a course of experiments, which should be conducted on a scale adequate to the importance of the subject, provided my Lords Commissioners of the Admiralty would allow me the conveniences His Majesty's Dockyard at Woolwich afforded, (which I had every reason to hope they would do, from the liberality I had so frequently experienced from that Board on similar occasions,) and that the Directors would supply such instruments, materials and workmanship, as might be required for the purpose.

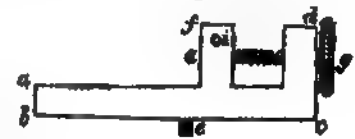

The Admiralty, as I had anticipated, immediately granted my request; and at a public meeting of the proprietors, held at Birmingham, a resolution was passed embodying my proposition. I accordingly commenced, and continued my experiments, till I had elicited such facts as I thought necessary; and having arranged them, as in the following pages, I delivered the results, with a report founded upon them, to the Secretary of the London Committee, to lay them before the Board; which being done, the Directors were pleased to express their high approbation of my labors, and

Fig. 1.

Fig. 2.

Fig. 2.

piece of brass, having a screw *e*; *f* is a piece working in a dove-tail, adjustable for position by the screw *g*, and *i* is another steel pin projecting forward. *a b* is an iron

saddle-piece, with a set screw *s*; and at *f* a hole is tapped to receive the screw *e*, fig. 2; and another saddle piece, exactly like this, is made to receive the screw *e*, of fig. 1.

The iron bars intended to be experimented on were made of the annexed form, about ten feet in length; these, by proper bolts and shackles, were fixed at *a* and *b* in the proving machine;\* the two saddle pieces were then fixed on at the exact distance of 100 inches; the instruments, fig. 1 and 2, screwed into their respective saddle pieces, and a light deal rod hung, by means of two small holes formed in it, (also at the distance of 100 inches,) upon the two pins *i i*; and then by means of the set-screw, fig. 2, the vernier of fig. 1 was adjusted exactly to zero. The pump of the hydraulic press was now put in action, and after one, two, or more tons pressure were on, according to the size of the bar, and every thing brought well to its bearing, the hand was again adjusted to zero, after which the index was read for every additional ton. Here it will be seen, that whatever the bar stretched between the two instruments, the lower pin of fig. 1 was drawn forward, and the index-end thrown back ten times that amount, consequently to ten times the actual amount of the quantity stretched.

It has been observed, that after one, two, or more tons strain were applied [to bring every thing well to its bearing, the index was adjusted to zero, and its reading afterwards carefully registered as each additional ton was added. The strain during the experi-

ment was repeatedly let off, and the index was found to return to zero, till the strain amounted to about nine or ten tons per inch, when the stretching became greater for each ton, and the bar did not any longer regain its original length when the strain was removed, its elasticity with this tension being obviously injured.

These experiments required more attendance than it was possible for one person to give; the adjustment of the weights, the

\* The Lords Commissioners of the Admiralty having been pleased to allow me any facilities His Majesty's Dock-yard at Woolwich afforded for conducting these experiments on a proper scale, the proving machine here referred to is an hydrostatic press, constructed by Messrs. Bramah's, principally for the purpose of testing or proving the iron cables, before they are issued for service. It is an excellent machine of its kind, is capable of bearing a strain of 100 tons and is very sensible to a difference of strain of 1-8th of a ton.

fixed in an immovable mass, as represented in the preceding figures.

Now, in the first place, the elementary deflection at *C* is the same in both beams, because the lengths and loads are the same, and the depths at *C A* equal; but the whole deflection at any other point *P*, will be directly as *M B*<sup>2</sup>, and inversely as *M P*<sup>2</sup>. If, therefore, we call *M B* = *x*, and *M P* = *y*, the sum of all the deflections in the two

beams will be  $\int \frac{x^2}{y^3} dx \Delta$ ,  $\Delta$  being the

sine of deflection at *C*. But in fig. 1, *y* is constant and equal to *d*, (the depth,) while in the latter,

$$y = \frac{d}{l} \sqrt{(2lx - x^2)}$$

*l* being the semi-transverse or length, and *x* any variable distance.

The whole deflections, therefore, in the two cases, are,

Fig. 1:—

$$\text{Deflection} = \int \frac{x^2}{d^3} dx \Delta = (\text{when } x = l) \frac{1}{3} \frac{l^3}{d^3} \Delta$$

And in fig. 2:—

$$\text{Deflection} = \int \frac{x^2}{\frac{d^3}{l^3} (2lx - x^2)^{\frac{3}{2}}} dx \Delta = (\text{when } x = l) \frac{41}{3} \frac{l^3}{d^3} \Delta$$

The deflections, therefore, in the two cases are, with the same weights, as 33 to 41,\* or nearly as 8 to 4, a result fully borne out by subsequent experiment. It is to be observed, also, that this investigation applies only to the deflection when the weight is in the middle of the bar, and that it would be much greater in comparison with the parallel rail towards the middle of its half-length.

This want of stiffness is, I should imagine, but badly compensated by the trifling saving of metal thus effected; for I find that an addition of little more than four pounds per yard, would convert this rail into a rectangular one of the same depth, which would have one-third more stiffness at its middle point, and probably one-half more a little beyond the middle of the half-lengths. I am aware, objections are made to rectangular bars having so much depth of bearing in their chairs, and this may be a practical

\* Experiments have been made from which it has appeared that the fish-bellied rail was stiffer than the parallel rail, which is certainly possible, if the parallel rail be of inferior metal or of injudicious figure; but it is mechanically impossible if the parallel bar be made of the figure here assumed.

defect, on which I shall offer no opinion; at all events, it is well to estimate properly both evils, and then to choose the least.\*

Having thus satisfied myself on the nature of the fish-bellied rail, I proceeded with my experimental inquiries, which I have divided into the following sections:

1. To determine the extension of an iron bar of given area, under different degrees of tension; and hence the force with which the same bar will contract with a given reduction of temperature.

2. The comparative resistance of malleable iron to extension and compression, and thereby the position of the neutral axis.

3. The figure of the area of section, which gives the greatest strength with the same quantity of metal.

4. The strains which bars of given sections are capable of sustaining without injury to their elastic power.

Experiments to determine the quantity which iron extends under different degrees of tension.

With a view to this inquiry, an instrument was made as in the annexed

Fig. 1.

sketch. *a b c d* is a piece of brass, about one-fifth of an inch thick, having an are at top, divided into tenths of inches; *h f g* is a hand, with a vernier, turning freely on a centre *k*; and *i* is a steel pin, about half-an-inch long, projecting perpendicularly forward; the distances *h k* to *k i* being as 10 to 1. *e* is a small end with a screw, for the purpose described below. *a b c d* is another

\* It will be seen in a subsequent page, that by introducing what is called a lower web, that weight for weight, a parallel rail may be made as strong as the fish-bellied, with only an additional depth in the chair of three-quarters of an inch.

reading and registering the index, required each the undivided attention of one individual; the pumping also required to be watched with care. And I have great pleasure in acknowledging the ready assistance I received from Messrs. Lloyd and Kingston, the Engineers of the yard; from Mr. P. W. Barlow, Civil Engineer; as also from Lieutenant Lecount, who came from Birmingham to witness and assist in the experiment.

(To be continued.)

**AERIAL STEAMBOATS.**—Some sixteen or eighteen years since, I passed a day at a tavern in Hanover, N. H. with Mr. Maury, the inventor of the rotary steam engine, used in the glass-house at Lechmere Point, and who has made numerous experiments on light, heat and combustion, and in various branches of mechanics. He stated that he should live to see the mail transported by carriages, propelled by steam, between our largest cities, and that I should live to see it carried in steamboats through the air. On expressing doubts of the practicability of the latter improvement, in the mode of transmitting intelligence, he went into a long argument to prove, that it was not only possible, but absolutely easy of accomplishment. It has been ascertained, he observed, that large weights can be elevated high above the earth, by balloons filled with air, lighter than that of the atmosphere. The first grand step, then has been securely taken, and it is only necessary to apply a power which shall give the balloon a horizontal motion, when a rudder can be applied to guide it, and this can be done by a steam engine, working paddle-wheels as in a steamboat on our waters, but each of the paddles to move on an axis so as to offer no resistance, after having struck the air in one direction. The balloon must be constructed in the form of a fish, or in other words, have length, and such a structure as will be most easily propelled and guided, while space is afforded for the machinery and passengers. He had estimated the requisite size of a steam aërial boat to sustain an engine capable of propelling it sixty miles an hour. After many details, this intelligent, ingenious, and sanguine gentleman, closed his remarks with this bold and prophetic declaration, "You, sir, if you live to the common age of man, will see aërial steamboats rise up out of our large cities every morning, like a flock of wild geese, and take their several directions to the various parts of the Union, laden with the mails and passengers."

Notwithstanding the doubts which are generally entertained of the ultimate benefit to be derived from balloon experiments, a very scientific man, many years since, did foretell the establishment of railroads, and may not be mistaken as to the aërial ocean being successfully navigated. It would not be more wonderful than was the first steamboat which the illustrious Fulton launched upon the Hudson, or the sight of the first locomotive, which sped like the wind from Liverpool to Manchester.—[Boston Atlas.]

**ALLEGANY RIVER.**—The convention which was held at Kittanning on the 18th inst. for the purpose of devising the best method of improving the navigation of the Allegany river, up to the New York Line, has induced many persons to examine the subject carefully, and the result is, the entire conviction of almost every one that it can be accomplished with certainty, and at a very small expense, comparatively. The plan which practical men and those who are acquainted with the stream think best, is that of dams and locks, so as to make a steamboat navigation at all times, except when obstructed by ice; and that interruption would not

continue, on an average, more than ten weeks in each year.

The dams should be made of brush, loose stones, and gravel; and extended across the river, up and down the stream, say 70 feet; with a lock on one side large enough to allow a steamboat carrying 100 tons, with a stern wheel, to pass. The dam should not be more than 4-12 to 5 feet high.

These dams would not interrupt the descending navigation, particularly of lumber, at all; and they can be made at a very small expense.

They have been tested in many of the western streams particularly those which have gravelly bottoms. One of these dams on the Sciota, (Ohio) belonging to a Mr. Musselman, has been in use near thirty years, and has cost scarcely any thing for repair, and does not interrupt the ascent of large Orleans boats, carrying 3 or 400 brls of flour each.

It is the opinion of practical men acquainted with the river, that a judicious expenditure of \$500,000 would give a steamboat navigation for boats of 100 tons, at all seasons, except when obstructed by ice, to the New York State line. This would open another channel of trade to the West, of vast importance; and connected with the Hudson and Erie Rail Road, or with a canal from Rochester to Olean, would furnish the city of New York with the most advantageous connection she ever can have with the vast country in the valley of the Ohio and its tributaries. Merchandise could, by this route, be delivered from the city of New York at the towns on the Ohio six weeks later in the fall, and six weeks earlier in the spring, than by any other route she can command, and at one third less expense.

Any one who will examine the map will see the immense advantages of this route for New York.—[Pittsburg Gazette.]

[From the London Mechanics' Magazine.]

#### DESCRIPTION OF THE FREYBURG SUSPENSION BRIDGE.

Translated from the German, by J. E. Terry, C. E.

The city of Freyburg, in Switzerland, is well known to most travellers for its remarkable locality, being seated partly in a deep and winding valley, watered by the river Saone, and partly on the adjacent high and overhanging cliffs. To arrive at the centre of the town, by the road from Berne, carriages were formerly obliged to descend the steep declivity of the Staalberg. On arriving at Bernegate, it seemed to travellers as if they had already got to the end of their journey, but great was their astonishment to be informed that they had yet to travel for half an hour before they could reach the city—to follow the several large windings of the river, cross it three times, then to ascend the long, difficult, and steep ascent called *Alt Brunnen Strasse* (Old Well-street), which was at all times enough of itself to dismay a traveller, and has proved the death of many a horse. The bad state of the roads, and defective plan of the streets leading to the centre of the city, increased the difficulty of approaching it. Industry, commerce, social life, all felt alike the influence of this almost isolated position of the place. But what could be done? The obstacles seemed insurmountable; the almost perpendicular cliffs on which the chief part of the town stands, seemed to mock the idea of forming a street through them of any tolerable degree of ascent; and had even this been possible, it would only have tended to increase the length of the windings. On the other hand, the idea of erecting a bridge, either of wood or stone, of a sufficient height to overcome the difficulty of the rugged ascents and descents, seemed too daring for contemplation, the height

being upwards of 150 feet, and the length much greater. The expense, too, especially if stone had been employed, would have been out of all proportion to the means of the citizens; for the city is not rich, being but little frequented, and thinly populated, containing, exclusive of the suburbs, no more than 9,000 inhabitants.

Some of the more public spirited and zealous citizens, who had heard of the iron suspension bridges erected in other countries, at length proposed to raise, by subscription, the pecuniary means necessary for ascertaining the applicability of such a structure to the natural circumstances of Freyburg, and, if practicable, of actually constructing it.

As soon as the subscription reached a suitable amount, several eminent engineers were consulted, and after examination of the plans of different competitors, M. Chaley, the famous French engineer, who erected the wire bridges at Beaucaire, Chassey, and several other places in the south of France, obtained the preference. The contract agreed on with him on the 10th February, 1830, was to this effect: that he was to have, at different instalments, 200,000 (Swiss) francs, for the completion of an iron wire bridge; that the expense of the approaches on both sides, and the compensation to individuals for loss sustained in their property, should be defrayed partly by the subscribers and partly by the government; and that the contractor, M. Chaley, subject to certain conditions, should have the enjoyment of the produce from the tolls for 80 years. Some time afterwards, these conditions were considerably modified; it being agreed that M. Chaley's right to the tolls should be limited to 40 years, at the end of which time, the profits are to revert to the subscribers during 59 years, after which the toll is to cease, and the bridge to become the property of the canton, or common property.

The first general meeting of the subscribers took place on the 19th of March, 1830, when they appointed a committee of 10 members (afterwards increased to 20) to superintend the erection of the bridge.

Immediately after these arrangements, the necessary preliminary preparations were entered upon; but the political disturbances which broke out, in 1830-1, in France, and afterwards in Switzerland but particularly in the canton of Freyburg, had a most injurious influence on the undertaking—added to which, differences arose between the contractor and the committee, which tended greatly to retard the project. The general good will of the citizens, however, and the indefatigable zeal and activity of some of the leading members of the committee, recalled ere long the dormant project into life and activity. In March, 1832, the works were entered upon with great zeal, and the first stone of one of the porticos was laid, under the superintendence of the architects Kraser and Brugger. From that time the works were continued in every department without interruption; and, to facilitate their progress, a temporary

bridge was thrown over the river Saone, it being for the ease and advantage of the workmen to get from one side to the other without loss of time.

The finances of the company were all expended, however, long before the bridge approached to its completion. But though the funds were exhausted, the ardor and generous feeling of the subscribers and donors were not. Government, which, from the beginning, had given its particular sanction and protection to the measure, came once more to its assistance, by granting leave for the opening of a lottery, which produced to the company the sum of 80,000 francs.

The work was now once more renewed with vigor, and on the 9th of June, 1834, the subscribers had the gratification of seeing extended across the valley, the first of the numerous wires which form the two main ropes or supports of the bridge. Next followed the fixing of the subordinate suspension wires, and the laying down of the beams to form the foundation or flooring of the bridge. The latter mentioned operation took place, it might be said, in a magical manner. The inhabitants were not a little surprised to find at their gates an unlooked-for, and, for foot passengers, a sufficiently solid bridge, where, ten days before, they had seen only two immense wire-ropes. After this, the other various inferior works soon followed, as the completion of the footway, the erection of the balustrade, &c. At length, on the 8th October, a carriage was driven over the bridge at full gallop, which was followed, on the same day, by the stage, or post coach, from Berne to Freyburg, enthusiastically greeted by a vast number of astonished spectators.

The balustrades, though simply modelled, present, nevertheless, a very handsome appearance. Any vehicle, be it ever so heavily laden, may safely venture over; and although the ear is at first rather startled at the noise of the trampling of horses, yet the most clear-sighted person cannot discover the slightest motion communicated either to the wire ropes or to any other part of the bridge. The traveller passing over does not feel the least vibration, and his astonishment finds no bounds, to think that he has arrived so soon, and in safety, across the deep gulf below.

As has been before observed, the whole structure is suspended by two large ropes of wire, firmly secured at each end, by being let into shafts made for that purpose. At each end the porticos, over which the ropes pass, serve for antagonist supporters, or counterforts. They are built partly of limestone, brought from Neuenberg and Neuenstadt, and partly of sandstone, which is got in the stone quarries in the neighborhood of Freyburg: all the blocks are, by way of greater security, connected with each other by means of iron cramps. The quantity of iron used for this purpose was 570 cwt. The height of the porticos is 65 Berne feet. The opening for the gateway is 45 feet high, 20 feet wide, and 19 feet in depth; the width of each pillar is 14 feet. About

160 feet from the porticos the shafts are situated; their depths are each 58 feet, and their diameters 32 feet. These shafts are hewn out of the rock on both sides, and comprise each three chambers, situated at a certain distance from each other, each containing three immense unwrought blocks of Neuenberg stone, to which the main wire ropes are fastened. The connecting wires or chains, 16 in number, are drawn through these vaults; they rest at the same time on 12 cast iron cylinders, and are held fast by 128 anchors or grapples, of a total weight of 1,024 lbs. These connecting ropes or ties serve the great main wire ropes as auxiliary supports, which bear up on both sides the great beams of the bridge flooring, by means of suspension wires or ties. The length of the main wire ropes is 1,280 feet each. They consist each of 2,000 separate wire threads, which united make a mass of 4,000 threads, or little chains, of a total weight of 960 cwt. Dependent from each of the two main connecting wire ropes, or inverted arch, hang 164 smaller suspension wire ropes, at about 5 feet asunder; these are made fast above through iron loops, and below are connected with hoops of iron, into which the beam ends which support the footway are firmly fastened. The longest of the smaller dependent ropes of wire is 60 feet, and the shortest half a foot; each is composed of 25 single wires, so that the roadway of the bridge is held up by more than 8,000 single wires. The number of beams which form the foundation or platform of the bridge, amounts to 166, held together by 328 hoops of wrought iron. Four lines of beams run longitudinally throughout the whole length of the bridge, upon which rest the two footways. On both sides, to separate the carriage-way from the foot-paths, are strong oaken balustrades, made in the form of St. Andrew's cross, the height of which is 4 feet. The carriage-way is 16 feet, and each footway 3 feet, wide: so that the total width of the bridge is 22 feet. Its total length, including the two counterforts, over which the main wire ropes are passed, is 941 feet; exclusive of the counterforts, its length is 903 feet; the carriage-way alone is 864 feet. Its height above the river, when measured 30th Oct. 1834, was 163 feet.

The quantity of iron used in this work was not less than 80 tons, and of wood 135 tons.

The weight sustained by the two main wire stays is 120 tons; and it is calculated to sustain the amazing and enormous weight of 2,400 tons. J. E. T.

[From the N. Y. Mechanics' Magazine.]

The following letter from Mr. Thomas, of Keeseville, refers to a subject, which, though it has been some time before the public, appears from various causes to have received but a small portion of the attention it merits. To find the true solvent for caoutchouc, or Indian rubber, was a desideratum long sought for by ingenious and scientific men, and great anti-

cipations of the benefits to be derived from it were indulged in, if it could be found; but great as they were, they appear to have borne scarcely the slightest proportion to what proves to be the reality, now that the solvent is found. The benefit of the discovery being secured by letters patent to the discoverer, makes it the business of him and his assigns to extend the application of it to its various uses; but so amazingly extensive is its usefulness, that years, and even ages, may pass away, before it shall be applied to all the purposes it is calculated to answer. When we see its wonderful efficiency, not only in rendering cloth impervious to air and water, but in joining the edges together without sewing—when we see not only cushions to sit on, but beds to lie on, filled with air, so that a stage passenger can sit all day upon a seat, and sleep at night upon a bed, infinitely softer than down—and deflating both in a moment, wrap them up and tuck them in a corner of his trunk or walle t—who, after seeing all this, will attempt to prescribe limits to the uses of such an invention, or who would be without a suit of clothes of it to wear in wet weather, if he could get them? I know not what calculations are made by the proprietors to extend it, but I will venture to say, when the patent expires, if not before, few sails will be seen which are not prepared with Indian rubber; and I think, also, the Mechanics' Magazine may be benefitted by the communications of Mr. Thomas. S. B.

Keeseville, Clinton co., N. Y., May 17, 1835.

S. BLYDENBURGH, Esq.: Sir,—In this age of "Indian rubber," will you permit me to submit to you, whether the application of that article to the sails of vessels of every description would not be highly advantageous to the interests of merchants and the government? Some of the advantages which have occurred to me as likely to be derived from its use, are the preservation of the cloth from mildew, its rendering the texture firmer, more elastic, and of course capable of enduring greater tension when in use. In wet weather the sails would be lighter, and more easily managed. I think if coal tar be the solvent used in making the varnish, the expense attending the process of covering the cloth would not be equal to the benefits arising from its use; but in this I may be in error.

I can think of but one objection to its use: it is possible that spontaneous combustion might ensue when sails should be stowed away in large quantity, and in a close, warm situation.

If you think, sir, the suggestion has any value, please communicate it (if new) to your friend Mr. Minor, of the Mechanics' Magazine, and oblige, very respectfully, your obedient servant,

J. THOMAS.

### On the Use of Plated Glass as Sheathing for Ships' Bottoms.

To the Editor of the Mechanics' Magazine:

Sir,—Much ingenuity has been employed for a long time to invent a sheathing, or bottom, for ships, which would not be subject to corrosion by salt water, and at the same time avoid the accumulation of animalculæ and dirt attendant upon most bottoms which have heretofore been used.

I have thought that the following plan would be free from the usual difficulties, and have taken the liberty of introducing it to your notice. It is possible, however, that it may not be new, and that it may have been tested, but, as far as I have been able to learn, it has not. It consists of plates of different dimensions, size, thickness, and shapes, adapted to the size and form of the ship to be plated. They are to be made from glass, and the same earth and clay from which the wares denominated stone, earthen, and crockery wares, are made, (or from any others capable of being applied to such purposes,) and are to be polished in the same manner, or in any other way, on that surface intended to be exposed to the water. They are to be made with holes of sufficient size to admit screws or nails to pass through them for fastening. These holes are to be so formed, that the nails or screws shall catch and hold the plates below their outer surface. The cavities between the heads of the screws or nails, and the outer surface of the plates, and the crevices, or space between the plates, are to be filled with water lime, or any other matter, or composition of matter, which will protect the heads of the screws or nails from corrosion, and the bottom of the ship from the water, and give the plating a smooth and even surface.

If I am acquainted with the nature of the articles from which the above plates are proposed to be made, they will not be subject to corrosion, will resist all attacks by animalculæ, keep clean and smooth, and will not be worn by the friction of water. By their being made about one inch, or an inch and a half in thickness, and about a foot square, they will possess much strength. There is an objection which may be insuperable: that is, their danger of being broken by anchor cables. If that be an objection, perhaps it might be obviated by using copper, or some plan might be invented to prevent the cables from coming in contact with the bottom.

I presume that others may have thought of using glass for ships' bottoms, and I have heard it suggested that glass would do away all difficulties; but the suggesters have been at a loss to know how it should be put on to bottoms. If the putting of it on is all the difficulty, it is obviated by making it into such plates as I have described, and I am not aware that this plan has ever been proposed or tried by any person.

Many would look upon a plan for glass or stone ship bottoms as ridiculous; but when they come to consider, that these bottoms are composed of plates of a small size, and of considerable thickness, which renders them much stronger than a whole bottom of glass or stone, and far less liable to be broken, and if broken easily repaired, they might be inclined to regard it more favorably. The expense for plating a ship with these could not vary much from the present expense of coppering; but when a ship is once plated with glass, it is, as it were, plated forever, unless by some sudden blow upon the bottom it might be broken. We do not, however, expect a ship to strike the ground, or a rock, without doing great damage, whatever may be her bottom.

I have thus troubled you with an imperfect and disconnected statement of what I conceived might be an improvement in ship's bottoms; and I have endeavored to give you a few of my ideas in relation to it. They may be correct, and they may be grossly incorrect. If it should be deserving of any notice by one so capable as yourself to judge of its merit or demerit, I shall be much gratified and honored; if it is not, I shall not be disappointed. If my plan, or any part of it, shall be worthy of notice, I no doubt shall find that notice in your valuable Magazine; if it is not, I shall expect it to be treated accordingly.

I shall, in any event, have the consciousness of having made an endeavor to benefit mankind.

Yours, very respectfully,  
ROBIN.

Utica, March 31, 1835.

The letter we publish from Chicago, exhibits a curious state of things in that—newly discovered region we may almost call it—deserving of attention.

The land sales, wherever settlers, as they call themselves, but squatters in fact, have taken previous possession, become absolutely nominal—since these settlers combine to prevent, by force, other parties from bidding for the land.

Such was the ingress, it will be perceived, of strangers, to attend the land sales, that neither food nor lodging was to be obtained for love or money. It would be worth while for emigrants to carry with them some provisions, and a tent or two—the latter, in these piping times of peace, might be had dog cheap.

Extract from a letter dated, Chicago, June 18th.

"Mechanics wages are very high here, being \$1 50 to \$1 75, per day. Provisions of all kinds are also high, owing to the number of emigrants passing through, and to the extraordinary number of persons attending the land sale. Flour sold here yesterday at \$20; and 25, per barrel is asked to-day. Butter, 37 1-2 per lb.; Eggs 25 per doz; Potatoes, \$1 50 to \$2 per bushel; Oats \$1 a 1 25; Corn, \$1; Wheat, 80 cents, but no mills to grind it. We shall probably, however, have supplies from Lake Erie soon—or there will be a famine.

Hundreds have left here for want of accommodations. Several who came in the steamboat Thomas Jefferson to attend the land sale, returned in her, because they could get neither victuals to eat, nor a floor to sleep on. Hundreds who came before them, have no other bed than the floor, and many sleep in covered waggons in the open air.

The sales of public Lands have gone quietly on until to-day—the settlers bidding for that on which they had settled at \$1 25 per acre, when one or two speculators undertook to out bid them; this caused an immediate skirmish in which the speculators were rather roughly handled—not however very much injured. It is generally understood that the settlers are to be allowed to have the land on which they have located at government prices. They have in one township organized, and are determined, at all hazards, not to be interfered with.

June 19th.—I have but a moment to add that there has been no disturbance to-day, between the settlers and other purchasers, as was apprehended—except in one or two instances; and those were immediately quelled. There has been paid into the Land Office, up to 6 P. M. this evening, over \$200,000.

Flour sold this day at \$25, and \$28 per barrel was offered for more, and refused; I am happy however to say, that a vessel has arrived from Lake Erie, which is said to have some on board.

The following vivid description of the unparalleled emigration to Illinois, is taken from the 2d number of the Chicago American, of 13th inst. published in the village of Chicago, by Thomas O. Davis, recently of this city. Indeed the "Chicago American" is itself a striking evidence of the rapid growth, and increasing importance of that country as it is but a few months since its enterprising proprietor was, an apprentice, and more recently a journeyman in this city; in both of which stations he did himself credit; as we are confident he will in his present capacity, as proprietor, publisher, and Editor of a journal in this miniature city of the "far West."

The paper is handsomely printed on good paper, with new type, and evinces both talent and industry. A specimen of number one and two may be seen at the store of Messrs. T. & C. Wood, Stationers, next door to this office, who are Agents to receive and forward subscriptions and advertisements.

"THE CRY IS STILL THEY COME."—The tide of emigration which is flowing in, this season, far exceeds that of any former period. The flood-gates of enterprise seem to be let loose upon us, and multitudes are crowding on to this young land, as if the pestilence were behind, eager to find a better home, where they can build their fortunes and their hopes, and enjoy the plenty which our fat fields yield to the hand of industry. In addition to the actual emigrants that are now pressing into this region, the approaching land-sale is bringing into our town a crowd of strangers, and capitalists ready to avail themselves of the benefits of the rapid rise in value of the real estate of the country. The actual population of Chicago, we cannot estimate with any degree of accuracy, but it is now supposed to be between 2500 and 3000. Strangers, to the amount of some hundreds more, fill our public houses and streets, our wharves are covered with men, women and children, just landed from the vessels, and even some store houses have been thrown open to receive the unsheltered emigrants, who had else remained under the open sky upon the wharves. Some build tents upon the spot where they are landed from the boat, in the middle of our streets, then raise them and move on. The cry is "Westward Ho!" and they press on still deeper in the interminable prairies; history seems to be filling up the prophecy of the Bishop of Cloyne; the "Star of Empire" is taking its way westward, and in its last ascendant shall shine upon the noblest kingdom. The emigration to Illinois this season, is chiefly crowding into the northern part of the State, Cook county, which two years ago exhibited a few scattered dwellings, along the groves or by the streams, is now rife with thriving settlements; and some smart villages have arisen too, as by enchantment. The solitary inhabitant of a grove, has seen a community suddenly gather around him. Schools are actually in successful operation, where a year since was but a solitary emigrant. But we have land enough yet which offers itself to the moulding hand of the emigrant—yet untouched, and invites the hand of cultivation.

La Salle, and other neighboring counties at the north, are receiving a similar influx of emigration, though perhaps less abundantly than Cook. We are informed that they are rapidly settling in the Rock River country—a beautiful, fertile, and healthy region—and that hundreds have within the last few months, occupied the region before inhabited by a dozen or more. We rejoice in the fair prospect and rapid growth of our State. Our fat fields will soon be reduced to culture; and we trust, too, that our rivers will be deepened and brought into communication with each other, and with the great commercial marts of the nation, by artificial channels or roads; and thus our produce be made valuable by the convenience and facilities of good markets. Let emigrants come,—we have an immense domain for them.—More than twenty millions of acres of land in Illinois are spread out before them. Richer fields were never bared to the sun.

We welcome them to our young home of enterprise and prosperity. We welcome them to partake with us the pleasures as well as the hardships of a new country, and to enjoy with us the fond hopes in prospect.

NEW-YORK AMERICAN.

JUNE 27—JULY 3, 1833

## LITERARY NOTICES.

THE AMERICAN QUARTERLY REVIEW, No. xxxiv., for June. Philadelphia. LYDIA R. BALEY.—We like this number much, though we are somewhat tardy in noticing it. The first paper, on *National Music*, is entertaining, though as a nation we have not, and from our heterogeneous origin and composition, cannot have any such. Moreover, music, like architecture, seems to us as yet, we confess, a stranger to our soil—at least among its white denizens. In both these particulars, we take after our English ancestors.

The paper on *Shirreff's Tour*, in this country, with the extracts given from the book, lead us to hope it may be republished here. Mr. Shirreff is "a plain East Lothian farmer," who visited this country with a view to determine, by his own observation, whether it would be expedient for a younger brother of his, to emigrate hither. He is evidently a scientific, as well as practical agriculturalist—and withal, possessing strong sound sense and a keen spirit of observation. We annex at hazard some quotations.

*Visit to a celebrated seat upon the North River.*—"We left New York early in the morning, by the Albany steam-boat, for Hyde Park, after viewing which we returned to the landing-place on the river Hudson, and, at half-past twelve at night, slept on board of a steam-boat which landed us at Albany a little after seven next morning. I got on deck at four, when passing the town of Hudson; the wind was blowing high from the north, and piercingly cold.

"Hyde Park, the seat of Doctor Hosack, is the most celebrated in America, and which Mr. Stuart describes as being 'embellished as a fine residence and fine grounds in England.' The house is situated some hundreds of feet above the level of, and at a considerable distance from, the Hudson, the intervening grounds being finely undulating.—In front of the house there is a road, leading from the landing-place on the river, along a small stream, over which there is an elegant wooden bridge, and several artificial cascades have been formed in its channel. The house is composed of wood, as well as the offices and lodges, painted white, and are very neat of their kind. The conservatory had been dismantled a few days before our arrival, by placing the plants in the open air: the collection seemed extensive and well kept.—The flower garden is small, the walks limited, and both destitute of beauty. I am aware that most of the evergreens which impart loveliness to the residences in Britain cannot withstand the rigors of an American winter, but this circumstance is no excuse for the nakedness of Hyde Park walks, the aid of many native plants having been disregarded. The matchless beauties of the situation have not only been frequently neglected, but destroyed by stiff, formal, naked walks, and the erection of temples resembling meat-safes, without a climbing plant, which the country produces in endless variety, to hide their deformity, and harmonize them with the surrounding scene. In short, while I greatly admire the situation of Hyde Park, I do not recollect having seen a celebrated place where nature had done so much, and man so little, to render beautiful. The embellishments at Hyde Park, contrasted with those met with every day in Britain, place American landscape-gardening immeasurably behind, if it can be said to exist.

"The progress of a people in refinement and taste, manifested in a combination of nature and art, is commonly the work of time, and the decoration of grounds an unproductive investment of capital. Thus the residences of England having descended for ages in the same line, without the power of the possessors' changing their destination, may be said to represent the accumulated savings, labors, and tastes of many generations. In America the country has not been long possessed by the present owners, and property does not necessarily descend in the same line; and if to these causes be added the high price of labor, and the scarcity of capital, the state of the residences will be sufficiently accounted for. Dr. Hos-

ack has great merit in what he has accomplished, but it is mockery to compare his grounds, in point of embellishment, with the fine places in Britain, which have originated from circumstances which America is not likely soon to experience.

"Throughout the whole of my transatlantic tour, the inhabitants of the country manifested perfect indifference to the beauties nature. It was rarely I could learn the name of a plant, with the exception of trees. Nurserymen, seedsmen, and farmers, were, generally, unacquainted with varieties, and, with the exception of two or three individuals, no one seemed interested in the matter. Rhododendrons grow as plentifully in many parts of the Eastern States as furze in Britain, yet I saw vast numbers of this plant shipping at Liverpool for Philadelphia, although millions of the same variety could have been obtained for the trouble of lifting, at no great distance from the city. Gardens and nurseries were overrun with weeds, and did not display beauty either in decoration or arrangement."

In a short time we find Mr. Shirreff at Lowell, Massachusetts, and the reflections suggested by the state of things in that manufacturing town, deserve to be extracted:

"The females engaged in manufacturing amount to nearly 5000, and as we arrived at Lowell on the afternoon of Saturday, we had an opportunity of seeing those connected with some of the largest cotton factories retiring from labor. All were clean, neat, and fashionably attired, with reticules hanging on their arms, and calashes on their heads. They commonly walked arm in arm without displaying levity. Their general appearance and deportment was such that few British gentlemen, in the middle ranks of life, need have been ashamed of leading any of them to a tea-party. Next day, being Sunday, we saw the young females belonging to the factories going to church in their best attire, when the favorable impressions of the preceding evening were not effaced. They lodge, generally, in boarding houses, and earn about 8s. 6d. sterling per week, independent of board; serving girls earn about 4s. 3d.

"The recent introduction of large manufacturing establishments, thin population, and ample reward of labor, account for the apparent comfort and propriety of the Lowell young women. The situation of the manufacturing class in Britain is very different: nurtured amidst poverty and vice, they toil in crowded and unwholesome factories from infancy, often disregarded by parents and employers, and attaining maturity ruined in constitution and morals, with few of the sympathies of humanity."

"This village may be taken as an instance of the giant strides by which the United States are advancing to greatness, and the immeasurable water power nature has lavished on them. The canal supplies more water than the present machinery requires; and, after inspecting the surplus in the canal and the rivers, I am of opinion, there is water enough to propel nearly one hundred times the machinery at present employed, and which might employ a population of above a hundred thousand souls.

"Britain is said to owe much of her greatness to the supply of coal with which she has been blessed; but however extensive and available it may be, the water power of the United States will excel it in cheapness and magnitude. The price of labor is, and will likely continue, much cheaper in Britain than in the United States, which seems the only circumstance that can ultimately give a superiority to the manufactures of the former."

On the score of domestic manners, the general deportment of the people, and the habitual civility of all classes among them, the testimony of Mr. Shirreff is to the following effect:—

"Although I did not often witness the domestic manners of the Americans, my opportunities of meeting the inhabitants of the United States in public were frequent, and the impressions imbibed during my intercourse with them were different from what the accounts of others led me to expect. Many travellers who have written on the subject were perhaps ill qualified to form a just estimate of American manners and character, from the sphere of society in which they themselves had previously moved. No action nor associate of British aristocracy, who has not been brought into familiar intercourse with the middling and lower orders of his own countrymen, is likely to do justice to the Ame-

ricans, and the tenor of many of the remarks which have been given to the world on the subject is evidence of the writers never having before associated with the class of people to whom they allude. The inhabitants of Britain, in private and public life, being divided into grades, some individuals are altogether unacquainted with the manners and customs of the classes below them. And as Englishmen of high pretensions and refinement, on reaching America, mingle on terms of equality at public tables and in conveyances with the commonest operatives, they feel disgusted with the manners of the people around them, without considering they belong to a different class from their own associates at home. In Britain, a person of rank is generally regarded with respect by the classes below him. In the United States, rank seldom meets with or expects deference from the people, and the humblest citizen familiarly enters into conversation with every individual who addresses him. This self-possession is often taken for forwardness, and their unembarrassed conversation for insolence. In Britain the different classes of population generally remain distinct, and many of their excesses are hid from common gaze. In most parts of the United States, the bar-rooms of hotels form the only scenes of tippling, and, being at all times open to the public, a traveller is apt to consider the people more dissipated than they really are. Were a gentlemanly foreigner to meet the lowest class of the people of England at table, and associate with them in their haunts of vice, his adventures would form a high-colored picture of English manners and society."

"On first reaching the United States, the plainness of the people's manners appeared remarkable. In all classes there was a total absence of grimace and corporeal token of respect, with corresponding sounds of address, an expression of obligation or thankfulness seldom being heard. In consequence the inhabitants appear as far behind the British as the French exceed them. But, on the other hand, vulgarity, rudeness, or insolence, is almost never met with in the humblest walks of life. Mechanics and storekeepers ride in the same vehicle, and sit down at the same table, with the most polished members of society; all seem desirous of behaving well to each other, a rude or indelicate remark never being made, nor a disgusting practice indulged in. On one occasion only I met with revolting behaviour, at the table of the Washington hotel, during my first residence at New York. On my second visit, I found the individual still an inmate of the house, in which he had lodged for 14 years. He was an eccentric character, and originally from England.

"A general propriety of deportment and softness of manners pervades the lower classes, and that coarseness, which is sometimes met with in Britain, does not appear to exist in the United States; but certain circles of society in Britain seem to have a higher polish than what is to be met with in America, and perhaps the general standard of manners of both countries is not widely different. The lower orders of the United States are, however, beyond all question, greatly superior in refinement and intelligence to the lower orders of Britain."

"The civility of all classes in the United States is so universal, that during my intercourse with the inhabitants, I scarcely experienced an indication of insolence, and never observed that democratic sauciness which I was taught to expect among the lower orders. Every individual feels that he is independent, and never alludes to the subject.—The case is, however, different in Canada, where some British emigrants seldom let an opportunity escape of telling a well-dressed person, that 'this is a free country, and that he does not care a \* \* \* for any man.' The emancipated bondsmen alone bloats of being free from fetters. A foreigner, however, who arrogates to himself superiority in the United States, will be despised by the meanest of the people, and his money will neither purchase their attention nor services. The United States which I visited, seem to me an excellent place for teaching an overweening person a due estimate of himself and his fellow mortals. Twelve months' intercourse with the people would greatly improve the fagged and fagging youthful aristocracy of Britain. Their haughtiness of demeanor, and acerbity and impatience of temper would be changed, and they would return home with a just sense of the place they occupy in the world, and qualified to discharge the important duties they owe society.—

Every Briton who has mingled with the people for any length of time, and practised self-examination, will testify to the truth of my remarks."

**PORTRAITS OF THE PRINCIPAL REFORMERS OF THE 16th century, &c., 1 vol.** N. Y.—VAN NOSTRAND AND DWIGHT.—In this neatly printed and well-executed little volume, we have a brief history of the Reformation, and following it, portraits, with short biographical notices, of the leading Reformers from John Wickliffe to John Knox. The portraits are medallions, from Ormsby's machine.

**THE STUDENT**, a series of papers, by the author of *Eugene Aram*. 2 vols. New York. HARPER & BROTHERS.

We have before alluded to this collection, by Bulwer, of various essays—some of which have appeared before. It is one that makes up two very agreeable, and withal, instructive volumes, written in a style which "utters in prose, what are the ordinary didactics of poetry."

In the second volume are "The Conversations of an ambitious Student in ill health," which attracted so much attention, as they appeared originally, in the *New Monthly Magazine*.

We learn, for the first time, from the remarks prefixed to this collection, that *Bulwer* is engaged, and has for some years, at intervals, been, "upon a historical work." No indication is given as to its subject, or the period to which it refers.

**A DETAIL OF SOME PARTICULAR SERVICES PERFORMED IN AMERICA** during the years 1776, 7, 8, and 9, &c. &c. N. Y.—This is a very curious publication. The narrative purports to be compiled from journals and original papers, supposed to be chiefly taken from the journal kept on board of the ship *Rainbow*, commanded by Sir George Collier, while on the American station, during the period above referred to. It is printed for our fellow citizen ITHIEL TOWN—distinguished as an Architect—from a manuscript purchased by him in London, in 1830, at a public sale of autographs and manuscripts, from the collection of a private gentleman. It bears internal evidence of being genuine, and is valuable as a memoir to serve for future historians.

**HORSE SHOE ROBINSON.** A tale of the *TORY ASCENDENCY*—by the author of *SWALLOW BARN*—2 vols.: *PHILAD., CAREY, LEA & BLANCHARD.*—In *Swallow Barn* the author gave in a somewhat disconnected story, a series of pictures of Virginia life—which presented in admirable relief, its peculiarities. It was in this, rather than in the interest of the story as a whole, that his success laid.

The work now before us, is of a higher cost and higher execution. It is indeed fraught with stirring incidents, and the characters are drawn with a master's hand. The blacksmith, *Robinson*, from whom the work takes its name—*Mildred Lindsay*, and her gallant brother, are finely conceived, and never falter in the course of the narrative.

"The political and documentary history of the revolutionary war," it is well said by the author, "has been written. Its romantic or picturesque features have been left for the industrious tribe of chroniclers." It is as one of them, that the author of *Swallow Barn* now addresses the public, and he has assuredly extracted from the many unsung, and unhonored, but not less daring and romantic incidents of the fierce civil war in the South, before GREENE had turned the tide of victory, the materials for two charming volumes.

Historical accuracy is preserved—and indeed the chief personages, including the blacksmith Hero, are also historical, though some license has of course been taken in the construction of the story.

Mr. KENNEDY, for it is no secret that he is the

author, has abundantly shown in this work, how fruitful our revolutionary struggle is, in incidents which the pen of genius may avail of, for the historical romance—and he has shown too, his ability and fitness to wield that pen.

*An adventure wherein it is apparent that the actions of real life are full as marvellous as the inventions of romance:*

On the morning that succeeded the night on which Horse Shoe Robinson arrived at Musgrave's, the stout and honest sergeant might have been seen, about eight o'clock, leaving the main road from Ninety-Six at the point where that leading to David Ramsay's separated from it, and cautiously urging his way into the deep forest, by the more private path into which he had entered.—The knowledge that Innes was encamped along the Ennoree, within a short distance of the mill, had compelled him to make an extensive circuit to reach Ramsay's dwelling, whither he was now bent; and he had experienced considerable delay in his morning journey, by finding himself frequently in the neighborhood of small foraging parties of Tories, whose motion he was obliged to watch for fear of an encounter. He had once already been compelled to use his horse's heels in, what he called, 'fair flight'—and once to ensconce himself, a full half hour, under cover of the thicket afforded him by a swamp. He now, therefore, according to his own phrase, 'dived into the little road that scrambled down through the woods towards Ramsay's, with all his eyes about him, looking out as sharply as a fox on a foggy morning'—and with this circumspection, he was not long in arriving within view of Ramsay's house. Like a practised soldier, whom frequent frays has taught wisdom, he resolved to reconnoitre before he advanced upon a post that might be in possession of an enemy. He therefore dismounted, fastened his horse in a fence corner, where a field of corn concealed him from notice, and then stealthily crept forward until he came immediately behind one of the out-houses.

The barking of a house-dog brought out a negro boy, to whom Robinson instantly addressed the query,

'Where is your master, you powder monkey?—stop that dog!'

'Yaick—ya hound!'—cried the boy, aiming a blow at the dog's head with his hand.—'What is you making a fuss about!—Massa done gone, sa.'

'Where?'—inquired the sergeant.

'Got on his critter, arter he done his breckfus, and started away, like all de world.'

'Your mistress?'

'She home, sa, shelling beans.'

'Any sodgers or strangers there?'

'All gone, sa,'—replied the negro.

Robinson, having thus satisfied himself as to the safety of his visit, directed the boy to take his horse and lead him up to the door. He then entered the dwelling.

'Missus Ramsay,' said he, walking up to the dame, who was occupied at a table, with a large trencher before her, in which she was plying that household thrift which the negro described,—'luck to you, ma'am, and all your house! I hope you haven't none of these clinking and clattering bul-lies about you, that are as thick over this country as the frogs in the kneading troughs—that they tell of.'

'Good lack—Mr. Horse Shoe Robinson!' exclaimed the matron, offering the sergeant her hand.—'What has brought you here?—What news?—Who are with you?—For patience sake, tell me!'

'I am alone,'—said Robinson—'and a little wet-tish, missus,'—he added, as he took off his hat and shook the water from it:—'it has just sot up a rain, and looks as if it was going to give us enough on't.—You don't mind doing a little dinner work of a Sunday, I see—shelling of beans, I spose, is tantamount to dragging a sheep out of a pond, as the preachers allow on the sabbath—ha, ha!—Where's Davy?'

'He's gone over to the meeting-house on Ennoree, hoping to hear something of the army at Camden:—perhaps you can tell us the news from that quarter?'

'Faith, that's a mistake, missus Ramsay.—Though I don't doubt that they are hard upon the scratches, by this time. But, at this present speaking, I command the flying artillery. We have but one man in the corps, and that's myself; and all the guns we have got is this piece of ordi-

nance, that hangs in this old belt by my side, (pointing to his sword)—and that I captured from the enemy at Bradstock's. I was hoping I might find John Ramsay at home.—I have need of him as a recruit.'

'Ah, Mr. Robinson,—John has a heavy life of it—over there with Sumpter. The boy is often without his natural rest, or a meal's victuals; and the general thinks so much of him, that he can't spare him to come home. I hav'n't the heart to complain, as long as John's service is of any account, but it does seem, Mr. Robinson, like need-less tempting of the mercies of Providence. We thought that he might have been here to-day; yet I am glad he didn't come—for he would have been certain to get into trouble. Who should come in this morning, just after my husband had cleverly got away on his horse, but a young cock-a-whoop ensign, that belongs to Ninety-Six—and four great Scotchmen with him, all in red coats; they had been out thieving, I warrant, and were now going home again. And who but they! Here they were, swaggering all about my house—and calling for this—and calling for that—as if they owned the free simple of every thing on the plantation. And it made my blood rise, Mr. Horse Shoe, to see them turn out in the yard and catch up my chickens and ducks, and kill as many as they could string about them—and I not daring to say a word; though, I did give them a piece of my mind too.'

'Who is at home with you?'—inquired the sergeant eagerly.

'Nobody but my youngest boy, Andrew,'—answered the dame. 'And then, the filthy, toping rioters,—she continued, exalting her voice.

'What arms have you in your house?'—asked Robinson, without heeding the dame's rising anger.

'We have a rifle, and a horseman's pistol that belongs to John—They must call for drink too, and turn my house, of a Sunday morning, into a tavern.'

'They took the route towards Ninety-Six, you said, missus Ramsay?'

'Yes,—they went straight forward upon the road. But, look you, Mr. Horse Shoe,—you're not thinking of going after them?'

'Isn't there an old field, about a mile from here, on that road?'—inquired the sergeant, still intent upon his own thoughts—

'Certain,'—replied the hostess.—'You must remember the cobbler that died of drink on the road side?'

'There is a shabby, racketty cabin in the middle of the field—am I right, good woman!'

'Yes.'

'And nobody lives in it.—It has no door to it?'

'There ha'n't been a family there, these seven years.'

'I know the place, very well,'—said the sergeant thoughtfully,—'there is woods just on the side of it.'

'That's true,'—replied the dame:—'but what is it you are thinking about, Mr. Robinson?'

'How long before this rain began, was it that they quitted the house.'

'Not above fifteen minutes.'

'Missus Ramsay—bring me the rifle and pistol both—and the powder horn and bullets.'

'As you say, Mr. Horse Shoe,'—answered the dame as she turned round to leave the room,—'but I am sure I can't suspicion what you mean to do.'

In a few moments the woman returned with the weapons, and gave them to the sergeant.

'Where is Andy?'—asked Horse Shoe.

The hostess went to the door and called her son, —and, almost immediately afterwards, a sturdy boy, of about twelve or fourteen years of age, entered the apartment, his clothes dripping with rain. He modestly and shyly seated himself on a chair near the door with his soaked hat flapping down over a face full of freckles, and not less rife with the expression of an open, dauntless hardihood of character.

'How would you like a scrummage, Andy, with them Scotchmen that stole your mother's chickens this morning?'—asked Horse Shoe.

'I'm agreed,'—replied the boy,—'if you will tell me what to do.'

'You are not going to take the boy out on any of your desperate projects, Mr. Horse Sho?—'said the mother, with the tears starting instantly into her eyes.—'You wouldn't take such a child as that into danger?'

'Bless your soul, missus Ramsay, there arn't no danger about it! Don't tek on so. It's a thing

that is either done at a blow, or not done,—and there's an end of it. I want the lad only to bring home the prisoners for me, after I have took them.'

'Ah, Mr. Robinson, I have one son already in these wars—God protect him!—and you men don't know how a mother's heart yearns for her children in these times. I cannot give another,'—she added, as she threw her arms over the shoulders of the youth and drew him to her bosom.

'Oh, it aint nothing,'—said Andrew, in a sprightly tone.—'It's only snapping a pistol, mother,—pooh!—If I'm not afraid, you oughtn't to be.'

'I give you my honor, mistress Ramsay,'—said Robinson,—'that I will bring or send your son, safe back in one hour; and that he shan't be put in any sort of danger whatsoever;—come,—that's a good woman!'

'You are not deceiving me, Mr. Robinson?—asked the matron, wiping a way tear.—'You wouldn't mock the sufferings of a weak woman in such a thing as this?'

'On the honesty of a sodger, ma'am,'—replied Horse Shoe,—'the lad shall be in no danger,—as I said before,—whatsoever.'

'Then I will say no more,'—answered the mother.—'But Andy, my child, be sure to let Mr. Robinson keep before you.'

Horse Shoe now loaded the fire-arms, and having slung the pouch across his body, he put the pistol into the hands of the boy; then shouldering his rifle, he and his young ally left the room. Even on this occasion, serious as it might be deemed; the sergeant did not depart without giving some manifestation of that light-heartedness, which no difficulties ever seemed to have power to conquer. He thrust his head back into the room, after he had crossed the threshold, and said with an encouraging laugh, 'Andy and me will teach them, Mistress Ramsay, Pat's point of war, we will surround the ragamuffins.'

'Now Andy, my lad,'—said Horse Shoe, after he had mounted Captain Peter,—'you must get up behind me. Turn the lock of your pistol down,' he continued, as the boy sprang upon the horse's rump, 'and cover it with the flap of your jacket, to keep the rain off. It won't do to hang fire at such a time as this.'

The lad did as he was directed, and Horse Shoe having secured his rifle in the same way, put his horse up to a gallop and took the road in the direction that had been pursued by the soldiers.

As soon as our adventurers had gained a wood, at the distance of about half a mile, the sergeant relaxed his speed and advanced at a pace but little above a walk.

'Andy,' he said—'We have got rather a ticklish sort of a job, before us—so I must give you your lesson, which you will understand better by knowing something of my plan. As soon as your mother told me that these thieving villains had left her house about fifteen minutes before the rain came on, and that they had gone along upon this road, I remembered the old field up here, and the little log hut in the middle of it; and it was natural to suppose that they had just got about near that hut, when this rain came up,—and then, it was the most supposable case in the world, that they would naturally go into it, as the driest place they could find. So now, you see, it's my calculation that the whole batch is there at this very point of time. We will go slowly along, until we get to the other end of this wood, in sight of the old field—and then, if there is no one on the look-out, we will open our first trench;—you know what that means, Andy?—'

'It means, I s'pose, that we'll go right smack at them,'—replied Andrew.—'

'Pretty exactly,'—said the sergeant.—'But listen to me. Just at the edge of the woods you will have to get down, and put yourself behind a tree. I'll ride forward, as if I had a whole troop at my heels,—and if I catch them, as I expect, they will have a little fire kindled and, as likely as not, they'll be cooking some of your mother's fowls.'

'Yes—I understand,'—said the boy eagerly.—'

'No you don't,'—replied Horse Shoe:—'but you will when you hear what I am going to say. If I get at them onawares, they'll be mighty apt to think they are surrounded, and will bellow like fine fellows, for quarters. And, thereupon, Andy, I'll cry out 'stand fast,'—as if I was speaking to my own men,—and when you hear that, you must come up full tilt, because it will be a signal to you that the enemy has surrendered. Then it will be your business to run into the house and bring out the muskets, as quick as a rat runs through a

kitchen: and when you have done that,—why all's done. But if you should hear any popping of fire arms—that is, more than one shot, which I may chance to let off—do you take that for a bad sign, and get away as fast as you can heel it. You comprehend?'

'Oh yes,'—replied the lad,—and I'll do what you want,—and more too, may be, Mr. Robinson.' 'Captain Robinson,—remember, Andy; you must call me captain, in the hearing of these Scotchmen.'

'I'll not forget that neither,'—answered Andrew.

By the time that these instructions were fully impressed upon the boy, our adventurous forlorn hope, as it may fitly be called, had arrived at the place which Horse Shoe had designated for the commencement of active operations. 'They had a clear view of the old field; and it afforded them a strong assurance that the enemy was exactly where they wished him to be, when they discovered a smoke arising from the chimney of the hovel. Andrew was instantly posted behind a tree, and Robinson only tarried a moment to make the boy repeat the signals agreed on, in order to ascertain that he had them correctly in his memory. Being satisfied from this experiment that the intelligence of young Ramsay might be depended upon, he galloped across the intervening space, and, in a few seconds, abruptly reigned up his steed in the very doorway of the hut. The party within was gathered around a fire at the further end; and, in the corner opposite the door, were four muskets thrown together against the wall. To spring from his saddle, thrust himself one pace inside of the door, and to level his rifle at the group beside the fire, was a movement which the sergeant executed in an instant,—shouting at the same time—'

'Surrender to captain Robinson, of the Free Will Volunteers, and the Continental Congress—or you are all dead men!—Halt,' he vociferated in a voice of thunder, as if speaking to a corps under his command:—'file off, cornet, right and left, to both sides of the house. The first man that budges a foot from that there fire place, shall have fifty balls through his body.'

'To arms!' cried the young officer who commanded the squad inside the house. 'Leap to your arms, men! Why do you stand, you villains?' he added, as he perceived his men hesitate to move towards the corner, where the muskets were piled.

'I don't want your blood, young man,' said Robinson, coolly, as he still levelled his rifle at the officer, 'nor that of your people:—but by my father's son, I'll not leave one of you to be put upon muster roll, if you move an inch!'

Both parties now stood, for a brief space, eyeing each other, in a fearful suspense, during which there was an expression of mixed doubt and anger visible on the countenance of the soldiers, as they surveyed the broad proportions, and met the stern glance of the sergeant—whilst the delay, also, began to raise an apprehension in the mind of Robinson, that his stratagem had been discovered.

'Upon him—at the risk of your lives!'—cried the officer:—and, on the instant, one of the soldiers moved rapidly towards the further wall; upon which the sergeant, apprehending the seizure of the weapons, sprang forward in such a manner as would have brought his body immediately before them, but a decayed plank in the floor caught his foot and he fell to his knee. It was a lucky accident,—for the discharge of a pistol by the officer, planted a bullet in the log of the cabin, which would have lodged, full in the square breast of the gallant Horse Shoe, if he had retained his perpendicular position. His footing, however, was recovered almost as soon as it was lost, and the next moment found him bravely posted in front of the fire-arms, with his own weapon thrust almost into the face of the foremost assailant. The hurry, confusion and peril of the crisis did not take away his self-possession,—but he now found himself unexpectedly thrown into a situation of infinite difficulty, where all the chances of the fight were against him.

'Back men, and guard the door,'—he cried out as if again addressing his troop.—'Sir, I will not be answerable for consequences if my troops once come into this house. If you do hope for quarters give up on the spot.—'

'His men have retreated,'—cried one of the soldiers.—'Upon him boys!—and instantly two or three pressed upon the sergeant, who seizing his rifle in both hands, bore them back by main force until he had thrown them prostrate on the floor.—'

He then leaped towards the door with the intention of making good his retreat.

'Shall I let loose upon them, captain?' said Andrew Ramsay, now appearing most unexpectedly to Robinson, at the door of the hut. 'Come on my brave boys, he shouted as he turned his face towards the field.

'Keep them outside of the door,—stand fast,'—cried the doughty sergeant again, with admirable promptitude, in the new and sudden posture of his affairs caused by this opportune appearance of the boy. 'Sir you see that you are beaten—let me warn you once more to save the lives of your men, its onpossible for me to keep my people off a minute longer. What signifies fighting fire to one?'

During this appeal the sergeant was ably seconded by the lad outside, who was calling out first on one name and then on another, as if in the presence of a troop. The device succeeded, and the officer within, believing the forbearance of Robinson to be real, at length said—'

'Lower your rifle, sir. In the presence of a superior force, taken by surprise and without arms, it is my duty to save bloodshed. With the promise of fair usage, and the rights of prisoners of war, I surrender this little foraging party under my command.'

'I'll make the terms agreeable,' replied the sergeant. 'Never doubt me, sir. Right hand file, advance and receive the arms of the prisoners.'

'I'm here captain,'—said Andrew in a concited tone as if it were a mere occasion of merriment;—and the lad quickly entered the house and secured the weapons, retreating with them some paces from the door.

'Now, sir,'—said Horse Shoe to the ensign,—'your sword, and what ever else you mought have about you of the ammunitions of war!'

The officer delivered up his sword and a pair of pocket pistols.

'Private property, I presume, will be protected,' he said.

'Ondoubtedly,' replied Robinson: 'your name? if I mought take freedom,?—'

'Ensign St. Jeremyn, of his Majesty's seventy-first regiment of Light Infantry,?—'

'Ensign, your sarvant,'—added Horse Shoe, aiming at an unusual exhibition of politeness.—'You have defended your post like an old sodger, although you ha'n't much beard on your chin;—I'll certify for you. But, seeing you have given up, you shall be treated like a man who has done his duty. You will walk out now and form yourselves in a line before the door. I'll engage my men shall do you no harm;—they are of a marcful breed.'

When the little squad of prisoners submitted to this command, and came to the door, they were stricken with the most profound astonishment to find, in place of a large detachment of cavalry which they expected to see, nothing but one horse, one man and one boy. Their first emotions were expressed in curses, which were even succeeded by laughter from one or two of the number. There seemed to be a disposition on the part of some, to resist the authority that now controlled them; and sundry glances were exchanged, which indicated a purpose to turn upon their captors. The sergeant no sooner perceived this, than he halted, raised his rifle to his breast, and, at the same instant gave Andrew Ramsay an order to retire a few paces, and to fire one of the captured pieces at the first man who opened his lips:

'By my hand,'—said he,—'if I find any trouble in taking you, all five, safe away from this here house, I will thin your numbers with your own muskets! And that's as good as if I had sworn to it.'

'You have my word sir,'—said the Ensign.—'Lead on—we'll follow.'

'By your leave—my pretty gentleman—you will lead, and I'll follow,'—replied Horse Shoe.—'It may be a new piece of drill to you—but the custom is to give the prisoners the post of honor, and to walk them in front.'

'As you please, sir,'—answered the Ensign.—'Where do you take us?'

'You will march back the road you came,'—said the sergeant.

Finding the conquerer determined to execute summary martial law upon the first who should mutiny, the prisoners now marched in double files from the hut, back towards Ramsay's—Horse Shoe, with Captain Peter's bridle dangling over his arm, and his gallant young auxiliary, Andrew, laden

with double the burden of Robinson Crusoe, (having all the fire arms packed upon his shoulders,) bringing up the rear. In this order, victors and vanquished returned to David Ramsay's.

'Well, I have brought you your ducks and chickens back, mistress,' said the sergeant, as he halted his prisoners at the door; 'and what's more, I have brought home a young sodger that's worth his weight in gold.'

'Heaven bless my child!—my boy, my brave boy!' cried the mother, seizing the lad Andrew in her arms, and unheeding any thing else in the present perturbation of her feelings. 'I feared ill would become of it: but Heaven has preserved him. Did he behave handsomely, Mr. Robinson? But I am sure he did.'

'A little more venturesome, ma'am, than I wanted him to be,' replied Horse Shoe. 'But he did excellent service. These are his prisoners, mistress Ramsay—I should never have got them, if it had not been for Andy. In these drumming and firing times, the babies suck in quarrel with their mother's milk. Show me another boy in America that's made more prisoners than there was men to fight with them—that's all! He's a first rate chap, mistress Ramsay—take my word for it.'

#### EUROPEAN INTELLIGENCE.

**LATER FROM ENGLAND.**—We received on Saturday evening files of London and Liverpool papers, to the 26th and 27th inclusive, by the packet *INDEPENDENCE*, CAPT. NYE.

The Francis Depau, Capt. Robinson, from Havre, whence she sailed on the 19th May, also arrived on Saturday, bringing our files of papers also, which, however, are of little interest, as we have several days later dates by way of London.

We do not find in any of the papers one word in relation to the indemnity bill. The entire attention of the French people is directed to the trial of Lyons rioters, which proceeds very slowly.

The accounts from Spain are any thing but cheering to those who desired the overthrow of Carlos.

Of England it may be said, *stocks have fallen*.

"BRING FLOWERS, BRING FLOWERS."—Felicia Hemans is dead, after long suffering. But she cannot all die—while tender and beautiful images and gentle affections, expressed in genuine poetry, can confer immortality.

**DEATH OF MRS. HEMANS.**—Died, on Saturday evening last, in Dawson street, Dublin, after a long and painful illness, which she bore with that cheerfulness and pious resignation which might have been expected from her writings and her character, Mrs. Hemans.—[Dublin Mail.]

**MRS. BUCKWORTH.**—It is stated in an Irish paper, that this admired writer—now no longer young—had by an accidental fall, broken her leg.

Yesterday a public meeting was held in the Mechanics' Institution, for the purpose of agreeing on a petition to the House of Commons for the repeal of the stamp tax on newspapers, Mr. Wakley, M.P., in the chair. The meeting was numerously attended. Mr. Roebuck, M.P., moved the first resolution, which was seconded by Mr. O'Connor, M.P. Both gentlemen addressed the meeting in speeches, which were greatly applauded. The resolutions were unanimously agreed to; a petition, founded upon them, to the House of Commons, was likewise agreed to, and Mr. Wakley requested to present it. Letters were read from Lord Brougham, Mr. Hume, Col. Evans, Mr. Cobbett, Sir S. Walley, and Mr. T. Duncombe, who had been invited to attend, declaring their concurrence in the object of the meeting, and regretting their inability to attend.—[Times.]

**LONDON, May 21.**—We gave on Monday an account of the abrupt manner in which the Belgian Chambers had been brought to the close of their labors. Our Brussels correspondent's letter, which appears in another column, contains some remarks relative to the causes of that occurrence, which will not be read without interest. The session has lasted six months, during which period it has done but little for purposes of public utility. The Chamber of Deputies has held 119 sittings, of which fifty-three were entirely devoted to the communal law. The other sittings were taken up with long dis-

cussions on the budgets and the law of expropriation.

#### TURKEY.

The sailing of the Sultan's fleet from the Dardanelles for Tripoli is confirmed. It left the Straits on the 28th, with a force calculated not to exceed 3000 or 4000 men.

#### PERSIA.

Letters from Persia bring accounts that the greatest anarchy prevails in that country. Mohamet Miza has appeared at the head of 60,000 men and 60 pieces of cannon, before the gates of Teheran, where he proclaimed himself King. Prince Shah, Governor of the town, wished to oppose his entry, but was obliged to retire, owing to Ali Yankhan, general of his army declaring in favor of Mohamet.

**LONDON, Monday, May 25.**—The *Allgemeine Zeitung* states, that the Shah of Persia had entered Ispahan in triumph, and that the civil war in that kingdom might be considered at an end.

**LATER FROM EUROPE.**—By the London packet *Philadelphia*, of 1 ult. papers to 31st May are received:

The affairs of Spain furnish the chief topic of interest, and it now seems certain that the rumors heretofore treated rather as stockjobbing inventions, than as founded in truth, of the growing strength of the Carlists, and the proportionate sinking of the Queen's cause, are confirmed.

The Queen has finally applied for the aid stipulated in her behalf by the quadruple treaty; and we are to expect to see a Portuguese force from one quarter, and a French force from another, enter Spain, while England shall have a fleet on the coast to intercept supplies to the Carlists. These, at least, are the stipulations of the treaty, if they be complied with. It is said, however, that *Louis Philippe* is by no means anxious to fulfil his part, of sending an army of fifty thousand Frenchmen into Spain, to sustain a cause which, as not being well looked upon by the Northern powers, he, too, is careless about.

In England the Ministry have sustained another defeat in their candidate for South Staffordshire, Sir E. Goodricke, Tory, being elected, after a hard contest, over Col. Anson, the Ministerial candidate.

A riot ensued at Wolverhampton, which the troops were called in to suppress. They fired upon, and charged the mob, wounding several but not killing any.

Owing to the extent of gambling in foreign securities, especially in Spanish Bonds, great derangements occurred on the London Stock Exchange on settling day, and immense losses were sustained.

From Paris, the dates are of 26th May. Nothing more of our indemnity bill in the House of Peers—which House indeed is said in an extract to have adjourned *sine die*. That, however, is evidently an error—though they may possibly have adjourned the trial of the conspirators.

From late official returns it appears that the number of curates in England, whose salary amounts only to 80l per annum, or less than \$400 is five thousand two hundred and eighty-two! that, too, in a land where the income of the bishop is from \$20,000 to \$100,000 per annum.

**SLAVE TRADE.**—On the motion of Mr. Buxton, in the House of Commons, an address to the King was agreed to, requesting his Majesty to take effectual measures to put an end to the slave trade, by endeavoring to form such treaties with foreign nations as will extend the limits of the right of searching slave vessels to the whole of the Western and Eastern coasts of Africa and the island of Madagascar, allow the vessels captured to be broken up, and declare the trade in slaves to be piracy. Mr. Hume seconded the motion; which Mr. Spring Rice did not oppose; though he said that treaties were actually pending with Spain and Por-

tugal, having for their object the accomplishment of Mr. Buxton's views.

Mr. Wyse obtained leave to bring in a bill to establish a Board for the advancement of education in Ireland. The object of Mr. Wyse appeared to be to extend the benefits of the Government plan now in operation.

The members of the London Mechanics' Institute assembled on Wednesday, at their theatre in Southampton Buildings. Among the gentlemen on the platform, were Sir Francis Burdett, Mr. Hume, Mr. Harvy, Mr. Tooke, and Mr. Robert Owing. Dr. Birkbeck took the chair, and delivered the prize to the members. Sir Francis Burdett addressed the meeting in praise of the objects of the Society; after which several resolutions were carried.

**A TURK CONFORMING TO CHRISTIAN USAGES.**—A dinner was given by the merchants of London engaged in the Levant trade, to Nourri Effendi, the recently arrived Ambassador from the Court of Turkey. It was attended by upwards of a hundred of the Levant merchants; among whom were Sir J. R. Reid, M. P., Mr. Robinson, M. P., and the Lord Mayor. The chairman was Mr. Grant. He explained, that as Nourri Effendi understood no language but his own, and as none of the suite were very conversant with English, it would be necessary for him to propose the toasts in French; his Highness the Prince of Samos, who sat next to his Excellency, having kindly undertaken to convey their meaning in Turkish. In the course of the evening, the reserve of the Turk yielded to the conviviality which reigned around, and among the happiest of those present none appeared more happy than Nourri Effendi; who drank wine and cheered as the toasts were given, as heartily as any English foxhunter, in happy forgetfulness of the Prophet's commands.

The eight Metropolitan Water Works, which supply London, furnished in 1833, thirty-five million gallons daily! Upwards of three millions sterling, or about thirteen millions and a half dollars, had been expended on the works—yet a fresh water river, the Thames, runs through the city.

At the beginning of the present century (1800) there were not more than forty Catholic Chapels throughout England. There are now (1835) more than five hundred! some of them built on a large scale—quite cathedrals—and it is also true that these edifices are multiplying every month.—[Dublin Journal.]

**FRENCH ARMY.**—The following data, from the *Annuaire Militaire* show that the estimates of the French army are smaller than the last year of the Restoration. In 1830 the infantry consisted of 94 battalions of the guards, 64 regiments of the line, making 192 battalions; 29 regiments of light infantry, consisting of 44 battalions; foreign legion, 3 battalions; 4 Swiss regiments, or 12 battalions:—total, 275. In 1834, 67 regiments of the line, or 201 battalions; 21 light infantry, or 63 battalions; foreign legion 6 battalions:—total 270, being 5 battalions less than in 1830. The reduction is still more sensible in the cavalry. In 1830, cavalry of the guard, 8 regiments or 48 squadrons; 4 companies of body guards, or 8 squadrons; gendarmes d'élite, 2 squadrons; carabiniers, 12 squadrons; 10 regiments of cuirassiers, or 48 squadrons; dragons, 12 regiments, or 72 squadrons; chasseurs, 18 regiments, or 108 squadrons; hussars, 6 regiments, or 24 squadrons:—total 322. In 1835, 50 cavalry regiments, or 250 squadrons; 72 less than in 1830.—[Baltimore Gazette.]

#### DOMESTIC INTELLIGENCE.

Mr. LIVINGSTON, the Minister of the United States to France, arrived in this city on Friday night from New York, and is still here. On his way to this city, he received various marks of regard from his fellow citizens, and, among them, an invitation to a Public Dinner, which he accepted, from a number of political friends at Philadelphia.—[Nat. Intelligencer.]

We understand that Dr. Samuel Moore has resigned the office of Director of the Mint of the United States, to take effect on the first of the next month, and that Robert M. Patterson, M. D., of the University of Virginia, has been appointed to succeed him.—[Globe.]

**LARGE DIVIDEND.**—The Atlantic Insurance Company of this city, yesterday, declared a divi-

dend of ten per cent. for the last six months, payable on the 7th inst.

**LAW OF PRINTERS.**—We learn from a gentleman who was present, that in the case of Arnolds vs. Clifford, tried at Newport last week, Judge Story, upon an incidental point, stated, that a promise on the part of the writer of a libel to indemnify the printer of it against any damage he might sustain for printing, could not be enforced. Even if a bond were taken, that would be void.—[Daily Ad.]

The curious phenomenon of the Water Spout was witnessed on Sunday evening, about 6 o'clock, by hundreds of our fellow-citizens. It was formed near the lower extremity of the Ohio Falls. According to those, who saw the formation, a cone, in the shape of a trumpet, descended towards the river from a thick dark thunder-cloud, and at the same time, the agitated waters beneath whirled round and ascended with a spiral motion in the form of vapor, till they united with the cone of the cloud, when the whole column moved rapidly and majestically about a mile and a half up the river, where it struck the woods in Indiana, nearly opposite to this city, and disappeared. The whirlwind then passed over a part of Jeffersonville, unroofing houses and doing other damage, but soon struck the river a second time, forming another waterspout, which crossed the river to the Kentucky side and disappeared a short distance above Geiger's Mills. On both sides of the river, the whirlwind's path is marked with desolation.—[Louisville Journal.]

**TORNADO.**—We learn by a letter from a gentleman in Liberty, in this county, that the eastern part of that town and the western part of Never-sink were, on Friday evening last before it was quite dark visited by a tornado, unprecedented in violence in that part of the country. It first vented its fury on the farm of Judge Cray, tearing up by the roots some of his most valuable apple trees, thirty or forty in number, destroying the shade trees near his dwelling house, and prostrating a large portion of his fences. The next place where much damage was done was the farm of Mr. Benjamin B. Krum, where two large hay houses were levelled with the ground; his barn was also injured; a few sheep were also killed. The hurricane thence passed to the farm of Mr. Phillip Leroy, killing a cow in its progress, and tearing from the ground rocks which, it is said two yoke of oxen could not have drawn out. About two miles further a new barn, belonging to Mr. Bently was blown down, and on the farm adjoining, belonging to Doctor B. Wales, a large building enclosing a cider mill and press, and another small building were entirely demolished. The house of Dr. Wales also received some injury. We have heard nothing of the further progress of the tornado in this direction and it seems soon after to have spent its force.—The stream of wind seems to have been about fifteen rods in width, accompanied with a dreadful noise, vivid and continued flashes of lightning and heavy thunder. The violence of the wind is almost beyond belief. Pieces of the cider mill of Dr. Wales, and the barn of Mr. Bently were carried to the distance of nearly a mile. Apple trees were blown several rods from the places where they stood, and in some places, it is stated that the grass was cut as smooth as could have been done with a scythe.

We learn from another source that the tornado extended its ravages into the town of Rockland.—A barn belonging to the Messrs. Waterbury was prostrated, and a large quantity of timber trees were blown down. A cow belonging to Mr. Israel Dodge and an ox of Mr. F. Smith were killed. We have not heard that any person has been either killed or injured.—[Monticello Herald.]

On Saturday afternoon our city was visited by a very heavy gust of rain, accompanied with thunder and lightning. The rain commenced falling about half past six, and was preceded by a violent whirlwind, which passed over without doing any material damage to property. In Albemarle street, two three-story houses, covered with tin, were unroofed, and a poplar tree immediately in front of them was blown down, but no person was hurt. The houses were occupied by Mr. John Fisher, and Mrs. Briscoe.

We regret to state the occurrence of a very serious accident immediately after the rain commenced. A number of persons took shelter in the Court House, and while there the electric fluid struck one of the chimneys and knocked it down among them. One of the bricks fell on the head

of a son of Chief Justice Marshall, and fractured his skull. Medical aid was immediately called, and we learn that though he now lies in a very dangerous condition, there is nevertheless some hope that he may survive.—[Baltimore American.]

**STEAM FACTORY.**—In the town of Newport are two Steam Cotton factories now in operation, and another is immediately to be built upon a large scale, being two hundred feet long by forty wide.—Those engaged in these enterprises say they have by practice demonstrated that it is cheaper to use steam power in the midst of a dense population, than to use water power, which often makes it necessary not only to build a factory but a town also. There is transportation, and various other items, which come into the account on one side or the other.—[Jour. of Commerce.]

Great excitement is said to prevail in Matamoras among the foreigners in consequence of the imprisonment of Messrs. Boyd and Lee, American merchants, and the subsequent harsh treatment they received. The Mercurio of Matamoras says that a few days before, the Parish Priest while conveying the sacrament in the usual cortege to the house of a sick person, was met by the above named gentlemen, who did not pay to the procession those marks of reverence which are customary. The Priest, irritated, appealed to the spectators, ordered them to seize Messrs. Boyd and Lee, and throw them into dungeon, which was done without the least hesitation on the part of the people, or interference on the part of the magistrates.

A correspondent of the Army and Navy Chronicle furnishes the following information respecting the movements of the U. S. Dragoons on our western frontier.

PORT LEAVENWORTH, 29th May, 1835.

Dear Sir:—For the information of your military readers, as well as those who have relatives and friends amongst the dragoons at this post, you can, if you think proper, say, in your next Chronicle, that Captain Hunter, with his company "D," about forty men, and wife, left here yesterday for his summer's tramp, as directed by the general order for the disposition of the dragoon regiment.—Mrs. H. has a saddle horse and small covered dearborn for her own use, and intends passing the summer in the field with her husband; she is an amiable and charming lady, and, as you may well conceive, a good soldier.

The officers with Captain H. are Lieutenants Moore and Ury, the latter acting commissary of subsistence, &c., a citizen, Doctor Wood, is employed for this company.

Colonel Dodge, with the remaining three companies "A," "C," and "G," consisting of about 100 men, in all, marched to-day. The officers with him are Lieutenants Kingsbury, Acting Adjutant; Terrett, Assistant Commissary of Subsistence; Lieutenant Steen, Ordnance Officer, in charge of two swivels mounted on wheels; and Assistant Surgeon B. F. Fellowes, U. S. Army; Captains Ford and Duncan, and Lieutenant Lupton, commanding companies; and Lieut. Wheelock, doing duty in company "C."

Colonel Dodge's route will probably be by the way of the Otto village, near the Platte river and Council Bluffs, to the "Pawnees" and "Aurickaree's;" and from thence the colonel intends to penetrate, as far as the season will admit of, into the "Blackfoot" country, to the north; and, if possible, obtain an interview with these Indians. He will also seek a meeting with the "Crows," who inhabit the region to the southwest of the Blackfoot, in the vicinity of the Rocky Mountains, near the head waters of the Yellowstone river.

Colonel Dodge takes with him, on pack mules, provisions for sixty days, and about twenty head of beef cattle. Two ox teams, loaded with flour, also go with the command as far as the Pawnee villages, when the flour will be distributed amongst the packs, and the teams discharged.

Major Dougherty, Indian Agent, who is intimately acquainted with the country over which the troops will march, and so well and favorably known for his acquaintance with the Indians, has volunteered his services to Colonel Dodge, and will accompany the dragoons on their expedition.

The horses are in good order, and the men in fine spirits, and all the officers anticipate an interesting tramp.

[From the Providence (R.I.) Journal.]

**THE LAST OF THE TEA PARTY.**—Last Friday we had the satisfaction of seeing and conversing with the only survivor of that daring band of patriots, who offered the first open resistance to the oppressions of the British Crown, the venerable Joseph Robert Twelves Hughes. Mr. Hughes was passing through Providence, from his residence Otsego county, New York, to attend the anniversary celebration of the independence of his country at at Boston, whither he had been invited as the city's guest.

He was born in Massachusetts on the 5th of September, 1735, and on the 4th of July will want only sixty-three days of being one hundred years old.—His youngest son, the fifteenth of his children, and apparently about forty years old, was with him.—We have seen many men of seventy who appeared as old as Mr. Hughes. His voice was strong, his stature quite erect, and his step comparatively firm. He was evidently, even at this age, a brave, high spirited, warm hearted man, whose tongue was never controlled by ceremony, and whose manners have not been moulded by the fashion of any day. His etiquette may be tea party etiquette, but it was not acquired at tea parties in Beacon street or Broadway. The venerable Moses Brown, almost his compeer in years, called upon him and was introduced.—The contrast between the mild, gentlemanly mien of the patriarchal Friend, and the rough address of the veteran hero, was strikingly apparent.—The one was an apt personification of brazen fronted War, the other the dignified representative of gentle Peace.

During the Revolutionary war Mr. Hughes sailed out of Providence in an armed sloop, owned by John Brown, captured three prizes, and brought them into port. Our interview with him was so short that we had not an opportunity of ascertaining the other achievements of his protracted life.

The first person he inquired for on arriving here was the late Mr. George Freeman of this city, whom he says he named when an infant, and who died about ten years ago, at an age of upwards of fifty years.

**EXPEDITIOUS TRAVELLING TO RUSSIA.**—A passenger who arrived at Havre in the packet ship Charlemagne, embarked the same day in the Steam packet for Hamburg, which performs the passage in 50 hours, when they take the stage for Lubeck, drive there in six hours, and then embark in the General Steam Navigation Co.'s Packet for St. Petersburg, where they arrive on the fourth day—thus making a voyage from New-York to St. Petersburg, in less than 25 days.—[Jour. of Com.]

The Captain of the brig Falcon, at Baltimore, which left Rio Grande May 13, reports that one tenth of the inhabitants died in the months of March and April, of Cholera. Markets for all kinds of American produce glutted, and country produce very scarce and high.

#### On the Loss of a Child in Infancy.

"They only can be said to possess a child forever, who have lost one in infancy."

Our beautiful child we laid amidst the silence of the dead, We heaped the earth and spread the turf above the Cherub head;

We turned again to sunny life, to other ties as dear, And the world has thought us comforted when we have dried the tear.

And time has rolled his onward tide, and in his ample sweep, Has poured along the happiest paths, vicissitudes and change.

The flexile forms of infancy their earliest leaves have shed, And the tall and stately forest trees are waving in their stead. We guide not now our children's steps as we were wont before,

For they have sprung to warrior men, they lean on us no more, We gaze upon the lofty brow, and time sad thought have cast

A shade through which we seek in vain the memory of the past.

And do we mourn the utter change which mocks our memory here?

Oh no! 'tis but the answered wish of many a secret prayer, Centre of all our dearest hopes, we live but in their arms; But our love, as to a little child, how can it be the same?

We still have one, an only one, secure in sacred trust; It is the lone and lovely one, that's sleeping in the dust; We fold it in our arms again; we see it by our side, In the helplessness of innocence, which sin has never used.

All earthly trust, all mortal years, however light they fly, But darken on the glowing cheek and dim the eagle eye; But thee, our bright, unwithering flower, our spirit's hoarded store,

We keep through every chance and change, the same forever more.

**CIRCULAR.** To ENGINEERS and Superintendents of Railroads and Canals.—I am preparing to issue a new edition of my RAILROAD AND CANAL MAP; and being desirous to correct the errors of the first edition, I take the liberty to request the ENGINEER, or SUPERINTENDENT, of every Railroad and Canal in the UNITED STATES, to furnish me at his earliest convenience with a full and precise account of the condition of the railroad under his direction or charge. He is requested to state the length of the road, the number of miles completed, the elevation it surmounts, the radius of its curves, the style of its construction, its average cost per mile, the number, if any, of inclined planes, with stationary engines—in short, every thing which may be of interest to engineers, or others who may be connected with the subject of Railroads and Canals.

To such as comply with the above request, and furnish the desired information previous to the first of August next, a copy of the new edition of the Railroad and Canal Map, will be sent, by mail or otherwise, as may be directed, as soon as completed.

D. K. MINOR.

New-York, June 27, 1835.

#### RAILROAD JOURNAL AND ADVOCATE OF INTERNAL IMPROVEMENTS.

This work is published once a week, in quarto form of EIGHT pages, devoted mainly to the subject of internal improvements, in all its various modes and forms. Three volumes were completed in December, 1834, and the 4th volume is now in progress.

Terms, \$3 a year, IN ADVANCE. Previous volumes same price; full set of four volumes, \$12.

#### RAILROAD AND CANAL MAP,

Or a Map of the United States, 24 by 40 inches, on which is delineated all the Railroads and Canals in use, or in course of construction, and most of those in contemplation; together with a concise description of, or reference to, each, and containing over 70 pages of letter press. The map is on bank note paper, and put up in pocket form, with morocco cover, or in paper cover, and may be sent by mail to any part of the country. Price \$2.

#### MECHANICS' MAGAZINE, AND REGISTER OF INVENTIONS AND IMPROVEMENTS.

This work has nearly completed five volumes. It is published monthly, in numbers of 64 pages each, in large octavo form, and forms two good sized volumes a year, of 334 pages each.

This work is STEREOTYPED from the first number, and therefore any number of copies may be obtained from commencement, if desired. It has many able correspondents, who furnish original communications, in addition to its selections from the best European periodicals of the day, with numerous engravings and illustrations of the subjects on which it treats. The Mechanics' Magazine may be considered as one of the permanent periodicals of the country. Price, \$3 per annum, IN ADVANCE. Previous volumes \$1.50 each.

#### THE APPRENTICE'S COMPANION—

A monthly publication, in large octavo form, of sixteen pages each number—designed to persuade APPRENTICES, and others, to habits of INDUSTRY, TEMPERANCE, and FRUGALITY—is published at the office of the MECHANICS' MAGAZINE, No. 35 Wall street, New-York, for FIFTY CENTS a year—for 12 numbers—by D. K. MINOR.

\* All letters must be postage paid. Eleven numbers sent to one address for \$5,—and TWENTY-THREE for \$10. D. K. M.

#### NEW-YORK FARMER AND AMERICAN GARDENER'S MAGAZINE.

This work is devoted mainly to AGRICULTURE and HORTICULTURE; it, however, treats upon various other subjects more or less connected with them. It is now in its 8th volume, or 3d volume, new series, and is designed to be made equal to any work of the kind in this or any other country. No reasonable expense will be spared, either to secure the best writers the country affords, or to furnish engravings and illustrations. It is published monthly in large octavo, 32 pages per month, at \$3 per annum, and when paid in advance eight additional pages per month are given. Vols. 6 and 7, or 1 and 2, new series, \$3 per volume.

#### QUARTERLY JOURNAL OF AGRICULTURE, MECHANICS, AND MANUFACTURES.

This work is composed of the choicest articles of the three preceding works; its character may therefore be understood by reading those advertisements. It has been published at \$3, but will be, hereafter, at \$4 per annum—always in advance; each quarterly number to contain about 220 pages.

These works may all, or either of them, be had of S. Blydenburgh, 96 North Pearl street, Albany; D. Hale, 124 Washington street, Boston; Fessenden, Philadelphia; or of the Proprietor and Publisher, D. K. MINOR,

35 Wall street, New-York.

#### PARTNER WANTED.

Wanted, a partner in an extensive Printing Establishment. No one need apply who is not a thoroughbred printer, competent to superintend and direct an office in which upwards of 30 persons are employed, and able to furnish \$3000 cash capital. The best of references will be given and required. Letters, with real name, may be addressed to P. P. P., Post Office, New-York, postage paid, and they will be promptly attended to. May-17

#### RAILROAD IRON.

500 Tons Railroad Iron, 2 inch by 1/2, with Spikes and Spiking Plates to match, for sale by

WM. G. BULL & CO.  
74 Wall-st.

#### RAILROAD CASTINGS.

MANY & WARD, Proprietors of the Albany Eagle Air Furnace and Machine Shop, will make to order car wheels, chairs and kners, and every other description of castings required for railroads. R-1y feb14

#### TO TUNNEL MINERS, DRILLERS, &c.

Wanted, immediately, 40 Tunnel Miners, (Cornish Miners will be preferred,) 80 Drillers, 50 Laborers, and two experienced Mine Blacksmiths, on the New York and Harlem Railroad, about five miles from the City. Liberal wages will be given, and cash payments made every fortnight. Apply at Mr. FOWLER'S, St. John's Hall, Frankfort street, New-York.

JOHN BUTTER, Contractor.  
The Albany Argus, Philadelphia U. S. Gazette and Pennsylvania, will please copy this, and send their bills to the Railroad Company, 14 Wall street, New-York. 23-17

#### PATENT HAMMERED SHIP, BOAT, AND RAILROAD SPIKES.

Railroad Spikes of every description required, made at the Albany Spike Factory. Spikes made at the above Factory are recommended to be public as superior to any thing of the kind now in use. Ship and Boat Spikes made full size under the head, so as not to admit water. Orders may be addressed to Messrs. ERASTUS CORNING & CO., Albany, or to THOMAS TURNER, at the Factory, Troy, N. Y. sept.12 ly

#### PATENT RAILROAD, SHIP AND BOAT SPIKES.

The Troy Iron and Nail Factory keeps constantly for sale a very extensive assortment of Wrought Spikes and Nails, from 3 to 10 inches, manufactured by the subscriber's Patent Machinery, which after five years' successful operation and now almost universal use in the United States (as well as England, where the subscriber obtained a Patent,) are found superior to any ever offered in market.

Railroad Companies may be supplied with Spikes having countersink heads suitable to the holes in iron rails, to any amount and on short notice. Almost all the Railroads now in progress in the United States are fastened with Spikes made at the above named Factory—for which purpose they are found invaluable, as their adhesion is more than double any common spikes made by the hammer.

All orders directed to the Agent, Troy, N. Y., will be punctually attended to.

HENRY BURDEN, Agent.

Troy, N. Y. July, 1831.  
Spikes are kept for sale, at factory prices, by 1. & J. Townsend, Albany, and the principal Iron Merchants in Albany and Troy; J. I. Brower, 229 Waterstreet, New-York; A. M. Jones, Philadelphia; T. Janvier, Baltimore; Degrand & Smith, Boston.

Railroad Companies would do well to forward their orders as early as practicable, as the subscriber is desirous of extending the manufacturing so as to keep pace with the daily increasing demand for his Spikes. 132-am

H. BURDEN.

#### PATERSON AND NEW YORK RAILROAD LINE. SUMMER ARRANGEMENT FOR 1835.

Passengers will leave Paterson, New York, by Jersey City

son at	Ferry at
6 1/2 o'clock, A. M. by Steam	5 1/2 o'clock, A. M. by Horses

New York at 8 o'clock, A. M. by Steam,	8 1/2 " " " " " " " "
9 1/2 " " " " " " " "	8 1/2 " " " " " " " "
6 1/2 " " " " " " " "	8 1/2 " " " " " " " "

Ticket Office in Paterson, corner of Congress and Main streets, opposite "Congress House".  
Ticket Office in New York, 75 Courtland st.

Passengers with Tickets will have a preference in seats. Fare from Jersey City, 50 Cents.

Transportation Cars will also ply three times a day each way.

As the Ferry boats do not leave New York precisely at the above times, it is recommended to passengers to procure their tickets and to be at the Ferry a few minutes before the stated hours of departure.

PATRICK COUGHLIN, Agent  
in New York.

#### STEPHENSON.

Builder of a superior style of Passenger Cars for Railroad.

No. 264 Elizabeth street, near Bleecker street, New-York.

RAILROAD COMPANIES would do well to examine these Cars; a specimen of which may be seen on that part of the New-York and Harlem Railroad now in operation. J36 17

#### RAILROAD CAR WHEELS AND BOXES, AND OTHER RAILROAD CASTINGS.

Also, AXLES furnished and fitted to wheels complete at the Jefferson Cotton and Wool Machine Factory and Foundry, Paterson, N. J. All orders addressed to the subscribers at Paterson, or 60 Wall street, New-York, will be promptly attended to.

Also, Flange Tires turned complete.

J8 ROGERS, KETCHUM & GROSVENOR

#### RAILWAY IRON.

95 tons of 1 inch by 1/2 inch.	Flat Bars in lengths of
200 do. 1 1/2 do. do.	14 to 15 feet, countersunk
40 do. 1 1/2 do. do.	holes, endcut at an angle
800 do. 2 do. do.	of 45 degrees, with appli-
800 do. 2 1/2 do. do.	cating plates and nails to
	soon expected.

350 do. of Edge Rails of 36 lbs. per yard, with the requisite chairs, keys and pins.

Wrought Iron Rims of 30, 33, and 36 inches diameter for Wheels of Railway Cars, and of 60 inches diameter for Locomotive wheels.

Axles of 2 1/2, 2 3/4, 3, 3 1/4, and 3 1/2 inches diameter for Railway Cars and Locomotives of patent iron.

The above will be sold free of duty, to State Governments and Incorporated Governments, and the Drawback taken in part payment.

A. & G. RALSTON.

9 South Front street, Philadelphia.  
Models and samples of all the different kinds of Rails, Chairs, Pins, Wedges, Spikes, and Splicing Plates, in use both in this country and Great Britain, will be exhibited to those disposed to examine them. d17meowr

#### SURVEYORS' INSTRUMENTS.

Compasses of various sizes and of superior quality warranted.

Leveling Instruments, large and small sizes, with high magnifying powers with glasses made by Troughton, together with a large assortment of Engineering Instruments, manufactured and sold by

E. & G. W. BLUNT, 154 Water street, corner of Maiden lane.

#### SURVEYING AND ENGINEERING INSTRUMENTS.

The subscriber manufactures all kinds of Instruments in his profession, warranted equal, if not superior, in principles of construction and workmanship to any imported or manufactured in the United States; several of which are entirely new, among which are an Improved Compass, with a Telescope attached, by which angles can be taken with or without the use of the needle, with perfect accuracy—also a Railroad Goniometer, with two Telescopes—and a Leveling Instrument, with a Goniometer attached, particularly adapted to Railroad purposes.

WM. J. YOUNG.

Mathematical Instrument Maker,  
No. 9 Dock st., Philadelphia.

The following recommendations are respectfully submitted to Engineers, Surveyors, and others interested.

Baltimore, 1835.

In reply to the inquiries respecting the instruments manufactured by thee, now in use on the Baltimore and Ohio Railroad, I cheerfully furnish thee the following information. The whole number of Levels now in possession of the department of construction of thy make is seven. The whole number of the "Improved Compass" is eight. These are all exclusive of the number in the service of the Engineer and Graduation Department.

Both Levels and Compasses are in good repair. They have in fact needed but little repairs, except from accidents to which all instruments of the kind are liable.

I have found that thy patterns for the levels and compasses have been preferred by my assistants generally, to any others in use, and the Improved Compass is superior to any other description of Goniometer that we have yet tried in laying the rails on this Road.

This instrument, more recently improved with a reversing telescope, in place of the vane sights, leaves the engineer scarcely any thing to desire in the formation or convenience of the Compass. It is indeed the most completely adapted to lateral angles of any simple and cheap instrument that I have yet seen, and I cannot but believe it will be preferred to all others now in use for laying of rails—and in fact, when known, I think it will be as highly appreciated for common surveying.

Respectfully thy friend,

JAMES P. STABLER, Sup't of Construction of Baltimore and Ohio Railroad.

Philadelphia, February, 1835.

Having for the last two years made constant use of Mr. Young's "Patent Improved Compass," I can safely say I believe it to be much superior to any other instrument of the kind, now in use, and as such most cheerfully recommend it to Engineers and Surveyors.

E. H. GILL, Civil Engineer.

German town, February, 1835.

For a year past I have used Instruments made by Mr. W. J. Young, of Philadelphia, in which he has combined the properties of a Theodolite with the common Level.

I consider these Instruments admirably calculated for laying out Railroads, and can recommend them to the notice of Engineers as preferable to any others for that purpose.

HENRY R. CAMPBELL, Eng. Philad.
